and so on. Value distribution of meromorphic solutions of equation in the first Painlevé hierarchy (4.5.39) has been treated by Shimomura [164], He [61] and Li [118]. Some of the main results in these papers are as follows:

THEOREM 4.5.13. *Given $n \in \mathbb{N}$, let f be a meromorphic solution of* (4.5.39). *Then the following assertions follow*:

(1) *The solution f is transcendental meromorphic with double poles only and of order $\rho(f) \geqslant \frac{2n+3}{n+1}$.*
(2) *For each extended complex number a, $\delta(a, f) = 0$.*
(3) *The second main theorem for f takes the form of an asymptotic equality*

$$m(r, f) + \sum_{j=1}^{q} m\left(r, \frac{1}{f - a_j}\right) + N_1(r, f) + N\left(r, \frac{1}{f'}\right) = 2T(r, f) + S(r, f).$$

REMARK. It is a natural conjecture that $\rho(f) = \frac{2n+3}{n+1}$. Unfortunately, this remains open.

As for the *second Painlevé hierarchy*, we first define the operator

$$S[f] := 4f^2 + 4f'D^{-1}f - D^2$$

and then construct the algebraic differential equation

$$D^{-1}S^{m-1}[f]f' + zf + \alpha = 0, \tag{4.5.40}$$

where $\alpha \in \mathbb{C}$ is a parameter, for $m \in \mathbb{N} \setminus \{1\}$. This differential equation is of order $2m - 2$ and for $m = 2$ we obtain the second Painlevé equation (4.5.32), for $m = 3$ we get

$$f^{(4)} = 10f^2f'' + 10f(f')^2 - 6f^5 - zf - \alpha,$$

and so on. Now, the growth and value distribution of meromorphic solutions of equations in the second Painlevé hierarchy (4.5.40) has been investigated in two papers by Li and He [119,118]. Some of their results read as follows:

THEOREM 4.5.14. *Given* $m \in \mathbb{N} \setminus \{1\}$, *let* f *be a transcendental meromorphic solution of* (4.5.40). *Then the following assertions hold*:

(1) *All poles of* f *are simple and* $\delta(\infty, f) = 0$.
(2) *If* $\alpha \neq 0$, *then* $\delta(a, f) = 0$ *for each* $a \in \mathbb{C}$.
(3) *If* $\alpha = 0$, *then* $\delta(a, f) = 0$ *for each* $a \in \mathbb{C} \setminus \{0\}$ *and* $\delta(0, f) \leqslant 1/2$.

REMARKS.

(1) There exist no results concerning the growth of meromorphic solutions of (4.5.40), although it is natural again to conjecture that these functions are of finite order.
(2) It would be interesting to investigate the residues of the poles of f for the parameter values $\alpha = \varepsilon/2$, $\varepsilon^2 = 1$. This has been done in the case of $m = 3$, see [119], Theorem 2.4. Compare also with the corresponding results for (4.5.32), i.e. in the case of $m = 2$, see [51], Section 21.
(3) In the second Painlevé hierarchy as well, transcendental meromorphic solutions again have an asymptotic equality in the second main theorem in the form

$$m\left(r, \frac{1}{f}\right) + \sum_{j=1}^{q} m\left(r, \frac{1}{f - a_j}\right) + N_1(r, f) + N\left(r, \frac{1}{f'}\right) = 2T(r, f) + S(r, f),$$

where each $a_j \neq 0$, see [118], Theorem 3.1.

4.6. *Briot–Bouquet differential equations*

By Briot–Bouquet differential equations we understand autonomous differential equations in the complex plane of the form $P(f, f^{(k)}) = 0$, where P is a polynomial in both variables, having constant coefficients, of course. Investigations concerning Briot–Bouquet differential equations go back to a classical paper by Briot and Bouquet in 1856, where they claim that all meromorphic solutions of $P(f, f') = 0$ belong to one of the following classes of functions: (1) rational functions, (2) rational functions of e^{az} for some complex constant $a \neq 0$, (3) elliptic functions. Denoting this collection of meromorphic functions by $\mathfrak{W}$, one can show [79] that any meromorphic function $f \in \mathfrak{W}$ satisfies a Briot–Bouquet equation, see also [78]. In the reverse direction, this remains an open

CONJECTURE. *Any meromorphic solution in the complex plane of a Briot–Bouquet differential equation is in the collection* $\mathfrak{W}$ *of meromorphic functions.*

Concerning the existence of meromorphic functions for Briot–Bouquet differential equations, the following fact is classical: Denote by $S = S(P)$ the compact Riemann surface determined by the algebraic curve $P(u, v) = 0$. A necessary condition for the existence of a non-constant meromorphic solution f to $P(f, f^{(k)}) = 0$ is that the genus $g(S)$ of the Riemann surface S is either $g(S) = 0$ or $g(S) = 1$. The following partial result to the conjecture above are known:

THEOREM 4.6.1. *Let f be a meromorphic solution of a Briot–Bouquet differential equation $P(f, f^{(k)}) = 0$ of the first or second order, i.e. if $k = 1$ or $k = 2$. Then $f \in \mathfrak{W}$.*

REMARK. There are several presentations of this result in the classical literature of the 19th century. However, these proofs hardly can be accepted of being rigorous according to the present standards. For a modern proof, see [12], Theorems 1 and 5.

THEOREM 4.6.2. (See [37].) *Suppose f is a non-constant meromorphic solution of a Briot–Bouquet differential equation $P(f, f^{(k)}) = 0$, and let g be the genus of the Riemann surface determined by the algebraic curve $P(u, v) = 0$. Then the following assertions hold*:

(1) *If $g = 1$, then f is an elliptic function.*
(2) *If $g = 0$, k is an odd natural number and f is entire, then $f \in \mathfrak{W}$.*

REMARK. Observe that there is an extensive literature in the unit disc about the differential equation

$$f + \frac{zf'}{\beta f + \gamma} = h(z),$$

where β, γ are complex constants and $h(z)$ is an analytic function. This differential equation is said to be a Briot–Bouquet differential equation as well. We omit these investigations in this connection, as their main connection is to the subordination theory, and not so much to the theory of complex differential equations.

4.7. *Algebraic differential equations*

Algebraic differential equations

$$\Omega(z, f, f', \dots, f^{(n)}) = \sum_{\lambda \in I} a_\lambda(z) f^{\lambda_0} (f')^{\lambda_1} \cdots (f^{(n)})^{\lambda_n} = 0, \tag{4.7.41}$$

where Ω is a polynomial in the variables $f, f', \dots, f^{(n)}$ with meromorphic coefficients, and I is a finite index set, form an extensive field of research. However, open problems abound, and the overall impression is still somehow scattered. It seems to us that obtaining some coherence in the whole area needs to combine tools from various fields such as complex analysis and differential field theory. To get a quick overview of a number of open research problems in the field of algebraic differential equations, we refer to the problem collections [148–150] composed by Rubel.

While considering Eq. (4.7.41) below, we need some degree and weight notations as follows: The *degree* $|\lambda|$ of a single term in (4.7.41) will now be defined as

$$|\lambda| := \lambda_0 + \cdots + \lambda_n,$$

and its *weight* $\|\lambda\|$ as

$$\|\lambda\| := \lambda_0 + 2\lambda_1 + \cdots + (n+1)\lambda_n.$$

Of course, the degree and the weight of the whole Eq. (4.7.41) will then be defined as

$$|\Omega| := \max_{\lambda \in I} |\lambda|, \qquad \|\Omega\| := \max_{\lambda \in I} \|\lambda\|.$$

One of the key open problems in the field of algebraic differential equations is the following

CONJECTURE. *All meromorphic solutions of algebraic differential equations* (4.7.41) *with polynomial coefficients satisfy the growth inequality*

$$T(r, f) \leqslant a \exp_{n-1}(br^c),$$

where $\exp_1(z) \equiv e^z$, $\exp_{j+1}(z) := \exp(\exp_j(z))$, *and where* a, b, c *are positive real constants.*

This conjecture has been verified for the first order algebraic differential equations as shown by the classical result due to Gol'dberg [50]:

THEOREM 4.7.1. *All meromorphic solutions* f *of first order algebraic differential equations* $\Omega(z, f, f') = 0$ *with polynomial coefficients are of finite order of growth.*

REMARKS.

(1) As mentioned above, see the remark after Theorem 4.2.9, the order of transcendental meromorphic solutions is either zero, or a multiple of $1/2$ or of $1/3$, see [40].

(2) If f is an entire solution of $\Omega(z, f, f') = 0$ with polynomial coefficients, then $\rho(f) > 1/2$. This is an improvement, due to Strelitz [177], of a classical result by Pólya who proved that $\rho(f) > 0$. However, a meromorphic solution may well be of order zero, see an example in [107], pp. 234–236, due to Bank and Kaufman. We remark here that the claim $\rho(f) > 0$ remains true for entire solutions f of second order algebraic differential equations $\Omega(z, f, f', f'') = 0$ as shown by Zimogljad [197], while for algebraic differential equations of order $\geqslant 3$, examples of entire solutions of zero order have been constructed by Valiron.

Proceeding to first order algebraic differential equations with meromorphic coefficients, observe first that it is not possible to estimate the growth of meromorphic solutions in terms of the growth of the coefficients only, uniformly for all such equations, not even in the linear case. This follows of a somewhat surprising arbitrary growth theorem due to Bank in [2]:

THEOREM 4.7.2. *Given any strictly positive real function* Φ *on the positive real axis, there exists a meromorphic function* h *such that* h'/h *is of finite order and* $T(r_n, h) > \Phi(r_n)$ *for a sequence tending to* $+\infty$.

Some of the results describing quantities needed for such a uniform estimate are presented below. Such a uniform estimate in terms of the coefficients only may be found for entire solutions, see [107], Theorem 11.10:

THEOREM 4.7.3. *Let* $\Omega(z, f, f') = 0$ *be a first order algebraic differential equation with entire coefficients of finite order* $\leqslant \rho < \infty$. *Then all entire solutions* f *satisfy*

$$T(r, f) = \mathrm{O}(\exp r^{\rho+\varepsilon})$$

for any $\varepsilon > 0$. *Hence, the hyper-order of* f *satisfies* $\rho_2(f) \leqslant \rho$.

As for second order algebraic differential equations $\Omega(z, f, f', f'') = 0$, we first remark that the growth conjecture above has been verified for entire solutions in the homogeneous case by Steinmetz, see [176]:

THEOREM 4.7.4. *Suppose an algebraic differential equation*

$$\Omega(f, f', f'') = 0$$

is homogeneous in f, f', f'' *with polynomial coefficients. Then each meromorphic solution of such an equation takes the form* $f(z) = \frac{g_1(z)}{g_2(z)} \exp(g_3(z))$, *where* g_1, g_2, g_3 *are entire functions of finite order.*

However, the non-homogeneous case remains open in general, even for entire solutions.

Concerning algebraic differential equations of arbitrary order, there seems to be very few systematic investigations about this topic. As for differential equations of a suitable form, reasoning of Malmquist or Clunie type may sometimes help. Recalling Theorem 4.2.14, if we are considering algebraic differential equations of the form

$$\Omega(z, f, f', \ldots, f^{(n)}) = R(z, f) \tag{4.7.42}$$

with meromorphic coefficients, all of them small with respect to f, and if $\deg_f R(z, f) > \|\Omega\|$, then all possible meromorphic solutions have their growth comparable, in some sense, with the growth of the coefficients. Indeed, denoting by $\Phi(r)$ the maximum of $\log r$ and the maximum of the characteristic functions of the meromorphic coefficients of Eq. (4.7.42), then we have $T(r, f) = \mathrm{O}(\Phi(r))$, at least on a set of r-values of infinite linear measure. However, it is quite likely that such an estimate actually holds nearly everywhere. However, this has been proved in the polynomial case of $R(z, f)$ only, see [178], as far as we know.

Three natural questions concerning meromorphic solutions of algebraic differential equations (4.7.41) appear: (1) to obtain growth estimates for solutions, (2) to work out criteria under which meromorphic solutions are of finite order of growth and (3) to work criteria under which meromorphic solutions exist and if so, produce the number of meromorphic solutions, resp. the dimension of this family. The last question remains untouched here; all studies we know in this direction are restricted to first order algebraic differential equations of a special form such as $f' = P(z, f)$ with polynomial coefficients.

Concerning the growth estimates, Theorem 4.7.2 above implies that no uniform growth estimates exist in terms of the coefficients only. It appears that information about the poles and distinct zeros are needed to obtain a uniform estimate. To this end, we divide Eq. (4.7.41) in its homogeneous parts as

$$\Omega(z, f, f', \ldots, f^{(n)}) = \sum_{q=0}^{|\Omega|} \Omega_q(z, f, f', \ldots, f^{(n)}) = 0,$$

denoting by $A_q(z)$ the sum of all coefficients in the homogeneous part Ω_q. As before, we define

$$\Phi(r) := \max_{\lambda \in I}\bigl(\log r, T(r, a_\lambda)\bigr)$$

over all coefficients of P.

THEOREM 4.7.5. (See [13].) *Let f be a meromorphic solution of* (4.7.41). *If f does not satisfy some of the homogeneous equations $\Omega_q(z, f, f', \ldots, f^{(n)}) = 0$ of* (4.7.41), *then for any $\sigma > 1$, we have, for some $K > 0$,*

$$T(r, f) \leqslant K G(\sigma r)$$

for all r sufficiently large, where

$$G(r) = \overline{N}\left(r, \frac{1}{f}\right) + \overline{N}(r, f) + \Phi(r).$$

On the other hand, if f satisfies all of the homogeneous equations $\Omega_q = 0$ of (4.7.41), *while for some q, $0 \leqslant q \leqslant |\Omega|$, we have $A_q(z) \not\equiv 0$, then*

$$T(r, f) = \mathrm{O}\bigl(rN(\sigma r, f) + r^2 \exp\bigl(\mathrm{d}G(\sigma r)\log\bigl(rG(\sigma r)\bigr)\bigr)\bigr).$$

REMARKS.

(1) In principle, this enables us to determine all quantities needed to obtain a uniform growth estimate for meromorphic solutions. Indeed, if A_q vanishes in the last part of the preceding theorem, we may continue by looking at

$$\sum_{q=0}^{|\Omega|-1} \Omega_q(z, f, f', \ldots, f^{(n)}) = 0.$$

Inductively, if needed, we may proceed this way down to a first order algebraic differential equation, which always can be treated by Theorem 4.7.1.

(2) In the special case of linear differential equations, the original result has been substantially improved recently by Chiang and Hayman, see [32], p. 456. In particular, if the meromorphic solution f has a few poles only in the sense that $\delta(\infty, f) > 0$, then a uniform growth estimate follows in terms of the coefficients only.

Concerning criteria to deduce existence of finite order meromorphic solutions, only a few results are known for non-linear algebraic differential equations. We recall here the following interesting result due to Hayman, see [59]:

THEOREM 4.7.6. *Consider an algebraic differential equation* (4.7.41) *with polynomial coefficients, and denote by* Λ *the collection of terms that have maximal weight among all terms of maximal degree* $|\Omega|$. *Suppose that*

$$\sum_{\lambda\in\Lambda} a_\lambda(z) \not\equiv 0.$$

Then all entire solutions f *of* (4.7.41) *are of finite order*

$$\rho(f) \leqslant \max\bigl(2|\Omega|, 1 + |\Omega|\bigr).$$

Observe that the assertion fails for meromorphic solutions as shown by equation

$$f^2 f'' - 2f(f')^2 - f^2 f' + f'' - f' = 0,$$

where $\sum_{\lambda\in\Lambda} a_\lambda(z) = -1$, having a meromorphic solution $f(z) = \tan \mathrm{e}^z$ of infinite order.

A simple example not covered by Theorem 4.7.6 is equation

$$ff'' - (f')^2 = a_2(z)f'' + a_1(z)f' + a_0(z)f + b(z) \tag{4.7.43}$$

with rational coefficients. Hayman conjectured [59] that all entire solutions are of finite order. This has been proved in the case of constant coefficients by Chiang and Halburd [31], and considerations in [19] indicate that the conjecture might be true.

The growth of meromorphic solutions of algebraic differential equations in the unit disc still remains very much an open field of research, and some of the results obtained are too complicated to be repeated here, see e.g. [167]. Concerning first order algebraic differential equations, a unit disc counterpart to Theorem 4.7.1 has been proved by Bank in [3]:

THEOREM 4.7.7. *Consider a first order algebraic differential equation*

$$\Omega(z, f, f') = \sum_{\lambda\in I} a_\lambda(z) f^{\lambda_0} (f')^{\lambda_1} = 0$$

with analytic coefficients of finite order in the unit disc. Denote $d := \max_{\lambda\in I}\rho_M(a_\lambda)$. *Then all analytic solutions* f *of* $\Omega(z, f, f') = 0$ *in the unit disc are of finite order. More precisely,*

$$M(r, f) \leqslant \exp\bigl(\exp\bigl((1-r)^{-(d+4)}\bigr)\bigr)$$

for all $r < 1$ *close enough to* 1.

A natural problem would be to explore connections between the function spaces the solutions, resp. the coefficients of an algebraic differential equation belong to, in the same spirit as was presented for linear differential equations in Chapter 3. There are a couple of results only of this type. We quote here

THEOREM 4.7.8. *Given* $1 \leqslant \alpha < \infty$, *let* f *be a meromorphic solution of*

$$(f')^n = \sum_{j=1}^{m} P_j(z, f) D_j[f],$$

where

$$P_j(z, f) \sum_{k=0}^{m_j} a_{kj}(z) f^k, \qquad D_j[f] = (f')^{j_1} \cdots (f^{(s)})^{j_s}$$

with analytic coefficients a_{kj} *in the unit disc so that*

$$n > \nu := \max_{1\leqslant j\leqslant m} (j_1 + \cdots + s j_s).$$

If

$$\sup_{z\in\mathbb{D}}\bigl(1-|z|\bigr)^{\alpha(n-\nu)} \max_{1\leqslant j\leqslant m} \sum_{k=0}^{m_j}\bigl|a_{kj}(z)\bigr| < \infty,$$

then $f \in \mathcal{N}^\alpha$, *i.e.* f *is* α*-normal.*

Respectively, if

$$\lim_{|z|\to 1^-}\bigl(1-|z|\bigr)^{\alpha(n-\nu)} \max_{1\leqslant j\leqslant m} \sum_{k=0}^{m_j}\bigl|a_{kj}(z)\bigr| = 0,$$

then f *is strongly normal.*

4.8. *Algebraic differential equations and differential fields*

The theory of differential fields is an extensive topic which apparently has natural connections to investigations in the area of algebraic differential equations. However, these two areas have been developed rather separately of each other, and their intersection clearly is much more narrow than it could be.

To fix our notations, we restrict ourselves to considering differential fields $\mathcal{L}$ that are subfields of the field of meromorphic functions. Moreover, we steadily assume that $\mathbb{C} \subset \mathcal{L}$. Of course, results to be applied from the theory of differential fields primarily are those dealing with fields of characteristic zero. In what follows, we are considering meromorphic functions (and their subfields) in the complex plane, although some of the results apply to the unit disc case as well. Meromorphic functions that satisfy an algebraic differential equation with coefficients in $\mathcal{L}$ may be called *differentially algebraic over* $\mathcal{L}$, being denoted as $\mathcal{A}(\mathcal{L})$. It is easy to see that $\mathcal{A}(\mathcal{L})$ is a differential field. But $\mathcal{A}(\mathcal{L})$ is also closed in the sense that whenever $f \in \mathcal{A}(\mathcal{A}(\mathcal{L}))$, then $f \in \mathcal{A}(\mathcal{L})$. A meromorphic function $f \notin \mathcal{A}(\mathcal{L})$ is called *differentially transcendental over* $\mathcal{L}$. Being differential algebraic has the elementary nesting property: If $\mathcal{L} \subset \mathcal{L}_1 \subset \mathcal{L}_2$ are subfields of meromorphic functions, and if $\mathcal{L}_1 \subset \mathcal{A}(\mathcal{L})$ and $\mathcal{L}_2 \subset \mathcal{A}(\mathcal{L}_1)$, then $\mathcal{L}_2 \subset \mathcal{A}(\mathcal{L})$. Finally, we say that the differential field $\mathcal{A}(\mathbb{C})$ is the field of *differentially elementary* meromorphic functions.

Perhaps the most typical papers on the borderline of algebraic differential equations and differential fields are those proving a differentially transcendental nature of a given meromorphic function (or a certain family of meromorphic functions). This type of investigations go back to Hölder who proved (in 1887) that the gamma-function $\Gamma \notin \mathbb{C}(z)$, hence is not differentially elementary. The Hölder theorem has been improved by Bank and Kaufman in [10]. For the convenience, we denote by T_1 the translation $z \mapsto z+1$.

THEOREM 4.8.1. *Suppose* $\mathcal{L}$ *is a subfield of meromorphic functions, satisfying the following three properties*: (i) $\mathbb{C}(z) \subset \mathcal{L}$, (ii) *if* $f \in \mathcal{L}$, *then* $f \circ T_1 \in \mathcal{L}$, (iii) *if* $f \in \mathcal{L}$ *and* $f \circ T_1 - f \in \mathbb{C}(z)$, *then* $f \in \mathbb{C}(z)$. *Then the gamma-function* Γ *is differentially transcendental over* $\mathcal{L}$, *hence over* $\mathcal{A}(\mathcal{L})$ *as well. In particular,* Γ *is differentially transcendental over the field of meromorphic functions* f *that satisfy* $T(r, f) = o(r)$.

For a simple proof of the following result, see [127]:

THEOREM 4.8.2. *The Riemann zeta-function* ζ *is not differentially elementary.*

A natural extension of the notion of algebraic independence may be applied to define *differential independence* of meromorphic functions. In particular, if f, g are two meromorphic functions, they are said to differentially independent (over $\mathbb{C}$), if either f is differentially transcendental over $\mathbb{C}(g)$, or g is differentially transcendental over $\mathbb{C}(f)$.

THEOREM 4.8.3. (*See [127].*) *The following pairs of meromorphic functions are differentially independent over* $\mathbb{C}$:

(1) $\Gamma(\sin(2\pi z))$ *and* $\Gamma(z)$;

(2) $\zeta(\sin(2\pi z))$ *and* $\Gamma(z)$.

REMARK. A natural conjecture would be that $\zeta(z)$ and $\Gamma(z)$ are differentially independent over $\mathbb{C}$, not the least due to Theorem 4.8.3(2). However, this remains an open problem.

Another group of results in the borderline area of algebraic differential equations and differential fields are related to the following classical lemma, see [107], Lemma 14.3.1, originally due to Siegel. We remark that this lemma is part of the bridge between complex differential equations and transcendental number theory, again a borderline area, which apparently needs more exploration.

THEOREM 4.8.4. *Consider a second-order linear differential equation*

$$f'' + a(z)f' + b(z)f = 0 \tag{4.8.44}$$

over a subfield $\mathcal{L}$ of meromorphic functions. Suppose (4.8.44) *admits a solution f_0 that is* (*algebraically*) *transcendental over $\mathcal{L}$, but satisfies a first-order algebraic differential equation over $\mathcal{L}$. Then there exists another non-trivial solution f of* (4.8.44) *such that f'/f is algebraic over $\mathcal{L}$.*

Example of a consequence of the Siegel lemma is concerned with the basic linear differential equation $f'' + A(z)f = 0$, where $A(z)$ is a non-constant polynomial of degree n. Denoting by $\mathcal{L}_{(n+2)/2}$ the differential field of meromorphic functions of order $< (n+2)/2$, we get

THEOREM 4.8.5. *If n is odd, then no non-trivial solution of $f'' + A(z)f = 0$ with a polynomial $A(z)$ of degree n can satisfy a first-order algebraic differential equations over $\mathcal{L}_{(n+2)/2}$. On the other hand, if n is even, then at least one of any two linearly independent solutions of $f'' + A(z)f = 0$ cannot satisfy a first-order algebraic differential equation over $\mathcal{L}_{(n+2)/2}$.*

For further results of similar type, see [4,5].

5. Algebroid solutions of complex differential equations

5.1. *Introduction to algebroid functions*

Algebroid functions in the complex plane are formed by collections of analytic function elements that satisfy an irreducible algebraic equation

$$A_n(z)f^n + A_{n-1}(z)f^{n-1} + \cdots + A_1(z)f + A_0(z) = 0 \tag{5.1.1}$$

with meromorphic coefficients. This means that the collection of algebroid functions in the complex plane form an extension field of the field of meromorphic functions. Moreover, an algebroid function f as defined above is n-valued, hence f may be understood as a one-valued meromorphic function on an n-sheeted Riemann surface. Typical examples of elementary algebroid functions are nth roots of meromorphic functions. In many aspects, algebroid functions behave similarly as to meromorphic functions. However, there are fundamental differences such as, for example, the phenomenon that the derivative f' of an algebroid function may have a pole at a point where the function f itself takes a finite value. A simple example is $\sqrt{z}$ whose derivative $1/(2\sqrt{z})$ has a pole at the origin. Of course, the branch points of f also add an aspect which has no direct counterpart in the realm of meromorphic functions.

Nevanlinna theory of meromorphic functions has a natural extension to algebroid functions, soon developed in early 1930's, most notably by Valiron [184], Selberg [153] and Ullrich [183]. Since Nevanlinna theory is a powerful tool to investigating algebroid solutions of complex differential equations, we shortly describe some of its similarities and deviations as compared to the original meromorphic version.

Let f be a non-constant ν-valued algebroid function, that has at z_0 an a-point, resp. a pole, with local expansions about z_0 of the form

$$f(z) = a + b_\tau (z - z_0)^{\tau/\lambda} + \cdots, \quad \tau \geqslant 1, \tag{5.1.2}$$

resp.

$$f(z) = b_{-\tau} (z - z_0)^{-\tau/\lambda} + \cdots, \quad \tau \geqslant 1, \tag{5.1.3}$$

where $\lambda \leqslant \nu$. The *non-integrated counting function* $n(r, 1/(f-a))$ for the a-points, resp. $n(r, f)$ for the poles in the disc $|z| \leqslant r$, is the sum of the τ's in the preceding expansions, over all a-points, resp. over all poles, in $|z| \leqslant r$. The *integrated counting function* is now defined as in the usual meromorphic theory, taking however into account the fact that we are now operating on an ν-sheeted surface S_f over the disc $|z| \leqslant r$, i.e.,

$$N\left(r, \frac{1}{f-a}\right) := \frac{1}{\nu} \int_0^r \frac{n(t,a) - n(0,a)}{t}\, \mathrm{d}t + \frac{1}{\nu} n(0,a) \log r,$$

resp.

$$N(r, f) := \frac{1}{\nu} \int_0^r \frac{n(t,f) - n(0,f)}{t}\, \mathrm{d}t + \frac{1}{\nu} n(0,f) \log r.$$

Similarly, we define the *proximity function* as

$$m\left(r, \frac{1}{f-a}\right) := \frac{1}{\nu} \sum_{j=1}^{\nu} \frac{1}{2\pi} \int_0^{2\pi} \log^+ \frac{1}{|f_j(r\mathrm{e}^{\mathrm{i}\theta}) - a|}\, \mathrm{d}\theta,$$

resp.

$$m(r, f) := \frac{1}{\nu} \sum_{j=1}^{\nu} \frac{1}{2\pi} \int_0^{2\pi} \log^+ \left| f_j(r\mathrm{e}^{\mathrm{i}\theta}) \right| \mathrm{d}\theta,$$

where f_j stands for the values of f on the jth sheet of the surface S_f. The *characteristic function* $T(r, f) := m(r, f) + N(r, f)$ is now defined as usual, and the first main theorem takes its usual form $T(r, 1/(f-a)) = T(r, f) + \mathrm{O}(1)$. Moreover, an algebroid function f is algebraic if and only if $T(r, f) = \mathrm{O}(\log r)$, and the lemma of the logarithmic derivative takes its usual form $m(r, f^{(k)}/f) = S(r, f)$, $k \in \mathbb{N}$, in general and $m(r, f^{(k)}/f) = \mathrm{O}(\log r)$ for an algebroid function of finite order.

The key deviation from the usual meromorphic theory comes out of the *counting function of branch points* of f, which may be determined from the expansions (5.1.2), (5.1.3) as

$$n_3(r, f) := \sum_{|z| \leqslant r,\, a \in \widehat{\mathbb{C}}} (\lambda - 1)$$

first in the non-integrated form, and then the integrated counting function of branch points $N_3(r, f)$ follows exactly as above for $N(r, f)$, say. We also make use of the corresponding function $N_{3,\infty}(r, f)$ for branched poles above the disc $|z| \leqslant r$. The essential consequences may now be expressed as

PROPOSITION 5.1.1. *Let f be a ν-valued algebroid function. Then*
(1) $N_3(r, f) \leqslant 2(\nu - 1)T(r, f) + \mathrm{O}(1)$
and
(2) $T(r, f') \leqslant 2T(r, f) + N_3(r, f) + S(r, f) \leqslant 2\nu T(r, f) + S(r, f)$.

For more details and proofs concerning the basic Nevanlinna theory of algebroid functions, see [184,153,183] and [100].

We next give the algebroid versions of the Clunie, Mohon'ko and Valiron–Mohon'ko lemmas, see Section 4.1 for the corresponding meromorphic versions:

THEOREM 5.1.2. *Let f be an algebroid solution of*

$$f^n P(z, f) = Q(z, f),$$

where $P(z, f)$, $Q(z, f)$ are polynomials in f and its derivatives with algebroid coefficients, say a_λ, $\lambda \in I$, such that $m(r, a_\lambda) = S(r, f)$ for all $\lambda \in I$. If the total degree of $Q(z, f)$ in f and its derivatives is $\leqslant n$, then

$$m\bigl(r, P(z, f)\bigr) = S(r, f).$$

REMARK. The standard proof of the meromorphic version applies here. One just needs to replace the notions from meromorphic value distribution theory with the corresponding algebroid ones. The key point is that the logarithmic derivative lemma applies in the same form as in the meromorphic case.

THEOREM 5.1.3. (See [128].) *Let f be a meromorphic solution of an algebraic differential equation*

$$P(z, f, f', \ldots, f^{(n)}) = 0, \tag{5.1.4}$$

where P is a polynomial in $f, f', \dots, f^{(n)}$ with meromorphic coefficients small with respect to f. If a complex constant c does not satisfy Eq. (5.1.4), *then*

$$m\left(r, \frac{1}{f-c}\right) = S(r, f).$$

THEOREM 5.1.4. (See [128,129].) *Let f be an algebroid function, and let $R(z, f) = P(z, f)/Q(z, f)$ be an irreducible rational function in f with algebroid coefficients small with respect to f. Then the characteristic function of $R(z, f(z))$ satisfies*

$$T\big(r, R(z, f)\big) = dT(r, f) + S(r, f),$$

where $d := \max(\deg_f P(z, f), \deg_f Q(z, f))$.

5.2. *Malmquist type theorems for algebroid functions*

We start by giving the algebroid counterpart of Theorem 4.2.2:

THEOREM 5.2.1. *If a differential equation of the form*

$$(f')^n = R(z, f), \tag{5.2.5}$$

where $R(z, f) = P(z, f)/Q(z, f)$ is rational and irreducible in f with meromorphic coefficients, admits a ν-valued algebroid solution f such that all coefficients of $R(z, f)$ are small with respect to f, then

$$q := \deg Q \leqslant 2n(\nu - 1), \qquad p := \deg P \leqslant q + 2n \leqslant 2n\nu.$$

REMARKS.

(1) This result was originally proved by Yosida [194]. He also proved that all algebroid solutions of (5.2.5) with small meromorphic coefficients are of finite order of growth, see [194], Theorem 7.

(2) As a deviation from the meromorphic case, observe that $R(z, f)$ does not necessarily reduce to a polynomial in f as shown by an example in [45]: The equation $f^2 + f \tan z + z = 0$ defines a two-valued algebroid function that satisfies

$$f' = \frac{z^2 + f + (1 + 2z)f^2 + f^4}{z - f^2}.$$

However, if the solution has not too much of the branch points, then $R(z, f)$ reduces to polynomial:

THEOREM 5.2.2. (See [100].) *Under the same assumptions as in Theorem* 5.2.1, *if*

$$\xi(f) := \limsup_{r\to\infty} \frac{N_3(r, f)}{T(r, f)} < \frac{1}{n},$$

then $R(z, f)$ reduces to a polynomial in f of degree $\leqslant 2n$.

REMARKS.

(1) The assumption that $\xi(f) < 1/n$ cannot be improved, as shown in [145], Beispiel 7.1: Consider $f(z) := (e^z - 1)^{-1}$, and define algebroid functions w, v by the algebraic equation $w^2 - f(z) = 0$ and $v := (w-1)^{-1}$. Then v satisfies

$$v' = -\frac{(v+1)(2v^2+2v+1)}{2v},$$

while $\xi(v) = 1$.

(2) In the case of Theorem 5.2.2, the reduction may still be continued further in the algebroid case similarly as in the meromorphic case, see [100], Theorem 3.10 and [145], Satz 7.3.

(3) Concerning some introductory remarks of the value distribution of algebroid solutions of (5.2.5) with small meromorphic coefficients, see [145], Section 8.

(4) The Malmquist type theorems above for algebroid solutions correspond to Theorem 4.2.2 for meromorphic solutions. Concerning a counterpart of Theorem 4.2.7 for the algebroid case, see [39], [86], Satz 4.5 and [128], Theorem 5.

5.3. *Algebroid solutions of algebraic differential equations*

Investigations concerning algebroid solutions of algebraic differential equations

$$\Omega(z, f, f', \ldots, f^{(n)}) = 0, \tag{5.3.6}$$

where Ω is a polynomial in the variables $f, f', \ldots, f^{(n)}$ with meromorphic coefficients, are quite few, although this could also be an extensive field of research.

In considering an expression such as

$$\Omega(z, f, f', \ldots, f^{(n)}) = \sum_{\lambda \in I} a_\lambda(z) f^{\lambda_0} \cdots (f^{(n)})^{\lambda_n},$$

we apply the same notations concerning degree and weight as in Section 4.7, i.e.

$$|\Omega| := \max_{\lambda \in I} |\lambda|, \qquad \|\Omega\| := \max_{\lambda \in I} \|\lambda\|.$$

In addition, we need a couple of notations for certain modified versions of the weight:

$$|\Omega|_0 := \max_{\lambda \in I} \sum_{j=1}^{n} j\lambda_j, \qquad |\Omega|_1 := \max_{\lambda \in I} \sum_{j=1}^{n} (2j-1)\lambda_j.$$

Similarly as in the meromorphic case, see Theorem 4.2.14, Theorem 5.2.1 may be extended to algebraic differential equations of the form

$$\Omega(z, f, f', \dots, f^{(n)}) = R(z, f) = \frac{P(z, f)}{Q(z, f)}, \tag{5.3.7}$$

where $P(z, f)$, $Q(z, f)$ are polynomials in f with meromorphic coefficients, and $\Omega(z, f, f', \dots, f^{(n)})$ is a differential polynomial in f with meromorphic coefficients. Making use of the notations above for degree, weight etc. of Ω, and denoting $p := \deg P$, $q := \deg Q$, we get the following

THEOREM 5.3.1. (See [181].) *Suppose f is a ν-valued algebroid solution of Eq.* (5.3.7) *with small meromorphic coefficients. Then we have*

$$\max\bigl(p, q + \|\Omega\|\bigr) \leqslant \|\Omega\| + |\Omega|_1 \xi(f),$$
$$p \leqslant \min\bigl(q + |\Omega| + |\Omega|_0\bigl(1 - \Theta(\infty, f) + \xi_\infty(f)\bigr), \|\Omega\| + |\Omega|_1 \xi(f)\bigr),$$

where $\xi_\infty(f) := \limsup_{r\to\infty} \frac{N_{3,\infty}(r, f)}{T(r, f)}$.

REMARK.

(1) For several closely related variants of Theorem 5.3.1, see [48] and [47].

(2) As in the model case of Theorem 5.2.1, the reduced form may have a non-trivial denominator, contrary to the meromorphic case, see Theorem 4.2.14. However, if $\xi(f) = 0$, then the denominator becomes trivial, and we have

COROLLARY 5.3.2. *If* $\xi(f) = 0$, *then*

$$q = 0, \qquad p \leqslant \min\bigl(\|\Omega\|, |\Omega| + |\Omega|_0\bigl(1 - \Theta(\infty, f)\bigr)\bigr).$$

REMARK. Several of the items in the list of references below contain some additional results concerning algebroid solutions of algebraic differential equations. In particular, we refer to [39] and [86], Section 4. See also [179,180].

5.4. *Algebroid solutions of linear differential equations*

The only paper we know investigating algebroid solutions of linear differential equations of type

$$f'' + A(z) f = 0,$$

where $A(z)$ is meromorphic, is due to Katajamäki, see [100], Section 5. We quote here a couple of his results, THEOREM 5.4.1. *If the quotient of two local solutions of the equation* $f'' + A(z)f = 0$ *admits in a disc, where* $A(z)$ *is holomorphic, a* ν*-valued,* $\nu \geqslant 2$*, algebroid continuation into the complex plane, then at each pole* z_0 *of* $A(z)$ *either* (1) *the Laurent expansion of* $A(z)$ *about* z_0 *has the form*

$$A(z) = \frac{1 - m^2}{4(z - z_0)^2} + \cdots ,$$

where $m = p/q$ *is rational but not an integer,* p, q *have no non-trivial common factors, and* $q|\nu$*, or* (2) m *is an integer* $\geqslant 2$ *and the determinant condition* $D(z_0) = 0$ *in* (2.4.25) *holds.*

This theorem now has the following consequence:

THEOREM 5.4.2. *If equation* $f'' + A(z)f = 0$ *admits a* ν*-valued,* $\nu \geqslant 2$*, algebroid solution in the complex plane, then the equation has no non-trivial meromorphic solutions.*

THEOREM 5.4.3. *If equation* $f'' + A(z)f = 0$ *admits a* 2*-valued algebroid solution* f *in the complex plane, then* f *must be a square-root of a meromorphic function, i.e.* f^2 *is meromorphic.*

As for algebroid solutions of linear differential equations of higher order, see Tohge [182].

Acknowledgement

My best gratitude is due to all of my friends and colleagues who have had a role in the preparation of this survey, either directly or indirectly. Special thanks are due to my junior colleagues, Janne Heittokangas and Risto Korhonen. Of course, the final survey reflects my personal opinion of the field, and all possible defects, mistakes and misunderstandings are on my responsibility. In any case, I hope that this survey might serve as a completion to previous key references in the field, assisting beginners to penetrate in the wealth of material available.

1. Introduction

The possible presence of transversal homoclinic points and the complicated dynamics associated with them was noticed by Poincaré [21] while studying the restricted three-body problem. Later Birkhoff [3] proved that every transversal homoclinic point of a two-dimensional diffeomorphism is accumulated by periodic points. Then Smale's [25] theorem showed that the existence of a transversal homoclinic orbit implied the presence of a horseshoe, and hence complicated dynamics.

Note that Smale's result was proved for diffeomorphisms. A transversal homoclinic point is a point where the stable and unstable manifolds of a hyperbolic fixed point intersect transversally. The corresponding notion for a flow is a point where the stable and unstable manifolds of a hyperbolic periodic orbit intersect transversally. We call the orbit of such a point a transversal periodic-to-periodic homoclinic orbit, the subject of the present chapter. Sil'nikov [22] proved a result analogous to Smale's for transversal periodic-to-periodic homoclinic orbits. A detailed history of homoclinic orbits is given by Sil'nikov [23].

A homoclinic orbit of a diffeomorphism is transversal if and only if the invariant set consisting of it and the associated hyperbolic fixed point is hyperbolic (confer [19]). This, in turn, happens if and only if the variational equation along the homoclinic orbit has an exponential dichotomy. Analogously a periodic-to-periodic homoclinic orbit of a flow is transversal if and only if the invariant set consisting of it and the associated hyperbolic periodic orbit is hyperbolic. It turns out that happens if and only if the variational equation along the homoclinic orbit has what we call a trichotomy. Trichotomy is similar to an exponential dichotomy but with the difference that there is an additional one-dimensional subspace of bounded solutions. Trichotomies play an important role in our development of the theory and so Section 2 is devoted to their study.

In Section 3 we first define the Poincaré map associated with a periodic orbit of an autonomous system of ordinary differential equations. Then we construct the local and global stable and unstable manifolds of a hyperbolic periodic orbit, thereby introducing the concept of asymptotic phase. These, of course, are well-known results but we give detailed proofs because, for later application, we need the results in a special form. Note that our smoothness assumptions may not be optimal.

In Section 4 we study properties of periodic-to-periodic homoclinic orbits. First we define a Poincaré map associated with such an orbit similar to that given by Hale and Lin in [11]. Then we give equivalent conditions for transversality of the periodic-to-periodic homoclinic orbits including its equivalence with the transversality of the corresponding homoclinic orbit of the Poincaré map. Note that the possibility of doing this was suggested to me in a conversation with Daniel Stoffer in Santander airport. Then Smale's theorem enables to deduce the existence of chaotic behaviour in the neighbourhood of a transversal periodic-to-periodic homoclinic orbit. Note that in [19] a shadowing theorem for hyperbolic sets of flows was used to give a complete symbolic description of the dynamics in the neighbourhood of a transversal periodic-to-periodic homoclinic orbit.

In Section 5 we consider an autonomous system depending on a parameter where we assume the unperturbed system has a hyperbolic periodic orbit with associated transversal homoclinic orbit. We show that the perturbed system has a similar structure.

Even though, as we found in Section 5, transversal periodic-to-periodic homoclinic orbits persist under perturbation, it does not seem possible to write down an explicit system with an explicit transversal periodic-to-periodic homoclinic orbit. This is also the situation with homoclinic points of diffeomorphisms. In the latter case, Melnikov [15] finds diffeomorphisms with transversal homoclinic points as period maps of differential equations with time-periodic vector fields which are perturbations of autonomous systems with nontransversal homoclinic orbits. In Section 6 we prove an analogous theorem for periodic-to-periodic homoclinic orbits of flows. We begin with a system with a nontransversal homoclinic orbit; such systems can be easily written down explicitly. Then we show that a perturbed system has a transversal orbit nearby provided a certain Melnikov function has a simple zero. Note that the existence of transversal periodic-to-periodic homoclinic orbits in singularly perturbed systems has been shown by Szmolyan in [26]; see also [1]. Note also that in [7] Deng and Sakamoto show that periodic-to-periodic homoclinic orbits arise as the result of a Sil'nikov–Hopf bifurcation. However, these orbits may be nontransversal.

In Section 7, which is based on Coomes, Koçak and Palmer [4], it is shown how transversal periodic-to-periodic homoclinic orbits can be constructed via numerical shadowing. We begin with a numerically computed orbit which appears to be bi-asymptotic to an also numerically computed apparent periodic orbit. The main theorem gives computable criteria for verifying the existence of a true periodic orbit and an associated true transversal homoclinic orbit near the numerically computed orbits. Other authors, for example, Dieci and Rebaza [9] and Pampel [20], inspired by the work of Beyn [2], approximate a connecting orbit by the solution of a certain boundary value problem and they derive estimates for the error in the approximation. However, these works are carried out on the assumption that a true connecting orbit exists. Examples of transversal periodic-to-periodic homoclinic in the restricted three-body problem are studied in Kirchgraber and Stoffer [14].

2. Trichotomies

It turns out that a periodic-to-periodic homoclinic orbit is transversal if and only if its variational equation has a trichotomy in the sense defined below. So trichotomies are an important tool in our study and, in this section, we prove the results about trichotomies that we will need in the sequel.

DEFINITION 2.1. Let $A(t)$ be a continuous $n \times n$ matrix function. The linear system

$$\dot{x} = A(t)x \tag{1}$$

is said to have a *trichotomy* on an interval J if there exist supplementary projections P_0, P_+, P_- with rank $P_0 = 1$ and positive constants K, α such that

$$\begin{aligned} &\left|X(t)P_0X^{-1}(s)\right| \leqslant K \quad \text{for all } t, s,\\ &\left|X(t)P_+X^{-1}(s)\right| \leqslant K\mathrm{e}^{-\alpha(t-s)} \quad \text{for } t \geqslant s,\\ &\left|X(t)P_-X^{-1}(s)\right| \leqslant K\mathrm{e}^{-\alpha(s-t)} \quad \text{for } t \leqslant s \end{aligned} \tag{2}$$

where $X(t)$ is the fundamental matrix for (1) with $X(0) = I$.

Note that if $P_0 = 0$ we have an exponential dichotomy. Sometimes we refer to K as the “constant” and to α as the “exponent”.

Trichotomies have similar properties to exponential dichotomies. We describe these properties in the remarks below.

REMARK 2.2. *Characterization of projections*. If $J = [t_0, \infty)$, then it is clear that

$$\begin{aligned}
\mathcal{R}(P_+) &= \bigl\{\xi\colon \bigl|X(t)\xi\bigr| \to 0 \text{ as } t \to \infty\bigr\},\\
\mathcal{R}(P_0 + P_+) &= \Bigl\{\xi\colon \sup_{t \geqslant t_0}\bigl|X(t)\xi\bigr| < \infty\Bigr\}.
\end{aligned}$$

Now we show that $\mathcal{R}(P_0)$ can be any complementary subspace U_0 to $\mathcal{R}(P_+)$ in $\mathcal{R}(P_0 + P_+)$ and that $\mathcal{R}(P_-)$ can be any complementary subspace W_0 to $\mathcal{R}(P_0 + P_+)$ in $\mathbf{R}^n$. To see this, let Q_0, Q_+ and Q_- be the projections associated with the splitting

$$\mathbf{R}^n = U_0 \oplus \mathcal{R}(P_+) \oplus W_0.$$

Then for $t, s \geqslant t_0$, since $\mathcal{R}(P_+) = \mathcal{R}(Q_+)$ so that $P_+Q_+ = Q_+$ and $Q_+P_+ = P_+$,

$$\begin{aligned}
&\bigl|X(t)(Q_+ - P_+)X^{-1}(s)\bigr|\\
&\quad = \bigl|X(t)P_+(Q_+ - P_+)(I - P_+)X^{-1}(s)\bigr|\\
&\quad \leqslant \bigl|X(t)P_+X^{-1}(t_0)\bigr|\bigl|X(t_0)(Q_+ - P_+)X^{-1}(t_0)\bigr|\bigl|X(t_0)(P_0 + P_-)X^{-1}(s)\bigr|\\
&\quad \leqslant K\mathrm{e}^{-\alpha(t-t_0)}\bigl|X(t_0)(Q_+ - P_+)X^{-1}(t_0)\bigr|2K\\
&\quad = 2K^2\bigl|X(t_0)(Q_+ - P_+)X^{-1}(t_0)\bigr|\mathrm{e}^{-\alpha(t-t_0)}\\
&\quad = K_1\mathrm{e}^{-\alpha(t-t_0)}
\end{aligned}$$

and since $\mathcal{N}(P_-) = \mathcal{N}(Q_-)$ so that $P_-Q_- = P_-$ and $Q_-P_- = Q_-$,

$$\begin{aligned}
&\bigl|X(t)(Q_- - P_-)X^{-1}(s)\bigr|\\
&\quad = \bigl|X(t)(P_0 + P_+)(Q_- - P_-)P_-X^{-1}(s)\bigr|\\
&\quad \leqslant \bigl|X(t)(P_0 + P_+)X^{-1}(t_0)\bigr|\bigl|X(t_0)(Q_- - P_-)X^{-1}(t_0)\bigr|\bigl|X(t_0)P_-X^{-1}(s)\bigr|\\
&\quad \leqslant 2K\bigl|X(t_0)(Q_- - P_-)X^{-1}(t_0)\bigr|K\mathrm{e}^{-\alpha(s-t_0)}\\
&\quad = K_2\mathrm{e}^{-\alpha(s-t_0)}.
\end{aligned}$$

In particular this implies that if $t \geqslant t_0$,

$$\bigl|X(t)(Q_+ - P_+)X^{-1}(t)\bigr| \leqslant K_1, \qquad \bigl|X(t)(Q_- - P_-)X^{-1}(t)\bigr| \leqslant K_2.$$

Then going through the first argument again with t_0 replaced by s, with $s \geqslant t_0$, we find that for $t \geqslant s \geqslant t_0$

$$\left|X(t)(Q_+ - P_+)X^{-1}(s)\right| \leqslant K_3 \mathrm{e}^{-\alpha(t-s)},$$

where $K_3 = 2K^2K_1$, and going through the second argument again with t_0 replaced by t, with $t \geqslant t_0$, we find that for $s \geqslant t \geqslant t_0$

$$\left|X(t)(Q_- - P_-)X^{-1}(s)\right| \leqslant K_4 \mathrm{e}^{-\alpha(s-t)},$$

where $K_4 = 2K^2K_2$. Also we note that for $t, s \geqslant t_0$

$$\begin{aligned}\left|X(t)(Q_0 - P_0)X^{-1}(s)\right| &\leqslant \left|X(t)(Q_+ - P_+)X^{-1}(s)\right| \\ &\quad + \left|X(t)(Q_- - P_-)X^{-1}(s)\right| \\ &\leqslant K_1 + K_2.\end{aligned}$$

Then we see that for $t, s \geqslant t_0$

$$\begin{aligned}\left|X(t)Q_0X^{-1}(s)\right| &\leqslant \left|X(t)P_0X^{-1}(s)\right| + \left|X(t)(Q_0 - P_0)X^{-1}(s)\right| \\ &\leqslant K + K_1 + K_2,\end{aligned}$$

for $t \geqslant s \geqslant t_0$

$$\begin{aligned}\left|X(t)Q_+X^{-1}(s)\right| &\leqslant \left|X(t)P_+X^{-1}(s)\right| + \left|X(t)(Q_+ - P_+)X^{-1}(s)\right| \\ &\leqslant (K + K_3)\mathrm{e}^{-\alpha(t-s)}\end{aligned}$$

and for $s \geqslant t \geqslant t_0$

$$\begin{aligned}\left|X(t)Q_-X^{-1}(s)\right| &\leqslant \left|X(t)P_-X^{-1}(s)\right| + \left|X(t)(Q_- - P_-)X^{-1}(s)\right| \\ &\leqslant (K + K_4)\mathrm{e}^{-\alpha(s-t)}.\end{aligned}$$

If $J = (-\infty, t_0]$, then it is clear that

$$\begin{aligned}\mathcal{R}(P_-) &= \left\{\xi\colon \left|X(t)\xi\right| \to 0 \text{ as } t \to -\infty\right\}, \\ \mathcal{R}(P_0 + P_-) &= \left\{\xi\colon \sup_{t \leqslant t_0}\left|X(t)\xi\right| < \infty\right\},\end{aligned}$$

and we can similarly prove that $\mathcal{R}(P_0)$ can be any complementary subspace to $\mathcal{R}(P_-)$ in $\mathcal{R}(P_0 + P_-)$ and that $\mathcal{R}(P_+)$ can be any complementary subspace to $\mathcal{R}(P_0 + P_-)$ in $\mathbf{R}^n$.

If $J = \mathbf{R}$, it is clear that

$$\begin{aligned}\mathcal{R}(P_+) &= \left\{\xi\colon \left|X(t)\xi\right| \to 0 \text{ as } t \to \infty\right\}, \\ \mathcal{R}(P_-) &= \left\{\xi\colon \left|X(t)\xi\right| \to 0 \text{ as } t \to -\infty\right\},\end{aligned}$$

and

$$\mathcal{R}(P_0) = \Big\{\xi\colon \sup_{t\in\mathbf{R}}\big|X(t)\xi\big| < \infty\Big\}.$$

So, in this case, up to a scalar multiple, the linear system has a unique nontrivial bounded solution $x_0(t)$ where $x_0(0)$ spans the range of P_0 and, moreover, $\inf_{t\in\mathbf{R}} |x_0(t)| \geqslant K^{-1}|x_0(0)| > 0$.

REMARK 2.3. *If* $t_0 < t_1$, *trichotomy on* $[t_1, \infty)$ *implies trichotomy on* $[t_0, \infty)$. Let (1) have a trichotomy on $[t_1, \infty)$ as in Definition 2.1. For $\sigma = 0, +, -$, define

$$M_\sigma = \sup\big\{\mathrm{e}^{\alpha(t-s)}\big|X(t)P_\sigma X^{-1}(s)\big|\colon\ t_0 \leqslant t, s \leqslant t_1\big\}.$$

Then for $t_0 \leqslant t, s \leqslant t_1$ and $\sigma = 0, +, -$,

$$\big|X(t)P_\sigma X^{-1}(s)\big| \leqslant M_\sigma \mathrm{e}^{-\alpha(t-s)}.$$

Then, for example, if $t_0 \leqslant s \leqslant t_1 \leqslant t$,

$$\big|X(t)P_+X^{-1}(s)\big| \leqslant \big|X(t)P_+X^{-1}(t_1)\big|\big|X(t_1)P_+X^{-1}(s)\big| \leqslant M_+K\mathrm{e}^{-\alpha(t-s)}.$$

It follows that if $t_0 \leqslant s \leqslant t$,

$$\big|X(t)P_+X^{-1}(s)\big| \leqslant K_1\mathrm{e}^{-\alpha(t-s)},$$

where

$$K_1 = \max\{K, M_+K\}.$$

The inequalities for P_0 and P_- can be similarly derived.

Similarly, if $t_0 > t_1$, trichotomy on $(-\infty, t_1]$ implies trichotomy on $(-\infty, t_0]$.

REMARK 2.4. *Trichotomy on* $\mathbf{R}$ *from trichotomies on* $\mathbf{R}_+$ *and* $\mathbf{R}_-$. If (1) has a trichotomy on $\mathbf{R}$, then it certainly has trichotomies on $\mathbf{R}_+$ and $\mathbf{R}_-$ with projections of the same rank and, as we saw at the end of Remark 2.2, (1) has, up to a scalar multiple, a unique nontrivial bounded solution $x_0(t)$ which also satisfies $\inf_{t\in\mathbf{R}} |x_0(t)| > 0$.

The converse statement is also true. Suppose the projections on $[0, \infty)$ are P_0, P_+, P_- and the projections on $(-\infty, 0]$ are Q_0, Q_+, Q_- with K and α as the constants in both cases. Now if $\xi \in \mathcal{R}(P_+) \cap \mathcal{R}(Q_0 + Q_-)$, then $X(t)\xi$ is bounded on the whole line and hence is a multiple of $x_0(t)$. However, $X(t)\xi \to 0$ as $t \to \infty$ and so $\xi = 0$. Hence $\mathcal{R}(P_+)$ is complementary to $\mathcal{R}(Q_0 + Q_-)$ and so, by Remark 2.2, the Q_σ can be chosen so that $\mathcal{R}(Q_+) = \mathcal{R}(P_+)$. Similarly, we can assume $\mathcal{R}(P_-) = \mathcal{R}(Q_-)$. Next since $\inf_{t\in\mathbf{R}} |x_0(t)| > 0$, $\operatorname{span}\{x_0(0)\}$ is complementary to $\mathcal{R}(P_+)$ in $\mathcal{R}(P_0 + P_+)$ and also complementary to

$\mathcal{R}(Q_-)$ in $\mathcal{R}(Q_0 + Q_-)$. Hence we can assume $\mathcal{R}(P_0) = \mathcal{R}(Q_0) = \operatorname{span}\{x_0(0)\}$. Thus we can arrange that $P_\sigma = Q_\sigma$ for $\sigma = 0, +, -$. Then we know that

$$\left|X(t)P_+X^{-1}(s)\right| \leqslant K\mathrm{e}^{-\alpha(t-s)}$$

for $s \leqslant t \leqslant 0$ and $0 \leqslant s \leqslant t$. If $s \leqslant 0 \leqslant t$, then

$$\begin{aligned}\left|X(t)P_+X^{-1}(s)\right| &\leqslant \left|X(t)P_+X^{-1}(0)\right|\left|X(0)P_+X^{-1}(s)\right| \\ &\leqslant K\mathrm{e}^{-\alpha t}K\mathrm{e}^{-\alpha(0-s)} \\ &= K^2\mathrm{e}^{-\alpha(t-s)}.\end{aligned}$$

Using two more similar arguments, we see that (1) has a trichotomy on **R** with constants K^2 and α.

REMARK 2.5. *The case when $A(t)$ is bounded.* If $A(t)$ is bounded, we can weaken the inequalities in the definition of trichotomy to having for all ξ

$$\begin{aligned}&\left|X(t)P_0\xi\right| \leqslant K\left|X(s)P_0\xi\right| \quad \text{for all } t, s,\\ &\left|X(t)P_+\xi\right| \leqslant K\mathrm{e}^{-\alpha(t-s)}\left|X(s)P_+\xi\right| \quad \text{for } t \geqslant s,\\ &\left|X(t)P_-\xi\right| \leqslant K\mathrm{e}^{-\alpha(s-t)}\left|X(s)P_-\xi\right| \quad \text{for } t \leqslant s\end{aligned}$$

since these inequalities imply that for $t \geqslant s$

$$\frac{|X(t)P_+\xi||X(s)P_0\xi|}{|X(s)P_+\xi||X(t)P_0\xi|} \leqslant K^2\mathrm{e}^{-\alpha(t-s)}$$

and

$$\frac{|X(t)P_0\xi||X(s)P_-\xi|}{|X(s)P_0\xi||X(t)P_-\xi|} \leqslant K^2\mathrm{e}^{-\alpha(t-s)}.$$

This means the solution subspaces corresponding to P_+, P_0 and P_- are exponentially separated and so by Lemma 1 in [16] the norms of the projections $X(t)P_\sigma X^{-1}(t)$ are bounded by a constant M (say) and so, for example, if $s \leqslant t$ then for all ξ

$$\left|X(t)P_+X^{-1}(s)\xi\right| \leqslant K\mathrm{e}^{-\alpha(t-s)}\left|X(s)P_+X^{-1}(s)\xi\right| \leqslant KM\mathrm{e}^{-\alpha(t-s)}|\xi|$$

so that

$$\left|X(t)P_+X^{-1}(s)\right| \leqslant KM\mathrm{e}^{-\alpha(t-s)}.$$

REMARK 2.6. *The adjoint equation*. By taking adjoints in the inequalities (2) and exchanging s and t, we find that

$$\begin{aligned} &\left|Y(t)P_0^*Y^{-1}(s)\right| \leqslant K \quad \text{for all } t, s, \\ &\left|Y(t)P_-^*Y^{-1}(s)\right| \leqslant K\mathrm{e}^{-\alpha(t-s)} \quad \text{for } t \geqslant s, \\ &\left|Y(t)P_+^*X^{-1}(s)\right| \leqslant K\mathrm{e}^{-\alpha(s-t)} \quad \text{for } t \leqslant s, \end{aligned}$$

where $Y(t) = X^{-1}(t)^*$. So the adjoint system has a trichotomy on J with projections P_0^*, P_-^*, P_+^*.

REMARK 2.7. *Roughness theorem*. For this, for convenience, we restrict to the case where J is $\mathbf{R}$, $\mathbf{R}_+$ or $\mathbf{R}_-$. We show the following result.

Suppose (1) *has a trichotomy as in Definition* 2.1, *letting* $x_0(t)$ *be the solution with* $P_0x_0(0) = x_0(0)$ *and* $|x_0(0)| = 1$. *Let* $B(t)$ *be a continuous matrix function with* $|B(t)| \leqslant \delta$ *for all* t *in* J *such that*

$$\dot{x} = \left[A(t) + B(t)\right]x \tag{3}$$

has a solution $y_0(t)$ *with*

$$0 < \Delta \leqslant \left|y_0(t)\right| \leqslant L < \infty$$

for all t *in* J *and also*

$$\left|y_0(0) - x_0(0)\right| < K^{-1}$$

when J *is a half-line.*

Let $\varepsilon > 0$ *be given with* $\varepsilon < \alpha/2$. *Then if* δ *is sufficiently small,* (3) *has a trichotomy on* J *with constant depending only on* K, L, Δ (*and* $|y_0(0) - x_0(0)|$ *when* J *is a half-line*) *and exponent* $\alpha - \varepsilon$.

Note first that the shifted equation

$$\dot{x} = \left[A(t) + \alpha/2\right]x$$

has an exponential dichotomy on J with projection P_+ and constants $2K$, $\alpha/2$. It follows from the roughness theorem for dichotomies in [5, Lecture 5] that, if δ is sufficiently small, the perturbed system

$$\dot{x} = \left[A(t) + B(t) + \alpha/2\right]x \tag{4}$$

has an exponential dichotomy on J with both exponents $\alpha/2 - \varepsilon$ and constant K_1 depending on K and projection Q_+ having the same rank as P_+. In particular, if $Y(t)$ is the fundamental matrix of (3) with $Y(0) = I$, then

$$\left|Y(t)Q_+Y^{-1}(s)\right| \leqslant K_1\mathrm{e}^{-(\alpha-\varepsilon)(t-s)} \tag{5}$$

for $t \geqslant s$.

Next the shifted equation

$$\dot{x} = \left[A(t) - \alpha/2\right]x$$

has an exponential dichotomy on J with projection $P_0 + P_+$ and constants $2K$, $\alpha/2$. It follows from the roughness theorem for dichotomies that, if δ is sufficiently small, the perturbed system

$$\dot{x} = \left[A(t) + B(t) - \alpha/2\right]x$$

has an exponential dichotomy on J with projection $I - Q_-$ having the same rank as $P_0 + P_+$ with exponent $\alpha/2 - \varepsilon$ and constant K_1. In particular,

$$\left|Y(t)Q_-Y^{-1}(s)\right| \leqslant K_1\mathrm{e}^{-(\alpha-\varepsilon)(s-t)} \tag{6}$$

for $t \leqslant s$.

Now if $J = \mathbf{R}$ or $\mathbf{R}_+$,

$$\mathcal{N}(Q_-) = \left\{\xi\colon \sup_{t\geqslant 0} \mathrm{e}^{-\alpha t/2}\left|Y(t)\xi\right| < \infty\right\},$$
$$\mathcal{R}(Q_+) = \left\{\xi\colon \sup_{t\geqslant 0} \mathrm{e}^{\alpha t/2}\left|Y(t)\xi\right| < \infty\right\}$$

so that $\mathcal{R}(Q_+) \subset \mathcal{N}(Q_-)$ and $y_0(0) \in \mathcal{N}(Q_-)$. It follows that $Q_-Q_+ = 0$ and $Q_-y_0(0) = 0$. Similarly, if $J = \mathbf{R}$ or $\mathbf{R}_-$, $Q_+Q_- = 0$ and $Q_+y_0(0) = 0$.

Then, when $J = \mathbf{R}$, if we define $Q_0 = I - Q_+ - Q_-$, we see that Q_0, Q_+, Q_- are supplementary projections such that the range of Q_0 is spanned by $y_0(0)$. Now for all t and s

$$\left|y_0(t)\right| \leqslant L\Delta^{-1}\left|y_0(s)\right|$$

and so for all ξ

$$\left|Y(t)Q_0\xi\right| \leqslant L\Delta^{-1}\left|Y(s)Q_0\xi\right|.$$

Hence

$$\left|Y(t)Q_0Y^{-1}(s)\xi\right| \leqslant L\Delta^{-1}\left|Y(s)Q_0Y^{-1}(s)\xi\right|.$$

However,

$$\left|Y(s)Q_0Y^{-1}(s)\right| = \left|Y(s)(I - Q_+ - Q_-)Y^{-1}(s)\right| \leqslant 2K_1 + 1$$

so that

$$\left|Y(t)Q_0Y^{-1}(s)\right| \leqslant L(2K_1+1)\Delta^{-1}$$

for all t and s. This together with (5) and (6) shows that (3) has a trichotomy if δ is sufficiently small with constant $\max\{K_1, L(2K_1+1)\Delta^{-1}\}$ and exponent $\alpha - \varepsilon$.

Now suppose $J = \mathbf{R}_+$. Coppel chooses Q_+ so that

$$\mathcal{N}(Q_+) = \mathcal{N}(P_+) = \operatorname{span}\bigl\{x_0(0)\bigr\} \oplus \mathcal{R}(P_-)$$

and $|Q_+ - P_+| \leqslant N\delta$, where N depends only on K and α. Similarly, he chooses Q_- so that

$$\mathcal{R}(Q_-) = \mathcal{R}(P_-)$$

and $|Q_- - P_-| \leqslant N\delta$. Since $\mathcal{R}(Q_+) \subset \mathcal{N}(Q_-)$, $y_0(0) \in \mathcal{N}(Q_-)$ and clearly $y_0(0) \notin \mathcal{R}(Q_+)$ it follows by consideration of the dimensions that

$$\mathcal{N}(Q_-) = \operatorname{span}\bigl\{y_0(0)\bigr\} \oplus \mathcal{R}(Q_+).$$

Then

$$\mathbf{R}^n = \mathcal{N}(Q_-) \oplus \mathcal{R}(Q_-) = \operatorname{span}\bigl\{y_0(0)\bigr\} \oplus \mathcal{R}(Q_+) \oplus \mathcal{R}(Q_-). \tag{7}$$

Let $\tilde{Q}_+$ be the projection with range $\mathcal{R}(Q_+)$ and nullspace $\operatorname{span}\{y_0(0)\} \oplus \mathcal{R}(Q_-)$ and set $\tilde{Q}_0 = I - \tilde{Q}_+ - Q_-$. We see that $\tilde{Q}_0$, $\tilde{Q}_+$, Q_- are supplementary projections such that the range of $\tilde{Q}_0$ is spanned by $y_0(0)$.

By [5, p. 14], we know we still get a dichotomy for (4) with the altered projection $\tilde{Q}_+$ with exponent $\alpha/2 - \varepsilon$ but different constant depending on K, α and $|\tilde{Q}_+ - Q_+|$. However we need to ensure that the constant can be chosen as a fixed number depending only on the other constants provided δ is sufficiently small. To this end, we need to estimate $|\tilde{Q}_+ - Q_+|$. Using $P_0 + P_+ + P_- = I$, $\tilde{Q}_+Q_+ = Q_+$, $\tilde{Q}_+Q_- = 0$ and $Q_+P_- = 0$, we find that

$$\begin{aligned}
|\tilde{Q}_+ - Q_+| &= \bigl|(\tilde{Q}_+ - Q_+)P_0 + (\tilde{Q}_+ - Q_+)(P_+ + P_-)\bigr| \\
&= \bigl|(\tilde{Q}_+ - Q_+)P_0 + (\tilde{Q}_+ - Q_+)(P_+ + P_- - Q_+ - Q_-)\bigr| \\
&\leqslant \bigl|(\tilde{Q}_+ - Q_+)P_0\bigr| + 2N\delta|\tilde{Q}_+ - Q_+|.
\end{aligned}$$

Now if $P_0x = \lambda x_0(0)$ so that $|\lambda| \leqslant K|x|$,

$$\begin{aligned}
&\bigl|(\tilde{Q}_+ - Q_+)P_0x\bigr| \\
&\quad = |\lambda|\bigl|(\tilde{Q}_+ - Q_+)x_0(0)\bigr| \\
&\quad \leqslant K|x|\bigl|(\tilde{Q}_+ - Q_+)x_0(0)\bigr|
\end{aligned}$$

$$\begin{aligned}&= K|x|\big|\tilde{Q}_+\big(x_0(0)-y_0(0)\big)\big| \quad \text{since } Q_+x_0(0)=\tilde{Q}_+y_0(0)=0\\ &\leqslant K|x||\tilde{Q}_+|\big|x_0(0)-y_0(0)\big|\\ &\leqslant K|x|\big[|Q_+|+|\tilde{Q}_+-Q_+|\big]\big|x_0(0)-y_0(0)\big|.\end{aligned}$$

It follows that

$$\begin{aligned}&|\tilde{Q}_+-Q_+|\\ &\quad\leqslant K\big[|Q_+|+|\tilde{Q}_+-Q_+|\big]\big|x_0(0)-y_0(0)\big|+2N\delta|\tilde{Q}_+-Q_+|\\ &\quad\leqslant KK_1\big|x_0(0)-y_0(0)\big|+\big(K\big|x_0(0)-y_0(0)\big|+2N\delta\big)|\tilde{Q}_+-Q_+|.\end{aligned}$$

So, provided

$$\begin{aligned}&2N\delta<1-K\big|x_0(0)-y_0(0)\big|,\\ &|\tilde{Q}_+-Q_+|\leqslant\big(1-K\big|x_0(0)-y_0(0)\big|-2N\delta\big)^{-1}KK_1\big|x_0(0)-y_0(0)\big|.\end{aligned}$$

Then it follows from [5, p. 14] that (4) has an exponential dichotomy with the altered projection $\tilde{Q}_+$, with the same exponent $\alpha/2-\varepsilon$ and with constant depending only on K, K_1 and $|x_0(0)-y_0(0)|$, provided δ is sufficiently small. Then we finish the proof that (3) has a trichotomy on $\mathbf{R}_+$ as in the case $J=\mathbf{R}$.

The case $J=\mathbf{R}_-$ is similarly handled.

REMARK 2.8. *Smoothness of the projections.* We can show the smoothness of the projections in a trichotomy with respect to a parameter. Suppose (1) has a trichotomy as in the definition. Let $B(t,\mu)$ be a continuous matrix function where the continuity in μ is uniform in t and $B(t,0)=0$. Suppose also that the system

$$\dot{x}=\big[A(t)+B(t,\mu)\big]x \tag{8}$$

has for μ small a solution $y_0(t,\mu)$ with $0<\Delta\leqslant|y_0(t,\mu)|\leqslant L<\infty$ such that $y_0(0,\mu)$ is continuous. Then by Remark 2.7, if μ is sufficiently small, system (8) has a trichotomy on J. Now we suppose in addition that $B_\mu(t,\mu)$ exists and is bounded and continuous where the continuity in μ is uniform with respect to t and also that $y_0(0,\mu)$ is C^1 in μ.

Let the projections be $Q_0(\mu)=I-Q_+(\mu)-Q_-(\mu)$, $Q_+(\mu)$ and $Q_-(\mu)$ as found in Remark 2.7. Now it follows from theorems on exponential dichotomies (see Theorem 4 in [13], Proposition 2.3 in [18]) that $Q_+(\mu)$ and $Q_-(\mu)$ are C^1 in μ. This completes the proof when $J=\mathbf{R}$. Suppose now $J=\mathbf{R}_+$. Then we found in (7) that

$$\mathbf{R}^n=\operatorname{span}\big\{y_0(0,\mu)\big\}\oplus\mathcal{R}\big(Q_+(\mu)\big)\oplus\mathcal{R}\big(Q_-(\mu)\big) \tag{9}$$

and we let $\tilde{Q}_+(\mu)$ be the projection with range $\mathcal{R}(Q_+(\mu))$ and nullspace $\operatorname{span}\{y_0(0,\mu)\}\oplus\mathcal{R}(Q_-(\mu))$ and set $\tilde{Q}_0(\mu)=I-\tilde{Q}_+(\mu)-Q_-(\mu)$. Since the subspaces in the splitting (9) are C^1 in μ, it follows that the associated projections $\tilde{Q}_0(\mu)$, $\tilde{Q}_+(\mu)$ and $Q_-(\mu)$ are C^1 in μ also.

Next we develop a necessary and sufficient condition for a trichotomy in terms of exponential dichotomy of an associated difference equation.

PROPOSITION 2.9. *Suppose $A(t)$ is a continuous matrix function with $|A(t)| \leqslant M$ for all t in $\mathbf{R}$. Let $x_0(t)$ be a nonzero bounded solution of* (1) *with $0 < \Delta \leqslant |x_0(t)| \leqslant L < \infty$ for all t.*

Suppose $\{s_k\}_{k\in Z}$ is a sequence of times such that for all k, $0 < s_{\min} \leqslant s_{k+1} - s_k \leqslant s_{\max} < \infty$ and let $\{Q_k\}_{k\in Z}$ be a sequence of projections of rank $n-1$ *with $|Q_k|, |I - Q_k| \leqslant N$ such that the nullspace of Q_k is spanned by $x_0(s_k)$.*

Then (1) *has a trichotomy on* $\mathbf{R}$ *if and only if the difference equation*

$$u_{k+1} = Q_{k+1}X(s_{k+1})X^{-1}(s_k)u_k, \quad u_k \in \mathcal{R}(Q_k),\ k \in Z, \tag{10}$$

has an exponential dichotomy, where $X(t)$ is the fundamental matrix for (1) *with $X(0) = I$.*

PROOF. We write $A_k = X(s_{k+1})X^{-1}(s_k)$ and note that

$$Q_{k+1}A_kQ_k = Q_{k+1}A_k \tag{11}$$

since $A_kx_0(s_k) = x_0(s_{k+1})$.

Suppose first that (1) has a trichotomy and let $P_0(t)$, $P_+(t)$ and $P_-(t)$ be the associated projections, where $P_\sigma(t) = X(t)P_\sigma X^{-1}(t)$. Then, by Remark 2.2, the range of $P_0(t)$ is spanned by $x_0(t)$. Define the sequence

$$R_k = Q_kP_k^+,$$

where $P_k^+ = P_+(s_k)$. Note that $R_kP_k^+ = R_k$ and since $P_k^+x_0(s_k) = 0$ also $R_kQ_k = R_k$. Then

$$R_k^2 = R_kQ_kP_k^+ = R_kP_k^+ = R_k$$

so that R_k is a projection. Moreover, R_k is invariant with respect to (10) since

$$\begin{aligned} Q_{k+1}A_kR_k &= Q_{k+1}A_kQ_kP_k^+ \\ &= Q_{k+1}A_kP_k^+ \\ &= Q_{k+1}P_{k+1}^+A_k \\ &= R_{k+1}A_k \\ &= R_{k+1}Q_{k+1}A_k. \end{aligned}$$

Now the transition matrix for (10) is given by

$$\Phi(k,m) = \begin{cases} Q_kA_{k-1}\cdots A_m & \text{if } k > m, \\ I & \text{if } k = m, \\ Q_kA_k^{-1}\cdots A_{m-1}^{-1} & \text{if } k < m \end{cases}$$

since, for example, $\Phi(k,k-1)=Q_kA_{k-1}$ and if $k>m+1$, then

$$\Phi(k,m)=\Phi(k,k-1)\Phi(k-1,m)$$

so that if we assume $\Phi(k-1,m)=Q_{k-1}A_{k-2}\cdots A_m$ then, using (11),

$$\Phi(k,m)=Q_kA_{k-1}Q_{k-1}A_{k-2}\cdots A_m=Q_kA_{k-1}A_{k-2}\cdots A_m$$

so that the formula for $k>m$ follows by induction on k. Then if $k>m$

$$\begin{aligned}\left|\Phi(k,m)R_m\right|&=|Q_kA_{k-1}\cdots A_mQ_mP_m^+|\\&=\left|Q_kX(s_k)X^{-1}(s_m)P_+(s_m)\right|\\&\leqslant NK\mathrm{e}^{-\alpha(s_k-s_m)}\\&\leqslant NK\mathrm{e}^{-\alpha s_{\min}(k-m)}.\end{aligned}$$

Similarly, if $k<m$,

$$\left|\Phi(k,m)(I-R_m)\right|=\left|Q_kX(s_k)X^{-1}(s_m)P_-(s_m)\right|\leqslant NK\mathrm{e}^{-\alpha s_{\min}(m-k)}.$$

Finally, if $k=m$,

$$\left|\Phi(k,m)R_m\right|=|R_m|\leqslant NK.$$

Hence (10) has an exponential dichotomy with projections R_k and constants NK and $\mathrm{e}^{-\alpha s_{\min}}$.

Now, conversely, suppose (10) has an exponential dichotomy with projections $R_k:\mathcal{R}(Q_k)\mapsto\mathcal{R}(Q_k)$ and constants K, λ. Then a solution u_k of Eq. (10) with $u_0\in\mathcal{R}(R_0)$ satisfies

$$|u_k|\leqslant K\lambda^{k-m}|u_m|$$

for $m\leqslant k$. Define

$$\eta_k=-\sum_{\ell=k}^{\infty}\alpha_{\ell+1}(A_\ell u_\ell),$$

where the linear functional $\alpha_k:\mathbf{R}^n\mapsto\mathbf{R}$ is defined by

$$(I-Q_k)v=\alpha_k(v)x_0(s_k).$$

Note that

$$|\alpha_k|\leqslant N\Delta^{-1}$$

so that if $k \geqslant m$

$$|\eta_k| \leqslant \sum_{\ell=k}^{\infty} N\Delta^{-1}\mathrm{e}^{Ms_{\max}}|u_\ell| \leqslant \sum_{\ell=k}^{\infty} N\Delta^{-1}\mathrm{e}^{Ms_{\max}}K\lambda^{\ell-m}|u_m| \leqslant K_1\lambda^{k-m}|u_m|,$$

where

$$K_1 = NK\mathrm{e}^{Ms_{\max}}\Delta^{-1}(1-\lambda)^{-1}.$$

Then we define

$$v_k = \eta_k x_0(s_k) + u_k.$$

Note that for all k

$$\begin{aligned} v_{k+1} &= \eta_{k+1}x_0(s_{k+1}) + u_{k+1} \\ &= \big[\eta_k + \alpha_{k+1}(A_k u_k)\big]x_0(s_{k+1}) + Q_{k+1}A_k u_k \\ &= \eta_k x_0(s_{k+1}) + (I - Q_{k+1})A_k u_k + Q_{k+1}A_k u_k \\ &= \eta_k A_k x_0(s_k) + A_k u_k \\ &= X(s_{k+1})X^{-1}(s_k)v_k \end{aligned}$$

and that for $k \geqslant m$

$$|v_k| \leqslant K_1 L\lambda^{k-m}|u_m| + K\lambda^{k-m}|u_m| = (K_1 L + K)|u_m|\lambda^{k-m},$$

where we see that

$$|u_m| = |Q_m v_m| \leqslant N|v_m|$$

so that for $k \geqslant m$

$$|v_k| \leqslant K_2|v_m|\lambda^{k-m},$$

where

$$K_2 = (K_1 L + K)N.$$

Next note that

$$\eta_0 = -\sum_{k=0}^{\infty}\alpha_{k+1}(A_k u_k) = -\sum_{k=0}^{\infty}\alpha_{k+1}(A_k Q_k A_{k-1}\cdots A_0 u_0).$$

So what we have shown is that if we define the subspace

$$E^s = \{v_0 = \beta(u_0)x_0(s_0) + u_0\colon\ u_0 \in \mathcal{R}(R_0)\}$$

of $\mathbf{R}^n$, where

$$\beta(u_0) = -\sum_{k=0}^{\infty} \alpha_{k+1}(A_k Q_k A_{k-1} \cdots A_0 u_0),$$

then for $v_0 \in E^s$,

$$|X(s_k)X^{-1}(s_0)v_0| \leqslant K_2 \lambda^{k-m} |X(s_m)X^{-1}(s_0)v_0|$$

for $m \leqslant k$. Now if $s \leqslant t$, we can find $m \leqslant k$ such that

$$s_m \leqslant s < s_{m+1}, \qquad s_k \leqslant t < s_{k+1}.$$

Then

$$\begin{aligned}
|X(t)X^{-1}(s_0)v_0| &\leqslant \mathrm{e}^{Ms_{\max}} |X(s_k)X^{-1}(s_0)v_0| \\
&\leqslant \mathrm{e}^{Ms_{\max}} K_2 \lambda^{k-m} |X(s_m)X^{-1}(s_0)v_0| \\
&\leqslant \mathrm{e}^{2Ms_{\max}} K_2 \lambda^{k-m} |X(s)X^{-1}(s_0)v_0| \\
&\leqslant K_2 \mathrm{e}^{2Ms_{\max}} \lambda^{\frac{t-s}{s_{\max}}-1} |X(s)X^{-1}(s_0)v_0| \\
&= K_2 \mathrm{e}^{2Ms_{\max}} \lambda^{-1} \mathrm{e}^{\frac{\ln\lambda}{s_{\max}}(t-s)} |X(s)X^{-1}(s_0)v_0|.
\end{aligned}$$

So if $v_0 \in E^s$, then for $s \leqslant t$

$$|X(t)X^{-1}(s_0)v_0| \leqslant K_3 \mathrm{e}^{-\alpha(t-s)} |X(s)X^{-1}(s_0)v_0|, \tag{12}$$

where

$$K_3 = K_2 \mathrm{e}^{2Ms_{\max}}/\lambda, \qquad \alpha = -\ln\lambda/s_{\max}.$$

Similarly, there is a subspace

$$E^u = \{v_0 = \gamma(v_0)x_0(s_0) + u_0\colon\ u_0 \in \mathcal{N}(R_0)\}$$

of $\mathbf{R}^n$ such that if $v_0 \in E^u$,

$$|X(t)X^{-1}(s_0)v_0| \leqslant K_3 \mathrm{e}^{-\alpha(s-t)} |X(s)X^{-1}(s_0)v_0| \tag{13}$$

for $s \geqslant t$.

Next we show that $E^s \cap E^u = \{0\}$. Let v_0 be in this intersection. Then there exist $u_0 \in \mathcal{R}(R_0)$ and $\tilde{u}_0 \in \mathcal{N}(R_0)$ such that

$$v_0 = \beta(u_0)x_0(s_0) + u_0 = \gamma(\tilde{u}_0)x_0(s_0) + \tilde{u}_0.$$

Multiplying through by $I - Q_0$, we see that $\beta(u_0) = \gamma(\tilde{u}_0)$ which implies $u_0 = \tilde{u}_0$ and so both are zero. Thus $v_0 = 0$ and our assertion is proved.

Next note that $x_0(s_0)$ is not in $E^s \oplus E^u$, since if there exist $u_0 \in \mathcal{R}(R_0)$ and $\tilde{u}_0 \in \mathcal{N}(R_0)$ such that

$$x_0(s_0) = \beta(u_0)x_0(s_0) + u_0 + \gamma(\tilde{u}_0)x_0(s_0) + \tilde{u}_0,$$

then

$$x_0(s_0) = \bigl(\beta(u_0) + \gamma(\tilde{u}_0)\bigr)x_0(s_0) + u_0 + \tilde{u}_0.$$

Since $x_0(s_0)$ and $u_0 + \tilde{u}_0$ are linearly independent, it follows that $u_0 + \tilde{u}_0 = 0$ and hence $u_0 = \tilde{u}_0 = 0$ and so $x_0(s_0) = 0$, which is not true. So $x_0(s_0)$ is not in $E^s \oplus E^u$. Then since

$$\dim E^s + \dim E^u = \operatorname{rank} R_0 + (n - 1 - \operatorname{rank} R_0) = n - 1,$$

it follows that

$$\mathbf{R}^n = \operatorname{span}\bigl\{x_0(s_0)\bigr\} \oplus E^s \oplus E^u.$$

Let P_0, P_+, P_- be the projections associated with this splitting. Then it follows from (12) and (13) that for all ξ

$$\bigl|X(t)X^{-1}(s_0)P_+\xi\bigr| \leqslant K_3 e^{-\alpha(t-s)}\bigl|X(t)X^{-1}(s_0)P_+\xi\bigr| \quad (s \leqslant t)$$

and

$$\bigl|X(t)X^{-1}(t_0)P_-\xi\bigr| \leqslant K_3 e^{-\alpha(s-t)}\bigl|X(s)X^{-1}(s_0)P_+\xi\bigr| \quad (s \geqslant t).$$

Also since $|x_0(t)| \leqslant L\Delta^{-1}|x_0(s)|$ for all s, t, it follows for all t, s, ξ that

$$\bigl|X(t)X^{-1}(s_0)P_0\xi\bigr| \leqslant L\Delta^{-1}\bigl|X(s)X^{-1}(s_0)P_0\xi\bigr|.$$

Then, in view of Remark 2.5, it follows that (1) has a trichotomy on $\mathbf{R}$. This completes the proof of the proposition. □

3. Hyperbolic periodic orbits and their stable and unstable manifolds

In this section we study an autonomous system in $\mathbf{R}^n$

$$\dot{x} = f(x), \tag{14}$$

where f is C^1 and for all x

$$\left|f(x)\right| \leqslant M_0, \qquad \left|f'(x)\right| \leqslant M_1.$$

We denote by $\phi^t(x)$ the corresponding flow which, under these conditions, is defined for all t and x. Frequently we shall use the fact that

$$\left|D\phi^t(x)\right| \leqslant \mathrm{e}^{M_1|t|},$$

which follows from Gronwall's inequality, and also the fact that

$$D\phi^t(x)f(x) = f\bigl(\phi^t(x)\bigr).$$

We first define the Poincaré map associated with a periodic orbit of this system. Then we construct the local and global stable and unstable manifolds of a hyperbolic periodic orbit, thereby introducing the concept of asymptotic phase.

3.1. *Poincaré map*

First we define a more general Poincaré map. For this, we need the following lemma.

LEMMA 3.1. *Let $f(x)$ be a C^1 vectorfield in $\mathbf{R}^n$ with $|f(x)| \leqslant M_0$ and $|f'(x)| \leqslant M_1$. Let x be a point in $\mathbf{R}^n$, v a unit vector and T a real number such that $\langle f(y), v\rangle > 0$, where $y = \phi^T(x)$. Set*

$$\alpha = \frac{\langle f(y), v\rangle}{4M_0M_1}, \qquad \delta = \frac{\mathrm{e}^{-M_1T}\langle f(y), v\rangle}{4M_1}\min\left\{1, \frac{\langle f(y), v\rangle}{2M_0}\right\}.$$

Then if $|z - x| < \delta$, there exists a unique $\tau = \tau(z)$ such that

$$\bigl\langle \phi^\tau(z) - y, v\bigr\rangle = 0$$

and $|\tau - T| \leqslant \alpha$. Moreover,

$$\left|\tau(z) - T\right| \leqslant 2\bigl\langle f(y), v\bigr\rangle^{-1}\mathrm{e}^{M_1T}|z - x|, \tag{15}$$

$\tau(z)$ is a C^1 function with

$$\left|\tau'(z)\right| \leqslant 2\bigl\langle f(y), v\bigr\rangle^{-1}\mathrm{e}^{M_1(T+\alpha)}$$

and

$$\bigl\langle f\bigl(\phi^{\tau(z)}(z)\bigr), v\bigr\rangle \geqslant \frac{1}{2}\bigl\langle f(y), v\bigr\rangle.$$

PROOF. We need to solve the equation

$$g(\tau, z) = \langle \phi^\tau(z) - y, v \rangle = 0$$

for τ when $|z - x| < \delta$. Note that

$$g(T, x) = 0, \qquad g_\tau(T, x) = \langle f(y), v \rangle.$$

Then the equation holds if and only if

$$S\tau = \tau,$$

where

$$S\tau = T - g_\tau(T, x)^{-1}\eta(\tau, z),$$

with

$$\eta(\tau, z) = g(\tau, z) - g(T, x) - g_\tau(T, x)(\tau - T).$$

Note that if $|\tau_i - T| \leqslant \alpha$ and $|z - x| < \delta$, then

$$\begin{aligned} \bigl|\eta(\tau_1, z) - \eta(\tau_2, z)\bigr| &= \bigl|g(\tau_1, z) - g(\tau_2, z) - g_\tau(T, x)(\tau_1 - \tau_2)\bigr| \\ &= \left| \int_0^1 g_\tau\bigl(\theta\tau_1 + (1-\theta)\tau_2, z\bigr) - g_\tau(T, x)\, \mathrm{d}\theta (\tau_1 - \tau_2) \right|. \end{aligned}$$

Now if $|\tau - T| \leqslant \alpha$ and $|z - x| < \delta$,

$$\begin{aligned} \bigl|g_\tau(\tau, z) - g_\tau(T, x)\bigr| &\leqslant \bigl|f\bigl(\phi^\tau(z)\bigr) - f\bigl(\phi^T(x)\bigr)\bigr| \\ &\leqslant M_1\bigl|\phi^\tau(z) - \phi^T(x)\bigr| \\ &\leqslant M_1\bigl[\bigl|\phi^\tau(z) - \phi^T(z)\bigr| + \bigl|\phi^T(z) - \phi^T(x)\bigr|\bigr] \\ &\leqslant M_1\bigl[M_0|\tau - T| + \mathrm{e}^{M_1 T}|z - x|\bigr] \\ &\leqslant M_1\bigl[M_0\alpha + \mathrm{e}^{M_1 T}\delta\bigr]. \end{aligned} \tag{16}$$

It follows that if $|\tau_i - T| \leqslant \alpha$ and $|z - x| < \delta$, then

$$\bigl|\eta(\tau_1, z) - \eta(\tau_2, z)\bigr| \leqslant M_1[M_0\alpha + \mathrm{e}^{M_1 T}\delta]|\tau_1 - \tau_2|.$$

Next note that

$$\bigl|\eta(T, z)\bigr| = \bigl|g(T, z) - g(T, x)\bigr| \leqslant \bigl|\phi^T(z) - \phi^T(x)\bigr| \leqslant \mathrm{e}^{M_1 T}|z - x|.$$

Using these we see that if $|\tau - T| \leqslant \alpha$ and $|z - x| < \delta$, then

$$\begin{aligned}|S\tau - T| &\leqslant \langle f(y), v\rangle^{-1}\big[\big|\eta(\tau, z) - \eta(T, z)\big| + \big|\eta(T, z)\big|\big]\\ &\leqslant \langle f(y), v\rangle^{-1}\big[M_1[M_0\alpha + \mathrm{e}^{M_1 T}\delta]|\tau - T| + \mathrm{e}^{M_1 T}|z - x|\big]\end{aligned}$$

so that

$$|S\tau - T| \leqslant \frac{1}{2}|\tau - T| + \langle f(y), v\rangle^{-1}\mathrm{e}^{M_1 T}|z - x|. \tag{17}$$

In particular, this means that

$$|S\tau - T| \leqslant \frac{1}{2}\alpha + \langle f(y), v\rangle^{-1}\mathrm{e}^{M_1 T}\delta \leqslant \alpha.$$

Next, by similar reasoning, if $|\tau_i - T| \leqslant \alpha$ and $|z - x| < \delta$, then

$$|S\tau_1 - S\tau_2| \leqslant \langle f(y), v\rangle^{-1}M_1[M_0\alpha + \mathrm{e}^{M_1 T}\delta]|\tau_1 - \tau_2| \leqslant \frac{1}{2}|\tau_1 - \tau_2|.$$

It follows by the contraction mapping principle that if $|z - x| < \delta$, S has a unique fixed point τ in $|\tau - T| \leqslant \alpha$. The inequality (15) follows from (17) by putting $S\tau = \tau$. This completes the proof of the first part of the lemma.

That $\tau(x)$ is C^1 follows from standard results concerning smoothness of fixed point of a uniform contraction (see, for example, Lemma 3.8 below). Now

$$\tau'(z)h = -\frac{g_z(\tau(z), z)h}{g_\tau(\tau(z), z)} = -\frac{\langle D\phi^{\tau(z)}(z)h, v\rangle}{\langle f(\phi^{\tau(z)}(z)), v\rangle}. \tag{18}$$

To estimate this, we use (16) which implies that

$$\big|g_\tau\big(\tau(z), z\big) - g_\tau(T, x)\big| \leqslant M_1[M_0\alpha + \mathrm{e}^{M_1 T}\delta] \leqslant \frac{1}{2}\langle f(y), v\rangle.$$

Hence, since $g_\tau(T, x) = \langle f(y), v\rangle$,

$$g_\tau\big(\tau(z), z\big) \geqslant \frac{1}{2}\langle f(y), v\rangle.$$

Next

$$\big|\langle D\phi^{\tau(z)}(z)h, v\rangle\big| \leqslant \big|D\phi^{\tau(z)}(z)\big||h| \leqslant \mathrm{e}^{M_1\tau(z)}|h| \leqslant \mathrm{e}^{M_1(T+\alpha)}|h|.$$

Thus we obtain the inequality for $|\tau'(z)|$ and we have also shown in passing the last inequality in the statement of the lemma. Thus we complete the proof of the lemma. □

REMARK 3.2. We can write the τ found in the lemma as $\tau(z, x, v, T)$. We observe here that τ is a C^1 function of (z, x, v, T) on the open set of (z, x, v, T) for which $|z-x| < \delta = \delta(x, v, T)$. This follows from the smoothness of the fixed point of a uniform contraction (see, for example, Lemma 3.8 below).

We use this lemma to define a general Poincaré map. Consider a system (14) with a nonconstant solution $u(t)$. Let $t_1 < t_2$ be two times and let v_i $(i = 1, 2)$ be a unit vector such that $\langle f(u(t_i)), v_i\rangle > 0$. Let $W_i = \{v\colon \langle v, v_i\rangle = 0\}$ and set $C_i = u(t_i) + W_i$. Also set

$$\alpha = \bigl\langle f\bigl(u(t_2)\bigr), v_2\bigr\rangle / 4M_0M_1$$

and

$$\delta = \min\left\{\frac{\mathrm{e}^{-M_2(t_2-t_1)}\langle f(u(t_2)), v_2\rangle}{4M_1}\min\left\{1, \frac{\langle f(u(t_2)), v_2\rangle}{2M_0}\right\}, \frac{\langle f(u(t_1)), v_1\rangle}{M_1}\right\}.$$

Then, by Lemma 3.1, if $x \in C_1$ with $|x - u(t_1)| < \delta$, there exists a unique $\tau = \tau(x)$ in $|\tau - (t_2 - t_1)| < \alpha$ such that $\phi^\tau(x) \in C_2$. Moreover, $\tau(x)$ is a C^1 function, $\tau(u(t_1)) = t_2 - t_1$ and

$$\bigl|\tau(x) - (t_2 - t_1)\bigr| \leqslant 2\bigl\langle f\bigl(u(t_2)\bigr), v_2\bigr\rangle^{-1}\mathrm{e}^{M_1(t_2-t_1)}\bigl|x - u(t_1)\bigr|.$$

Then for $x \in C_1$ with $|x - u(t_1)| < \delta$ we define the Poincaré map

$$P(x) = \phi^{\tau(x)}(x).$$

Note that

$$P\bigl(u(t_1)\bigr) = u(t_2).$$

Also, as in (18), for $x \in C_1$ and $\xi \in W_1$,

$$\tau'(x)\xi = -\frac{\langle D\phi^{\tau(x)}(x)\xi, v_2\rangle}{\langle f(\phi^{\tau(x)}(x)), v_2\rangle}$$

so that

$$DP(x)\xi = f\bigl(P(x)\bigr)\tau'(x)\xi + D\phi^{\tau(x)}(x)\xi = Q_x D\phi^{\tau(x)}(x)\xi, \tag{19}$$

where Q_x is the projection on to W_2 along $f(P(x))$. Note that if $DP(x)\xi = 0$, then $D\phi^{\tau(x)}(x)\xi = \lambda f(P(x))$, where $\lambda = -\tau'(x)\xi$, and so

$$D\phi^{\tau(x)}(x)\bigl(-\lambda f(x) + \xi\bigr) = 0$$

from which it follows that $-\lambda f(x) + \xi = 0$. Now since $|x - u(t_1)| < \delta$,

$$\bigl\langle f(x), v_1\bigr\rangle > \bigl\langle f\bigl(u(t_1)\bigr), v_1\bigr\rangle - M_1\delta \geqslant 0$$

and so we must have $\lambda = 0$ and $\xi = 0$. So $DP(x)$ is injective and hence invertible. It follows that P is a diffeomorphism on $x \in C_1$, $|x - u(t_1)| < \delta$.

We use the notation $P(u(t_1), t_1, t_2, v_1, v_2)$ for the Poincaré map just defined.

DEFINITION 3.3. We say a T-periodic orbit $u_0(t)$ of (14) is *hyperbolic* if all but one of its Floquet multipliers lie off the unit circle.

PROPOSITION 3.4. *A T-periodic orbit $u_0(t)$ of* (14) *is hyperbolic if and only if $u_0(0)$ is hyperbolic as a fixed point of the Poincaré map*

$$P\big(u_0(0), 0, T, v, v\big), \quad v = \frac{u_0'(0)}{|u_0'(0)|}.$$

PROOF. Write $P = P(u_0(0), 0, T, v, v)$. First we note that

$$P\big(u_0(0)\big) = u_0(T) = u_0(0).$$

Next we know from (19) that

$$DP\big(u_0(0)\big) = QD\phi^T\big(u_0(0)\big),$$

where Q is the orthogonal projection onto the orthogonal complement W (the domain of $DP(u_0(0))$) of $u_0'(0) = f(u_0(0))$. Also we know that

$$D\phi^T\big(u_0(0)\big) f\big(u_0(0)\big) = f\big(u_0(0)\big).$$

We choose a basis of $\mathbf{R}^n$ with $f(u_0(0))$ as the first basis vector and with the other basis vectors in W. Then the matrix of $D\phi^T(u_0(0))$ with respect to this basis has the partitioned form

$$\begin{bmatrix} 1 & b \\ 0 & B \end{bmatrix},$$

where B is the matrix of $DP(u_0(0))$. Then the proposition follows immediately since the characteristic polynomial is $(1 - \lambda)\det(B - \lambda I)$. □

3.2. *Local stable and unstable manifolds*

In this subsection we study the local stable and unstable manifolds of a hyperbolic periodic orbit. For later use, we consider a system

$$\dot{x} = f(x, \mu) \tag{20}$$

depending on a parameter μ. We assume that when $\mu = 0$ the system has a hyperbolic T-periodic orbit $u_0(t)$. By standard theorems (see [10]) the perturbed system (20) has a nearby hyperbolic periodic orbit $u(t,\mu)$ such that $u(t,0) = u_0(t)$. This orbit will have period $T(\mu)$ with $T(0) = T$. Note that if $f(x,\mu)$ is C^r, then $u(t,\mu)$ and $T(\mu)$ are C^r also.

In the following proposition, we find the local stable manifold near $u(0,\mu)$ with asymptotic phase 0, that is, we find the solutions $x(t)$ with $x(0)$ near $u(0,\mu)$ such that $|x(t) - u(t,\mu)| \to 0$ as $t \to \infty$.

PROPOSITION 3.5. *Let the function $f(x,\mu)$ be C^{r+2} $(r \geqslant 0)$ and suppose*

$$\dot{x} = f(x,0)$$

has a hyperbolic T-periodic solution $u_0(t)$. Then

(i) *the system*

$$\dot{x} = f_x\bigl(u_0(t),0\bigr)x$$

has a trichotomy with projections P_0, P_+ and P_- and constants K, α;

(ii) *the perturbed system* (20) *has a hyperbolic $T(\mu)$-periodic solution $u(t,\mu)$ where $u(t,\mu)$ and $T(\mu)$ are C^{r+2} functions with $u(t,0) = u_0(t)$ and $T(0) = T$;*

(iii) *suppose $0 < \gamma < \alpha$. For $\Delta > 0$ sufficiently small, there are positive numbers μ_0, ξ_0 depending on Δ such that if $|\mu| < \mu_0$ and $\xi \in \mathcal{R}(P_+)$ satisfies $|\xi| < \xi_0$, there exists a unique solution $x(t) = x^+(t,\xi,\mu)$ of* (20) *such that*

$$\bigl|x(t) - u(t,\mu)\bigr|\mathrm{e}^{\gamma t} \leqslant \Delta \quad (t \geqslant 0), \qquad P_+\bigl[x(0) - u(0,\mu)\bigr] = \xi.$$

Moreover,

$$x^+(t,0,\mu) = u(t,\mu),$$

$x^+(t,\xi,\mu)$ is C^r in its arguments and $x^+_\xi(t,\xi,\mu)$ is the unique solution restricted to $\mathcal{R}(P_+)$ of

$$\dot{Z} = f_x\bigl(x^+(t,\xi,\mu),\mu\bigr)Z$$

such that $\sup_{t\geqslant 0} \mathrm{e}^{\gamma t}|Z(t)| < \infty$ and $P_+Z(0) = P_+$ with, in particular,

$$x^+_\xi(t,0,0) = X(t)P_+,$$

and there is a constant N such that when $r \geqslant 1$,

$$\bigl|x^+_\xi(t,\xi,\mu)\bigr| \leqslant N\mathrm{e}^{-\gamma t}, \quad \bigl|x^+_\mu(t,\xi,\mu) - u_\mu(t,\mu)\bigr| \leqslant N\mathrm{e}^{-\gamma t} \quad (t \geqslant 0)$$

and when $r \geqslant 2$,

$$\bigl|x^+_{\xi\xi}(t,\xi,\mu)\bigr| \leqslant N\mathrm{e}^{-\gamma t} \quad (t \geqslant 0).$$

PROOF. For the linear system

$$\dot{x} = f_x\bigl(u_0(t), 0\bigr)x, \tag{21}$$

1 is a Floquet multiplier of algebraic multiplicity one and the others lie off the unit circle. Now by Floquet theory there is a linear invertible periodic transformation $x = S(t)y$ taking (21) into an autonomous system $\dot{y} = Ay$ with A having zero as an eigenvalue of multiplicity one and the other eigenvalues having nonzero real parts. We define P_0, P_+, P_- to be the supplementary projections corresponding to the splitting of $\mathbf{R}^n$ into the generalized eigenspaces corresponding respectively to the zero eigenvalue, the eigenvalues with negative real parts and the eigenvalues with positive real parts. Note that the projections P_σ commute with A and there exist positive constants L, α (note that α can be taken as any positive number such that $|\mathrm{Re}(\lambda)| > \alpha$ for all eigenvalues λ of A with nonzero real part) such that

$$\begin{aligned}
&|\mathrm{e}^{tA}P_0| \leqslant L \quad \text{for all } t,\\
&|\mathrm{e}^{tA}P_+| \leqslant L\mathrm{e}^{-\alpha t} \quad \text{for } t \geqslant 0,\\
&|\mathrm{e}^{tA}P_-| \leqslant L\mathrm{e}^{\alpha t} \quad \text{for } t \leqslant 0.
\end{aligned}$$

Then $X(t) = S(t)\mathrm{e}^{tA}$ is a fundamental matrix for (21) and, since $X(t)P_\sigma X^{-1}(s) = S(t)\mathrm{e}^{(t-s)A}P_\sigma S^{-1}(s)$, we obtain the inequalities

$$\begin{aligned}
&\bigl|X(t)P_0X^{-1}(s)\bigr| \leqslant K \quad \text{for all } t,\\
&\bigl|X(t)P_+X^{-1}(s)\bigr| \leqslant K\mathrm{e}^{-\alpha(t-s)} \quad \text{for } t \geqslant s,\\
&\bigl|X(t)P_-X^{-1}(s)\bigr| \leqslant K\mathrm{e}^{-\alpha(s-t)} \quad \text{for } t \leqslant s,
\end{aligned}$$

where $K = LM^2$ with M an upper bound for $|S(t)|$ and $|S^{-1}(t)|$. Now if we replace P_σ by $X(0)P_\sigma X^{-1}(0)$, it follows that (21) has a trichotomy on $\mathbf{R}$ with these projections, which we rename as P_σ, and constants K and α. So (i) is proved.

As noted before the proposition, (ii) follows from standard theorems. Now if we change the time scale $\tau = \omega(\mu)t$, where $\omega(\mu) = T/T(\mu)$, then the new system

$$\frac{\mathrm{d}x}{\mathrm{d}\tau} = \omega(\mu)^{-1}f(x,\mu)$$

has the periodic orbit $u(\omega(\mu)^{-1}\tau, \mu)$ which has period T for all μ. So we can assume without loss of generality that in the original system the period of $u(t,\mu)$ is T, independent of μ. The advantage of this is that now $\sup_{t\in\mathbf{R}}|u(t,\mu) - u_0(t)| \to 0$ as $\mu \to 0$.

To prove (iii), we look for solutions $x(t)$ of (20) such that $|x(t) - u(t,\mu)| \to 0$ at an exponential rate as $t \to \infty$. We write

$$x = u(t,\mu) + z.$$

Then

$$\dot{z} = f_x\bigl(u_0(t), 0\bigr)z + h(t, z, \mu), \tag{22}$$

where

$$\begin{aligned} h(t, z, \mu) = {} & \bigl[f_x\bigl(u(t, \mu), \mu\bigr) - f_x\bigl(u_0(t), 0\bigr)\bigr]z \\ & + f\bigl(u(t, \mu) + z, \mu\bigr) - f\bigl(u(t, \mu), \mu\bigr) - f_x\bigl(u(t, \mu), \mu\bigr)z. \end{aligned}$$

Note that $h(t, 0, \mu) = 0$ and

$$\bigl|h_z(t, z, \mu)\bigr| = \bigl|f_x\bigl(u(t, \mu) + z, \mu\bigr) - f_x\bigl(u_0(t), 0\bigr)\bigr| \leqslant \delta\bigl(|z|, |\mu|\bigr),$$

where $\delta(|z|, |\mu|)$ is a continuous function nondecreasing in both arguments which $\to 0$ as $(|z|, |\mu|) \to (0, 0)$.

Given small $\xi \in \mathcal{R}(P_+)$, we look for solutions $z(t)$ of (22) such that

$$P_+z(0) = \xi, \qquad \bigl|z(t)\bigr| \leqslant \Delta e^{-\gamma t} \quad (t \geqslant 0),$$

where Δ is chosen suitably small. First we prove the following lemma.

LEMMA 3.6. *Suppose the linear system*

$$\dot{x} = A(t)x \tag{23}$$

has a trichotomy on $[0, \infty)$ *with projections* P_0, P_+, P_- *and constants* K, α *and let* $0 < \gamma < \alpha$. *Suppose* $\xi \in \mathcal{R}(P_+)$ *and* $h(t)$ *is a continuous function with* $\|h\|_\gamma = \sup_{t \geqslant 0} |h(t)|e^{\gamma t} < \infty$. *Then*

$$x(t) = X(t)\xi + \int_0^t X(t)P_+X^{-1}(s)h(s)\,ds - \int_t^\infty X(t)(I - P_+)X^{-1}(s)h(s)\,ds$$

is the unique solution of

$$\dot{x} = A(t)x + h(t) \tag{24}$$

such that $\|x\|_\gamma < \infty$ *and* $P_+x(0) = \xi$. *Moreover*

$$\|x\|_\gamma \leqslant K|\xi| + K\bigl[(\alpha - \gamma)^{-1} + 2\gamma^{-1}\bigr]\|h\|_\gamma.$$

PROOF. To prove the uniqueness first, note that the difference $x(t)$ between any two such solutions would be a solution of (23) such that $x(t) \to 0$ as $t \to \infty$ and $P_+x(0) = 0$. Now from Remark 2.2 it follows that $x(0) \in \mathcal{R}(P_+)$. So $x(0) = P_+x(0) = 0$. This gives the uniqueness.

To prove the existence, note that

$$\begin{aligned}
&\int_0^t \bigl|X(t)P_+X^{-1}(s)h(s)\bigr|\,\mathrm{d}s + \int_t^\infty \bigl|X(t)(I-P_+)X^{-1}(s)h(s)\bigr|\,\mathrm{d}s\\
&\quad\leqslant \int_0^t K\mathrm{e}^{-\alpha(t-s)}\|h\|_\gamma \mathrm{e}^{-\gamma s}\,\mathrm{d}s + \int_t^\infty 2K\|h\|_\gamma \mathrm{e}^{-\gamma s}\,\mathrm{d}s\\
&\quad= K\bigl[(\alpha-\gamma)^{-1} + 2\gamma^{-1}\bigr]\|h\|_\gamma \mathrm{e}^{-\gamma t}.
\end{aligned}$$

Hence the integrals defining $x(t)$ converge and we find by differentiation that $x(t)$ is a solution of (24). Moreover, using the fact that $|X(t)P_+| \leqslant K\mathrm{e}^{-\gamma t}$ and the previous estimate, we find that $\|x\|_\gamma < \infty$ and that the inequality given in the statement of the lemma holds. □

From this lemma, we deduce another.

LEMMA 3.7. *Suppose the linear system* (23) *satisfies the conditions of Lemma* 3.6 *and let* $0 < \gamma < \alpha$. *Let* $h(t, x, \mu)$ *be a continuous function,* T*-periodic in* t*, satisfying*

$$h(t,0,\mu) = 0, \qquad \bigl|h(t,x_1,\mu) - h(t,x_2,\mu)\bigr| \leqslant L|x_1 - x_2|$$

for all $t \geqslant 0$, $|x_1| \leqslant \Delta$, $|x_2| \leqslant \Delta$, $|\mu| < \mu_0$. *Suppose that*

$$K(\gamma)L = K\bigl[(\alpha-\gamma)^{-1} + 2\gamma^{-1}\bigr]L < 1.$$

Then if $|\mu| < \mu_0$ *and* $\xi \in \mathcal{R}(P_+)$ *with*

$$K|\xi| < \bigl(1 - K(\gamma)L\bigr)\Delta, \tag{25}$$

the equation

$$\dot{x} = A(t)x + h(t,x,\mu)$$

has a unique solution $x(t) = x(t,\xi,\mu)$ *such that* $\|x\|_\gamma \leqslant \Delta$ *and* $P_+x(0) = \xi$. *Moreover*

$$x(t,0,\mu) = 0$$

and

$$\|x\|_\gamma \leqslant K\bigl(1 - K(\gamma)L\bigr)^{-1}|\xi|. \tag{26}$$

Also, if $h(t,x,\mu)$ *is* C^{r+2} $(r \geqslant 0)$ *in* (x,μ) *with all derivatives continuous in* (t,x,μ), *then* $x(t,\xi,\mu)$ *is* C^r *in* (x,μ) *and is continuous in* (t,x,μ) *together with all its derivatives. Moreover,* $x_\xi(t,\xi,\mu)$ *is the unique solution restricted to* $\mathcal{R}(P_+)$ *of*

$$\dot{Z} = \bigl[A(t) + h_x\bigl(t, x(t,\xi,\mu),\mu\bigr)\bigr]Z$$

such that $\|Z\|_\gamma < \infty$ *and* $P_+Z(0) = P_+$,

$$x_\xi(t, 0, 0) = X(t)P_+$$

and there exists a constant N *such that for* $t \geqslant 0$

$$\left|x_\xi(t, \xi, \mu)\right| \leqslant N\mathrm{e}^{-\gamma t}, \quad \left|x_\mu(t, \xi, \mu)\right| \leqslant N\mathrm{e}^{-\gamma t}, \quad \left|x_{\xi\xi}(t, \xi, \mu)\right| \leqslant N\mathrm{e}^{-\gamma t}$$

when these derivatives exist.

PROOF. Consider the Banach space E of continuous functions $x(t)$ on $[0, \infty)$ with $\|x\|_\gamma < \infty$, with $\|x\|_\gamma$ as norm. Let B be the ball of radius Δ and centre 0. Then B is a complete metric space. Next suppose $|\mu| < \mu_0$ and $\xi \in \mathcal{R}(P_+)$ satisfies (25). Then we define a mapping $T : B \mapsto B$ as follows: if $x \in B$, we let $T(x)(t)$ be the unique solution of

$$\dot{x} = A(t)x + h\bigl(t, x(t), \mu\bigr)$$

such that $P_+T(x)(0) = \xi$ and $\|T(x)\|_\gamma < \infty$. This exists by Lemma 3.6 and it also follows from that lemma that

$$\bigl\|T(x)\bigr\|_\gamma \leqslant K|\xi| + K(\gamma)L\|x\|_\gamma \leqslant K|\xi| + K(\gamma)L\Delta \leqslant \Delta. \tag{27}$$

Next if x_1 and x_2 are in B, it follows by similar reasoning that

$$\bigl\|T(x_1) - T(x_2)\bigr\|_\gamma \leqslant K(\gamma)L\|x_1 - x_2\|_\gamma. \tag{28}$$

Since $K(\gamma)L < 1$, T is a contraction and so has a unique fixed point $x(t)$. That $x(t) = 0$ when $\xi = 0$ follows by uniqueness and the inequality (26) follows from (27) by putting $Tx = x$.

To prove the smoothness, we write $T(x)$ as $T(x, \xi, \mu)$ to indicate the dependence on ξ and μ. Note that if $x \in B$

$$\begin{aligned} T(x, \xi, \mu)(t) = X(t)\xi &+ \int_0^t X(t)P_+X^{-1}(s)h\bigl(s, x(s), \mu\bigr)\,\mathrm{d}s \\ &- \int_t^\infty X(t)(I - P_+)X^{-1}(s)h\bigl(s, x(s), \mu\bigr)\,\mathrm{d}s. \end{aligned} \tag{29}$$

It is not hard to see that for $1 \leqslant m + p + q \leqslant r$, $p \geqslant 1$, the partial derivatives are given by the formulae

$$\bigl(T_\xi(x, \xi, \mu)\xi_1\bigr)(t) = X(t)\xi_1, \quad p = 1,\ m + q = 0,$$

$$T_{x^m\xi^p\mu^q}(x, \xi, \mu) = 0, \quad p = 1,\ m + q \geqslant 1 \text{ or } p \geqslant 2$$

and for $p = 0$, $1 \leqslant m + q \leqslant r$ by

$$\begin{aligned}&\big(T_{x^m\mu^q}(x,\xi,\mu)u_1\cdots u_m\big)(t)\\&\quad= \int_0^t X(t)P_+X^{-1}(s)h_{x^m\mu^q}\big(s,x(s),\mu\big)u_1(s)\cdots u_m(s)\,\mathrm{d}s\\&\qquad - \int_t^\infty X(t)(I-P_+)X^{-1}(s)h_{x^m\mu^q}\big(s,x(s),\mu\big)u_1(s)\cdots u_m(s)\,\mathrm{d}s,\end{aligned}$$

where we use the notation $T_{x^m\xi^p\mu^q}$ for $\frac{\partial^{m+p+q}T}{\partial x^m\partial\xi^p\partial\mu^q}$, $\xi_1 \in \mathcal{R}(P_+)$ and $u_1, \ldots, u_m$ are in E. (Note when $m = 0$ and $q = r$, we use the facts that $h(t, 0, \mu) = 0$ and the boundedness of the derivatives of h to verify that this formula yields the derivative.) These derivatives are also continuous functions of (x, ξ, μ) for $x \in B$, $\xi \in \mathcal{R}(P_+)$ satisfying (25) and μ in $|\mu| < \mu_0$. Thus $(x, \xi, \mu) \mapsto T(x, \xi, \mu)$ is a C^r map. Now we use the following well-known lemma:

LEMMA 3.8. *Let B be a closed ball in a Banach space E and let V be an open set in another Banach space Λ. Suppose $T : B \times V \mapsto B$ is a mapping such that for all x_1, $x_2 \in B$ and $\lambda \in V$*

$$\big\|T(x_1,\lambda) - T(x_2,\lambda)\big\| \leqslant \sigma\|x_1 - x_2\|$$

where $0 \leqslant \sigma < 1$. Then for each $\lambda \in V$ the equation

$$T(x,\lambda) = x$$

has a unique solution $x = x(\lambda)$ in B. Moreover, if T is C^r $(0 \leqslant r \leqslant \infty)$, then so also is $x(\lambda)$, and the derivative $Dx(\lambda)$ satisfies the equation

$$Dx(\lambda) = \frac{\partial T}{\partial x}\big(x(\lambda),\lambda\big)Dx(\lambda) + \frac{\partial T}{\partial\lambda}\big(x(\lambda),\lambda\big).$$

(*Note*: *T is C^r means that T is defined and C^r in an open set containing $B \times V$.*)

We apply this lemma with V as the set of $(\xi, \mu) \in \Lambda = \mathcal{R}(P_+) \times \mathbf{R}$ satisfying (25) and $|\mu| < \mu_0$ and with $T(x, \xi, \mu)$ as defined in (29). In view of (28), we can take $\sigma = K(\gamma)L$. This means $x(\xi, \mu)$ defined by $x(\xi, \mu)(t) = x(t, \xi, \mu)$, which maps the (ξ, μ) space into the Banach space E is C^r.

In particular, since $x(\xi, \mu)$ is continuous as a function into E, it follows that $x(t, \xi, \mu)$ is continuous in (ξ, μ) uniformly with respect to t. Then since $x(t, \xi, \mu)$ is continuous in t for each fixed (ξ, μ), it follows that $x(t, \xi, \mu)$ is continuous in (t, ξ, μ).

Next, if $r \geqslant 1$, we know that

$$\sup_{t\geqslant 0} \mathrm{e}^{\gamma t}\big|x(t,\xi+\xi_1,\mu) - x(t,\xi,\mu) - \big(x_\xi(\xi,\mu)\xi_1\big)(t)\big| = \mathrm{o}\big(|\xi_1|\big)$$

as $\xi_1 \to 0$, where as follows from Lemma 3.8,

$$x_\xi(\xi,\mu) = T_x\big(x(\xi,\mu),\xi,\mu\big)x_\xi(\xi,\mu) + T_\xi\big(x(\xi,\mu),\xi,\mu\big)$$

so that, if we write $(x_\xi(\xi,\mu)\xi_1)(t) = Z(t)\xi_1$, we see that

$$\begin{aligned} Z(t)\xi_1 = X(t)\xi_1 &+ \int_0^t X(t)P_+X^{-1}(s)h_x\big(s,x(s,\xi,\mu),\mu\big)Z(s)\xi_1\,\mathrm{d}s \\ &- \int_t^\infty X(t)(I-P_+)X^{-1}(s)h_x\big(s,x(s,\xi,\mu),\mu\big)Z(s)\xi_1\,\mathrm{d}s. \end{aligned}$$

This means that $x_\xi(t,\xi,\mu)$ exists and equals $Z(t)$ restricted to $\mathcal{R}(P_+)$, where $Z(t)$ is the unique solution of

$$\dot{Z} = \big[A(t) + h_x\big(t,x(t,\xi,\mu),\mu\big)\big]Z$$

such that $\|Z\|_\gamma < \infty$ and $P_+Z(0) = P_+$. Moreover, since $x_\xi(\xi,\mu)$ is a continuous function of (ξ,μ), it follows that $x_\xi(t,\xi,\mu)$ is a continuous function of (ξ,μ), uniformly with respect to t. Since $x_\xi(t,\xi,\mu)$ is continuous in t for each fixed (ξ,μ), it follows that $x_\xi(t,\xi,\mu)$ is continuous in (t,ξ,μ). Furthermore from the equation for $Z(t)$ above and Lemma 3.6, we have the estimate

$$\|Z\|_\gamma \leqslant K + K(\gamma)L\|Z\|_\gamma$$

so that for $t \geqslant 0$

$$\big|x_\xi(t,\xi,\mu)\big| \leqslant \big(1-K(\gamma)L\big)^{-1}K\mathrm{e}^{-\gamma t}.$$

Also, since $h(t,0,0) = 0$, we see that

$$x_\xi(t,0,0) = X(t)P_+.$$

Similarly, we show that $x_\mu(t,\xi,\mu)$ is the unique solution of

$$\dot{x} = \big[A(t) + h_x\big(t,x(t,\xi,\mu),\mu\big)\big]x + h_\mu\big(t,x(t,\xi,\mu),\mu\big)$$

such that $\|x\|_\gamma < \infty$ and $P_+x(0) = 0$ and, if $r \geqslant 2$, that $x_{\xi\xi}(t,\xi,\mu)$ is the unique solution restricted to $\mathcal{R}(P_+) \times \mathcal{R}(P_+)$ of

$$\dot{Z} = \big[A(t) + h_x\big(t,x(t,\xi,\mu),\mu\big)\big]Z + h_{xx}\big(t,x(t,\xi,\mu),\mu\big)x_\xi(t,\xi,\mu)x_\xi(t,\xi,\mu)$$

such that $\|Z\|_\gamma < \infty$ and $P_+Z(0) = 0$. Also we get the required estimates from Lemma 3.6. Thus we complete the proof of Lemma 3.7. □

We apply Lemma 3.7 to Eq. (22). Suppose Δ satisfies

$$K(\gamma)\delta(\Delta,0) = K\big[(\alpha-\gamma)^{-1} + 2\gamma^{-1}\big]\delta(\Delta,0) < 1.$$

Then we take μ_0 as the smallest μ such that

$$K(\gamma)\delta(\Delta,\mu) = 1$$

and set

$$\xi_0 = K^{-1}\big(1 - K(\gamma)L\big)\Delta.$$

Then, using Lemma 3.7, if $|\mu| < \mu_0$ and if $\xi \in \mathcal{R}(P_+)$ with $|\xi| < \xi_0$, we get a unique solution $z(t) = z(t,\xi,\mu)$ of (22) with $P_+z(0) = \xi$ and $\|z\|_\gamma \leqslant \Delta$. Then we define

$$x^+(t,\xi,\mu) = u(t,\mu) + z(t,\xi,\mu)$$

and we see that (iii) and hence Proposition 3.5 has been proved. □

Similarly we find the local unstable manifold near $u(0,\mu)$ with asymptotic phase 0, that is, we find the solutions $x(t)$ with $x(0)$ near $u(0,\mu)$ such that $|x(t) - u(t,\mu)| \to 0$ as $t \to -\infty$. We state the proposition without proof as it is similar to that of Proposition 3.5.

PROPOSITION 3.9. *As in Proposition* 3.5, *let the function* $f(x,\mu)$ *be* C^{r+2} $(r \geqslant 0)$ *and suppose*

$$\dot{x} = f(x,0)$$

has a hyperbolic T*-periodic solution* $u_0(t)$. *Then* (i) *and* (ii) *hold as in Proposition* 3.5. *Next suppose* $0 < \gamma < \alpha$. *Then for* $\Delta > 0$ *sufficiently small, there are positive numbers* μ_0, η_0 *depending on* Δ *such that if* $|\mu| < \mu_0$ *and* $\eta \in \mathcal{R}(P_-)$ *satisfies* $|\eta| < \eta_0$, *there exists a unique solution* $x(t) = x^-(t,\eta,\mu)$ *of* (20) *such that*

$$\big|x(t) - u(t,\mu)\big|e^{-\gamma t} \leqslant \Delta \quad (t \leqslant 0), \qquad P_-\big[x(0) - u(0,\mu)\big] = \eta.$$

Moreover,

$$x^-(t,0,\mu) = u(t,\mu),$$

$x^-(t,\xi,\mu)$ *is* C^r *in its arguments with* $x^-_\eta(t,\eta,\mu)$ *as the unique solution restricted to* $\mathcal{R}(P_-)$ *of*

$$\dot{Z} = f_x\big(x^+(t,\eta,\mu),\mu\big)Z$$

such that $\sup_{t\leqslant 0} e^{-\gamma t}|Z(t)| < \infty$ *and* $P_-Z(0) = P_-$ *with, in particular,*

$$x^-_\eta(t,0,0) = X(t)P_-$$

and there is a constant N such that when $r \geqslant 1$,

$$\left|x_\eta^-(t,\eta,\mu)\right| \leqslant N\mathrm{e}^{\gamma t}, \quad \left|x_\mu^-(t,\xi,\mu) - u_\mu(t,\mu)\right| \leqslant N\mathrm{e}^{\gamma t} \quad (t \leqslant 0)$$

and when $r \geqslant 2$,

$$\left|x_{\eta\eta}^-(t,\eta,\mu)\right| \leqslant N\mathrm{e}^{\gamma t} \quad (t \leqslant 0).$$

REMARK 3.10. It is clear from the proof that when $f(x,\mu)$ does not depend on μ the relevant conclusions of Propositions 3.5 and 3.9 hold under the weaker assumption that $f(x)$ is C^r $(r \geqslant 1)$.

3.3. *Global stable and unstable manifolds and asymptotic phase*

Consider now the system

$$\dot{x} = f(x), \tag{30}$$

with flow ϕ^t, where f is C^r $(r \geqslant 1)$ with $|f(x)| \leqslant M_0$ and $|f'(x)| \leqslant M_1$ for all $x \in \mathbf{R}^n$. We suppose the system has a hyperbolic periodic orbit $u_0(t)$ with minimal period T.

From Proposition 3.5(i), we know that

$$\dot{x} = f'\big(u_0(t)\big)x$$

has a trichotomy with projections P_0, P_+, P_- and constants K, α, where α can be any positive number such that $|\lambda| > \mathrm{e}^{\alpha T}$ for all Floquet multipliers λ with $|\lambda| > 1$ and $|\lambda| < \mathrm{e}^{-\alpha T}$ for those with $|\lambda| < 1$.

Also, given γ such that $0 < \gamma < \alpha$, there exist $\Delta > 0$ and ξ_0 such that if $\xi \in \mathcal{R}(P_+)$ with $|\xi| < \xi_0$ then (30) has a unique solution $x(t) = x^+(t,\xi)$ such that

$$\left|x(t) - u_0(t)\right| \leqslant \Delta\mathrm{e}^{-\gamma t} \quad \text{for } t \geqslant 0, \qquad P_+\big[x(0) - u_0(0)\big] = \xi.$$

Moreover, in view of Remark 3.10, $x_\xi^+(t,\xi)$ exists, is continuous and is the unique solution restricted to $\mathcal{R}(P_+)$ of

$$\dot{Z} = f'\big(x^+(t,\xi)\big)Z \tag{31}$$

such that $\|Z\|_\gamma < \infty$ and $P_+Z(0) = P_+$.

Similarly, if $\eta \in \mathcal{R}(P_-)$ with $|\eta| < \eta_0$ then (30) has a unique solution $x(t) = x^-(t,\eta)$ such that

$$\left|x(t) - u_0(t)\right| \leqslant \Delta\mathrm{e}^{\gamma t} \quad \text{for } t \leqslant 0, \qquad P_-\big[x(0) - u_0(0)\big] = \eta.$$

Moreover $x_\eta^-(t,\eta)$ exists, is continuous and is the unique solution restricted to $\mathcal{R}(P_-)$ of

$$\dot{Z} = f'\bigl(x^-(t,\eta)\bigr)Z$$

such that $\sup_{t\leqslant 0}|Z(t)|e^{-\gamma t} < \infty$ and $P_-Z(0) = P_-$.

Note that $x^+(t,\xi)$ (resp. $x_-(t,\eta)$) can be continued backwards (resp. forwards) so as to be defined for all t.

Now we define the global stable and unstable manifolds.

DEFINITION 3.11. The *global stable manifold* is defined as

$$W^s(u_0) = \bigl\{x \in \mathbf{R}^n\colon\ \operatorname{dist}\bigl(\phi^t(x), u_0(\cdot)\bigr) \to 0 \text{ as } t \to \infty\bigr\}$$

and the *global unstable manifold* as

$$W^u(u_0) = \bigl\{x \in \mathbf{R}^n\colon\ \operatorname{dist}\bigl(\phi^t(x), u_0(\cdot)\bigr) \to 0 \text{ as } t \to -\infty\bigr\},$$

where

$$\operatorname{dist}\bigl(y, u_0(\cdot)\bigr) = \min_{0\leqslant t\leqslant T}\bigl|y - u_0(t)\bigr|.$$

In the next proposition, we show that the global stable and unstable manifolds can be defined in terms of the functions $x^+(t,\xi)$ and $x^-(t,\eta)$.

PROPOSITION 3.12. $x \in W^s(u_0)$ *if and only if there exists* γ^+ *and* ξ *such that*

$$\phi^t(x) = x^+(t+\gamma^+,\xi)$$

for all t. *This* γ^+ *has the property that* $|\phi^t(x) - u_0(t+\gamma^+)| \to 0$ *as* $t \to \infty$ *and is called the* (*forward*) *asymptotic phase of* x. *It is unique up to a multiple of* T. *It also follows that*

$$W^s(u_0) = \bigl\{x^+(t,\xi)\colon\ -\infty < t < \infty, |\xi| < \xi_0\bigr\}$$

and is an immersed submanifold of $\mathbf{R}^n$. *Moreover, if* $x \in W^s(u_0)$, *then*

$$T_xW^s(u_0) = \Bigl\{\xi \in \mathbf{R}^n\colon\ \sup_{t\geqslant 0}\bigl|D\phi^t(x)\xi\bigr| < \infty\Bigr\}.$$

PROOF. Denote by C the hyperplane passing through $u_0(0)$ and orthogonal to $f(u_0(0))$. We choose an open neighbourhood N of $u_0(0)$ in C with the following properties:

(a) $|f(x) - f(u_0(0))| < |f(u_0(0))|$ if $x \in N$;

(b) the Poincaré map $P: N \to P(N) \subset C$ associated with the cross-section C as in Proposition 3.4 is a well-defined C^1 diffeomorphism such that

$$P(x) = \phi^{\tau(x)}(x) \quad \text{with } \bigl|\tau(x) - T\bigr| \leqslant T/2$$

and

$$\phi^t(x) \notin N \quad \text{if } 0 < t < \tau(x);$$

(c) there exists a constant L such that if $P^k(x) \in N$ for $k \geqslant 0$, then $|P^k(x) - u_0(0)| \leqslant Le^{-k\gamma T}|x - u_0(0)|$ for $k \geqslant 0$.

(c) can be arranged by Proposition 1.8 in [19, p. 5], since the eigenvalues λ of $DP(0)$ satisfy $|\lambda| > e^{\alpha T} > e^{\gamma T}$ if $|\lambda| > 1$ and $|\lambda| < e^{-\alpha T} < e^{-\gamma T}$ if $|\lambda| < 1$. Later another condition will be added to N.

Now consider the intersections of the orbit $x(t) = \phi^t(x)$ with N. By (a) the tangent vector $\dot{x}(t) = f(x(t))$ is transverse to C when $x(t) \in N$ and so the set $\{t\colon x(t) \in N\}$ is isolated. It follows from (b) and the fact that

$$\operatorname{dist}\bigl(x(t), u_0(\cdot)\bigr) \to 0$$

as $t \to \infty$ that the set $\{t \geqslant 0\colon x(t) \in N\}$ is an increasing sequence $\{t_k\}_{k=0}^{\infty}$, where $t_k \to \infty$ as $k \to \infty$, and there is a positive integer k_0 such that

$$x(t_{k+1}) = P\bigl(x(t_k)\bigr)$$

for $k \geqslant k_0$. Then from (c) it follows that

$$\bigl|x(t_k) - u_0(0)\bigr| \leqslant Le^{-\gamma(k-k_0)T}\bigl|x(t_{k_0}) - u_0(0)\bigr|$$

for $k \geqslant k_0$.

Now we define

$$s_k = t_k - kT$$

so that for $k \geqslant k_0$

$$\begin{aligned} |s_{k+1} - s_k| &= |t_{k+1} - t_k - T| \\ &= \bigl|\tau\bigl(x(t_k)\bigr) - \tau\bigl(u_0(0)\bigr)\bigr| \\ &\leqslant L_1 L\bigl|x(t_{k_0}) - u_0(0)\bigr|e^{-\gamma(k-k_0)T}, \end{aligned}$$

where L_1 is a Lipschitz constant for $\tau(x)$ in N. It follows that s_k is a Cauchy sequence. Let the limit be $-\gamma_1$. Then if $k \geqslant k_0$

$$|s_k + \gamma_1| = \left|\sum_{\ell=k+1}^{\infty}(s_\ell - s_{\ell-1})\right| \leqslant L_2\bigl|x(t_{k_0}) - u_0(0)\bigr|e^{-\gamma(k-k_0)T},$$

where

$$L_2 = L_1 L(1 - e^{-\gamma T})^{-1}.$$

Now it follows from Gronwall's lemma that

$$\left|x(t) - u_0(t+\beta)\right| \leqslant e^{M_1|t-s|}\left|x(s) - u_0(s+\beta)\right|$$

for all t, s and β. Then if $k \geqslant k_0$

$$\begin{aligned}\left|x(kT-\gamma_1) - u_0(0)\right| &\leqslant e^{M_1|s_k+\gamma_1|}\left|x(t_k) - u_0(s_k+\gamma_1)\right| \\ &\leqslant e^{M_1|s_k+\gamma_1|}\left[\left|x(t_k) - u_0(0)\right| + \left|u_0(0) - u_0(s_k+\gamma_1)\right|\right] \\ &\leqslant e^{M_1|s_k+\gamma_1|}\left[\left|x(t_k) - u_0(0)\right| + M_0|s_k+\gamma_1|\right] \\ &\leqslant e^{M_1|s_k+\gamma_1|}[L + M_0L_2]\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma(k-k_0)T} \\ &\leqslant L_3\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma kT},\end{aligned}$$

where

$$L_3 = e^{M_1L_2|x(t_{k_0})-u_0(0)|}[L + M_0L_2]e^{\gamma k_0T}.$$

Suppose now $t \geqslant k_0T - \gamma_1$. Then there exists $k \geqslant k_0$ such that

$$kT - \gamma_1 \leqslant t < (k+1)T - \gamma_1.$$

Then

$$\begin{aligned}\left|x(t) - u_0(t+\gamma_1)\right| &\leqslant e^{M_1(t-kT+\gamma_1)}\left|x(kT-\gamma_1) - u_0(kT)\right| \\ &= e^{M_1(t-kT+\gamma_1)}\left|x(kT-\gamma_1) - u_0(0)\right| \\ &\leqslant e^{M_1T}L_3\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma kT} \\ &\leqslant e^{M_1T}L_3\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma(t-T+\gamma_1)}\end{aligned}$$

so that for $t \geqslant 0$

$$\begin{aligned}\left|x(t+k_0T-\gamma_1) - u_0(t)\right| &= \left|x(t+k_0T-\gamma_1) - u_0(t+k_0T)\right| \\ &\leqslant e^{M_1T}L_3\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma(t+(k_0-1)T)} \\ &= e^{(M_1-\gamma(k_0-1))T}L_3\left|x(t_{k_0}) - u_0(0)\right|e^{-\gamma t},\end{aligned}$$

where

$$e^{(M_1-\gamma(k_0-1))T}L_3 = e^{M_1L_2|x(t_{k_0})-u_0(0)|}[L + M_0L_2]e^{(M_1+\gamma)T}.$$

Then if N is also chosen so that for all $x \in N$

$$e^{M_1L_2|x-u_0(0)|}[L + M_0L_2]e^{(M_1+\gamma)T}\left|x - u_0(0)\right| < \min\{\Delta, K^{-1}\xi_0\},$$

it follows by uniqueness in Proposition 3.5 (see the remarks at the beginning of this subsection) that

$$x(t + k_0T - \gamma_1) = x^+(t, \xi),$$

with

$$\xi = P_+\bigl[x(k_0T - \gamma_1) - u_0(0)\bigr].$$

It follows that

$$x(t) = x^+(t + \gamma_1 - k_0T, \xi)$$

for $t \geqslant k_0T - \gamma_1$ and hence for all t. Taking $\gamma^+ = k_0T - \gamma_1$, this proves the first part of the proposition.

Now we examine the extent to which the asymptotic phase is unique. Suppose x has asymptotic phases γ_1 and γ_2. Then

$$\bigl|u(t + \gamma_1) - u(t + \gamma_2)\bigr| \to 0 \quad \text{as } t \to \infty. \tag{32}$$

Let

$$\gamma_1 = \bar{\gamma}_1 + k_1T, \qquad \gamma_2 = \bar{\gamma}_2 + k_2T$$

where $0 \leqslant \bar{\gamma}_1, \bar{\gamma}_2 < T$ and k_1, k_2 are integers. Then it follows from (32) that

$$\bigl|u(\bar{\gamma}_1) - u(\bar{\gamma}_2)\bigr| = \bigl|u\bigl((k - k_1)T + \gamma_1\bigr) - u\bigl((k - k_1)T + \gamma_2\bigr)\bigr| \to 0 \quad \text{as } k \to \infty.$$

That is, $u(\bar{\gamma}_1) = u(\bar{\gamma}_2)$ and so $\bar{\gamma}_1 = \bar{\gamma}_2$. Hence if γ_1, γ_2 are two asymptotic phases, $\gamma_1 - \gamma_2$ is a multiple of T. Conversely, it is obvious that if γ^+ is an asymptotic phase, then so also is $\gamma^+ + kT$ for any integer k.

It is clear from the first part of the proposition that

$$W^s(u_0) = \bigl\{x^+(t, \xi)\colon -\infty < t < \infty, |\xi| < \xi_0\bigr\}.$$

Now we know that $x_t^+(t, \xi) = f(x(t, \xi))$ is a solution of (31) bounded on $\mathcal{R}_+$ whose norm is bounded below by a positive number as $t \to \infty$ and $x(t) = x_\xi^+(t, \xi)\xi_1$ for $\xi_1 \in \mathcal{R}(P_+)$ is a solution $\to 0$ as $t \to \infty$ such that $P_+x(0) = \xi_1$. It follows that the matrix

$$\bigl[\, x_t^+(t, \xi) \quad x_\xi^+(t, \xi) \,\bigr]$$

is of full rank so that $(t, \xi) \mapsto x^+(t, \xi)$ is an immersion.

If $x = x^+(t, \xi) \in W^s(u_0)$, then we define the tangent space

$$T_xW^s(u_0) = \text{the range of } \bigl[\, x_t^+(t, \xi) \quad x_\xi^+(t, \xi) \,\bigr].$$

We show this is independent of (t,ξ) such that $x = x^{+}(t,\xi)$. Suppose

$$x = x^{+}(t_1,\xi_1) = x^{+}(t_2,\xi_2)$$

with $t_1 \geqslant t_2$. Then, for all t,

$$\phi^{t}(x) = x^{+}(t+t_1,\xi_1) = x^{+}(t+t_2,\xi_2) \tag{33}$$

so that t_1 and t_2 are both asymptotic phases for x. It follows that $t_1 = t_2 + kT$ for some nonnegative integer $k \geqslant 0$ and taking $t = -t_2$ in (33) we find that

$$x^{+}(0,\xi_2) = x^{+}(kT,\xi_1).$$

It follows that

$$\bigl|P_{+}\bigl[x^{+}(kT,\xi_1) - u_0(0)\bigr]\bigr| = \bigl|P_{+}\bigl[x^{+}(0,\xi_2) - u_0(0)\bigr]\bigr| = |\xi_2| < \xi_0$$

so that

$$\bigl|P_{+}\bigl[x^{+}(kT,\xi) - u_0(0)\bigr]\bigr| < \xi_0$$

if ξ is sufficiently close to ξ_1. Thus, by uniqueness in Proposition 3.5

$$x^{+}(t+kT,\xi) = x^{+}\bigl(t,\psi(\xi)\bigr)$$

for ξ close to ξ_1, where

$$\psi(\xi) = P_{+}\bigl[x^{+}(kT,\xi) - u_0(0)\bigr].$$

It follows that

$$x_t^{+}(t_1,\xi_1) = x_t^{+}(t_2+kT,\xi_1) = x_t^{+}\bigl(t_2,\psi(\xi_1)\bigr) = x_t^{+}(t_2,\xi_2)$$

and

$$\begin{aligned}
x_\xi^{+}(t_1,\xi_1) &= x_\xi^{+}(t_2+kT,\xi_1)\\
&= \frac{\partial}{\partial\xi} x^{+}\bigl(t_2,\psi(\xi)\bigr)\Big|_{\xi=\xi_1}\\
&= x_\xi^{+}\bigl(t_2,\psi(\xi_1)\bigr)\psi'(\xi_1)\\
&= x_\xi^{+}(t_2,\xi_2)\psi'(\xi_1),
\end{aligned}$$

which show that the range of the matrix $[\,x_t^{+}(t_1,\xi_1) \quad x_\xi^{+}(t_1,\xi_1)\,]$ is contained in and hence coincides with the range of $[\,x_t^{+}(t_2,\xi_2) \quad x_\xi^{+}(t_2,\xi_2)\,]$. So $T_x W^{s}(u_0)$ is well-defined.

Now, as we mentioned earlier, $Z(t) = x_\xi^+(t, \xi_1)$ is the unique solution restricted to $\mathcal{R}(P_+)$ of (31) with $\xi = \xi_1$ such that $\|Z\|_\gamma < \infty$ and $P_+Z(0) = P_+$. However, since $|f'(x^+(t, \xi_1)) - f'(u_0(t))| \to 0$ as $t \to \infty$, it follows from Remarks 2.7 and 2.3 that

$$\dot{y} = f'\bigl(x^+(t, \xi_1)\bigr)y \tag{34}$$

has a trichotomy on $[t_1, \infty)$ with projections having the same rank as those for $\dot{x} = f'(u_0(t))x$. So this equation has a subspace W_t of solutions bounded on $[t_1, \infty)$ with dimension equal to $\operatorname{rank}(P_0 + P_+)$. It follows that

$$\operatorname{span}\bigl\{f(x^+(t, \xi_1)\bigr\} \oplus \mathcal{R}\bigl(x_\xi^+(t, \xi_1)\bigr),$$

which has dimension equal to $\operatorname{rank}(P_0 + P_+)$, coincides with W_t. Next note that (34) can be written as $\dot{y} = f'(\phi^{t-t_1}(x))y$. So, by a time shift, it follows that $\operatorname{span}\{f(x^+(t + t_1, \xi_1)\} \oplus \mathcal{R}(x_\xi^+(t + t_1, \xi_1))$ is the subspace of solutions of

$$\dot{y} = f'\bigl(\phi^t(x)\bigr)y \tag{35}$$

which are bounded on $[0, \infty)$. Hence

$$T_x W^s(u_0) = \operatorname{span}\bigl\{f\bigl(x^+(t_1, \xi_1)\bigr)\bigr\} \oplus \mathcal{R}\bigl(x_\xi^+(t_1, \xi_1)\bigr)$$

consists of the values at $t = 0$ of the subspace of solutions of (35) which are bounded on $[0, \infty)$, that is,

$$\Bigl\{\xi \in \mathbf{R}^n\colon \sup_{t \geqslant 0}\bigl|D\phi^t(x)\xi\bigr| < \infty\Bigr\}.$$

This completes the proof of the proposition. □

Similarly, we can prove the following proposition.

PROPOSITION 3.13. *$x \in W^u(u_0)$ if and only if there exists γ^- and η such that*

$$\phi^t(x) = x^-(t + \gamma^-, \eta)$$

for all t. This γ^- has the property that $|\phi^t(x) - u_0(t + \gamma^-)| \to 0$ as $t \to -\infty$ and is called the (*backward*) *asymptotic phase of x. It is unique up to a multiple of T. It also follows that*

$$W^u(u_0) = \bigl\{x^-(t, \eta)\colon -\infty < t < \infty, |\eta| < \eta_0\bigr\}$$

and is an immersed submanifold of $\mathbf{R}^n$. Moreover, if $x \in W^u(u_0)$, then

$$T_x W^u(u_0) = \Bigl\{\eta \in \mathbf{R}^n\colon \sup_{t \leqslant 0}\bigl|D\phi^t(x)\eta\bigr| < \infty\Bigr\}.$$

Finally we define the local stable and unstable fibres.

DEFINITION 3.14. Corresponding to γ^+ in $0 \leqslant \gamma^+ < T$, we define the *local stable fibre*:

$$W_{\mathrm{loc}}^{s,\gamma^+}(u_0) = \bigl\{x^+(\gamma^+, \xi)\colon\ \xi \in \mathcal{R}(P_+),\ |\xi| < \xi_0\bigr\}$$

and we define the *global stable fibre* $W^{s,\gamma^+}(u_0)$ as

$$\bigcup_{m\in Z} \phi^{mT}\bigl(W_{\mathrm{loc}}^{s,\gamma^+}(u_0)\bigr) = \bigl\{x^+(\gamma^+ + mT, \xi)\colon\ \xi \in \mathcal{R}(P_+), |\xi| < \xi_0, m \in Z\bigr\}.$$

It is easy to see that $x \in W^{s,\gamma^+}(u_0)$ if and only if $|\phi^t(x) - u_0(t + \gamma^+)| \to 0$ as $t \to \infty$ and that

$$W^s(u_0) = \bigcup_{0\leqslant\gamma^+<T} W^{s,\gamma^+}(u_0).$$

DEFINITION 3.15. Corresponding to γ^- in $0 \leqslant \gamma^- < T$, we define the *local unstable fibre*:

$$W_{\mathrm{loc}}^{u,\gamma^-}(u_0) = \bigl\{x^-(\gamma^-, \eta)\colon\ \eta \in \mathcal{R}(P_-), |\eta| < \eta_0\bigr\}$$

and we define the *global unstable fibre* $W^{u,\gamma^-}(u_0)$ as

$$\bigcup_{m\in Z} \phi^{mT}\bigl(W_{\mathrm{loc}}^{u,\gamma^-}(u_0)\bigr) = \bigl\{x^-(\gamma^- + mT, \eta)\colon\ \eta \in \mathcal{R}(P_-), |\eta| < \eta_0, m \in Z\bigr\}.$$

It is easy to see that $x \in W^{u,\gamma^-}(u_0)$ if and only if $|\phi^t(x) - u_0(t + \gamma^-)| \to 0$ as $t \to -\infty$ and that

$$W^u(u_0) = \bigcup_{0\leqslant\gamma^-<T} W^{u,\gamma^-}(u_0).$$

4. Homoclinic orbits

In this section we study properties of periodic-to-periodic homoclinic orbits. First we define a Poincaré map associated with such an orbit. Then we give equivalent conditions for transversality of the periodic-to-periodic homoclinic orbits including its equivalence with the transversality of the corresponding homoclinic orbit of the Poincaré map. Then Smale's theorem enables us to deduce the existence of chaotic behaviour in the neighbourhood of a transversal periodic-to-periodic homoclinic orbit.

So let $u_0(t)$ be a hyperbolic T-periodic orbit of the C^1 system

$$\dot{x} = f(x), \tag{36}$$

where, as usual, we assume that $|f(x)| \leqslant M_0$ and $|f'(x)| \leqslant M_1$. We make the following definition.

DEFINITION 4.1. If $u_0(t)$ is a hyperbolic T-periodic orbit of (36), then a solution $p(t)$ is said to be a *homoclinic orbit* if dist $(p(t), u_0(\cdot)) \to 0$ as $|t| \to \infty$ or, equivalently, $p(t) \in W^s(u_0) \cap W^u(u_0)$.

4.1. *Poincaré map associated with a homoclinic orbit*

Consider system (36) with hyperbolic T-periodic orbit $u_0(t)$ and associated homoclinic orbit $p(t)$. Denote by C the hyperplane passing through $u_0(0)$ and orthogonal to $f(u_0(0))$. In a neighbourhood of $u_0(0)$ in C, we will define a map F which has $u_0(0)$ as a hyperbolic fixed point and an associated homoclinic orbit which consists of points on the solution $p(t)$ which lie on C.

First we choose an open neighbourhood N of $u_0(0)$ in C with the following properties:

(a) $|f(y) - f(u_0(0))| \leqslant \frac{1}{2}|f(u_0(0))|$ if $y \in N$;

(b) the Poincaré map $P : N \mapsto C$ (see Proposition 3.4) has the properties that for $x \in N$

$$\phi^t(x) \notin N \quad \text{if } 0 < t < \tau_0(x)$$

and

$$\left|\tau_0(x) - T\right| \leqslant T/2,$$

where $P(x) = \phi^{\tau_0(x)}(x)$;

(c) $P^k(x) \in N$ for all integers k if and only if $x = u_0(0)$.

That N can be chosen so that (c) is satisfied follows from the fact that $u_0(0)$ is an isolated invariant set for P (see [19, p. 44]).

Consider the intersections of the homoclinic orbit $p(t)$ with N. Similarly to the beginning of the proof of Proposition 3.12, it follows that the set $\{t \in \mathbf{R}\colon\ p(t) \in N\}$ is an increasing sequence $\{t_k\}_{k=-\infty}^{\infty}$, where $t_k \to \pm\infty$ as $k \to \pm\infty$ and

$$p(t_{k+1}) = P\big(p(t_k)\big)$$

if $|k|$ is sufficiently large. It is also clear that $p(t_k) \to u_0(0)$ as $k \to \pm\infty$. For short, we write

$$p_k = p(t_k).$$

Because of property (c) of P, there exists an integer K^- such that

$$p_{k+1} = P(p_k) \quad \text{if } k < K^-$$

but

$$P(p_{K^-}) \neq p_{K^-+1}.$$

We set

$$v_1 = P(p_{K^-}).$$

It follows from (b) that $\phi^t(p_{K^-}) \notin N$ if $0 < t < \tau_0(p_{K^-})$ and so if v_1 were in N, we would have $v_1 = p_{K^-+1}$. So $v_1 \notin N$.

Next we take K^+ to be an integer greater than K^- such that $p_{k+1} = P(p_k)$ if $k \geqslant K^+$. Then we set

$$v_2 = p_{K^+} = \phi^{T_1}(v_1).$$

Now consider the subset

$$I_0 = \{\dots, p_{K^--1}, p_{K^-}\} \cup \bigl\{u(0)\bigr\} \cup \{p_{K^++1}, p_{K^++2}, \dots\}$$

of N and choose an open neighbourhood $V_2 \subset N$ of $v_2 = p_{K^+}$ such that the closure of V_2 does not intersect $I_0 \cup \{v_1\}$. Then we can choose an open neighbourhood $V_0 \subset N$ of I_0 such that v_1 is not in the closure of V_0 and $P(V_0)$ does not intersect V_2.

Next we let $V_1 \subset C$ be an open ball with centre v_1 such that $V_0 \cap V_1$ is empty and the Poincaré map $Q = P(v_1, 0, T_1, v, v)$ with $v = u_0'(0)/|u_0'(0)|$ is defined on V_1, has range in V_2 and satisfies $|\tau_1(x) - T_1| \leqslant T_1/2$, where $Q(x) = \phi^{\tau_1(x)}(x)$. Note that $Q(v_1) = \phi^{T_1}(v_1) = v_2 = p_{K^+}$.

Now we define a diffeomorphism $F : V_0 \cup V_1 \mapsto C$ by

$$F(x) = \begin{cases} P(x) & \text{if } x \in V_0, \\ Q(x) & \text{if } x \in V_1. \end{cases}$$

F is well-defined since $V_0 \cap V_1$ is empty and is one to one since

$$P(V_0) \cap Q(V_1) \subset P(V_0) \cap V_2,$$

which is empty, and it is a diffeomorphism on to an open set since P and Q are diffeomorphisms. Since $u_0(0)$ is a hyperbolic fixed point for P, it is also a hyperbolic fixed point for F. Next we see that

$$\bigl\{\dots, p_{K^--1}, p_{K^-}, v_1 = P(p_{K^-}), v_2 = Q(v_1) = p_{K^+}, p_{K^++1}, p_{K^++2}, \dots\bigr\}$$

is a homoclinic orbit to $u_0(0)$.

4.2. *Transversal periodic-to-periodic homoclinic orbits and hyperbolicity*

We now define the notion of transversality for a periodic-to-periodic homoclinic orbit and show it is equivalent to hyperbolicity and also to transversality of the corresponding homoclinic orbit of the Poincaré map defined in the previous subsection.

DEFINITION 4.2. A homoclinic orbit $p(t)$ of (36) is said to be *transversal* if the tangent spaces $T_{p(t)}W^s(u_0)$ and $T_{p(t)}W^u(u_0)$ intersect in the subspace spanned by $p'(t) = f(p(t))$.

DEFINITION 4.3. A bounded solution $p(t)$ of (36) is said to be *hyperbolic* if $|f(p(t))|$ is bounded below by a positive number and there is a splitting

$$\mathbf{R}^n = \operatorname{span}\{f(p(t))\} \oplus E^s_{p(t)} \oplus E^u_{p(t)} \quad \text{for } t \in \mathbf{R}$$

with the invariance property

$$D\phi^\tau(p(t))(E^s_{p(t)}) = E^s_{p(t+\tau)}, \quad D\phi^\tau(p(t))(E^u_{p(t)}) = E^u_{p(t+\tau)}, \quad \text{for } \tau, t \in \mathbf{R},$$

and there are positive constants K and α such that for all t and $\tau \geqslant 0$

$$|D\phi^\tau(p(t))\xi| \leqslant K\mathrm{e}^{-\alpha\tau}|\xi|, \quad \xi \in E^s_{p(t)},$$

and

$$|D\phi^{-\tau}(p(t))\xi| \leqslant K\mathrm{e}^{-\alpha\tau}|\xi|, \quad \xi \in E^u_{p(t)}.$$

Note that a periodic solution is hyperbolic in the sense of Definition 3.3 if and only if it is hyperbolic in the sense of Definition 4.3 (see, for example, [19]). Now we give equivalent conditions for transversality of a periodic-to-periodic homoclinic orbit.

PROPOSITION 4.4. *Suppose $u_0(t)$ is a hyperbolic T-periodic orbit of* (36) *and $p(t)$ is an associated homoclinic orbit. Then the following conditions are equivalent*:

(i) *$p(t)$ is transversal*;
(ii) *$p(t)$ is hyperbolic*;
(iii) *$p'(t)$ is, up to a scalar multiple, the unique bounded solution of*

$$\dot{x} = f'(p(t))x; \tag{37}$$

(iv) *the variational system* (37) *has a trichotomy on* $\mathbf{R}$;
(v) *the corresponding homoclinic orbit of the associated Poincaré map F is transversal.*

PROOF. Note that by Proposition 3.12, $T_{p(t)}W^s(u_0)$ is the subspace of solutions of (37) bounded on $[0, \infty)$ and by Proposition 3.13, $T_{p(t)}W^u(u_0)$ is the subspace of solutions of

(37) bounded on $(-\infty, 0]$. Hence their intersection is the subspace of solutions of (37) bounded on $(-\infty, \infty)$. It follows at once that (i) and (iii) are equivalent.

By Remark 2.4, (iv) implies (iii). To prove that (iii) implies (iv), let γ^+ and γ^- be the forward and backward asymptotic phases of $p(0)$ so that $|p(t) - u_0(t + \gamma^+)| \to 0$ as $t \to \infty$ and $|p(t) - u_0(t + \gamma^-)| \to 0$ as $t \to -\infty$. Then since $\dot{x} = f'(u_0(t))x$ has a trichotomy on $\mathbf{R}$, it follows from Remarks 2.7 and 2.3 that (37) has trichotomies on both half-lines with projections of the same rank. By Remark 2.4 this together with (iii) implies (iv). So (iii) and (iv) are equivalent.

To show that (iv) and (v) are equivalent, we apply Proposition 2.9 to (37). Note that $|f'(p(t))| \leqslant M_1$ and $p'(t) = f(p(t))$ is a bounded solution of (37) such that $\inf|p'(t)| > 0$ since $\operatorname{dist}(p(t), u_0(\cdot)) \to 0$ as $|t| \to \infty$. Now, as in 4.1, the corresponding homoclinic orbit of the Poincaré map F can be written as a sequence $p(s_k)$ where $p(s_{-1}) = p_{K^-}$, $p(s_0) = v_1 = P(p_{K^-})$, $p(s_1) = v_2 = p_{K^+}$, etc., where we see from the properties of $\tau_0(x)$ and $\tau_1(x)$ that $T/2 \leqslant s_{k+1} - s_k \leqslant 3T/2$ if $k \neq 0$ and $s_1 - s_0 > 0$. So

$$0 < \inf(s_{k+1} - s_k) \leqslant \sup(s_{k+1} - s_k) < \infty.$$

We define the projection Q_k to be the projection with range W, the orthogonal complement of $\dot{u}_0(0) = f(u_0(0))$, and nullspace spanned by $f(p(s_k))$. Since $f(p(s_k)) \to f(u_0(0))$ as $|k| \to \infty$, Q_k converges as $|k| \to \infty$ to an orthogonal projection and so $|Q_k|$ is bounded. Next we see from the definition of F and (19) that

$$DF\big(p(s_k)\big) = Q_k D\phi^{s_{k+1}-s_k}\big(p(s_k)\big) = Q_k X(s_{k+1}) X^{-1}(s_k),$$

where $X(t) = D\phi^t(p(0))$ is the fundamental matrix of (37) with $X(0) = I$.

Then it follows from Proposition 2.9 that (37) has a trichotomy on $\mathbf{R}$ if and only if the difference equation

$$u_{k+1} = DF\big(p(s_k)\big)u_k, \quad u_k \in W,$$

has an exponential dichotomy on Z. However, this last statement is equivalent to the statement that $\{p(s_k)\}_{k=-\infty}^{\infty}$ is a transversal homoclinic orbit for F (see [19]). So (iv) and (v) are equivalent.

If (iv) holds, then there exist supplementary projections P_0, P_+, P_- with rank $P_0 = 1$ and positive constants K, α such that

$$\begin{aligned} &\big|X(t)P_0X^{-1}(s)\big| \leqslant K \quad \text{for all } t, s,\\ &\big|X(t)P_+X^{-1}(s)\big| \leqslant K\mathrm{e}^{-\alpha(t-s)} \quad \text{for } t \geqslant s,\\ &\big|X(t)P_-X^{-1}(s)\big| \leqslant K\mathrm{e}^{-\alpha(s-t)} \quad \text{for } t \leqslant s, \end{aligned}$$

where $X(t) = D\phi^t(p(0))$. The last two inequalities can be rewritten as

$$\begin{aligned} &\big|D\phi^\tau\big(p(s)\big)P_+(s)\big| \leqslant K\mathrm{e}^{-\alpha\tau} \quad \text{for } \tau \geqslant 0,\\ &\big|D\phi^{-\tau}\big(p(s)\big)P_-(s)\big| \leqslant K\mathrm{e}^{-\alpha\tau} \quad \text{for } \tau \geqslant 0, \end{aligned}$$

where $P_\sigma(t) = X(t)P_\sigma X^{-1}(t)$. Note also since $p'(t)$ is a bounded solution of (37), it follows that the range of $P_0(t)$ is spanned by $p'(t) = f(p(t))$. Note also, as observed above, that $\inf|p'(t)| > 0$. Hence if we define $E^s_{p(t)} = \mathcal{R}(P_+(t))$ and $E^u_{p(t)} = \mathcal{R}(P_-(t))$, we see that $p(t)$ is hyperbolic. Thus (iv) implies (ii).

If (ii) holds, then any solution $x(t)$ of (37) can be written as $x(t) = \lambda p'(t) + x_+(t) + x_-(t)$, where $x_\sigma(t) \in E^\sigma_{p(t)}$. If $x_+(t) \neq 0$, then $|x_+(t)| \to \infty$ as $t \to -\infty$ whereas $p'(t) + x_-(t)$ is bounded so that $|x(t)| \to \infty$. Hence, if $x(t)$ is bounded, we must have $x_+(t) = 0$. Similarly, $x_-(t) = 0$. So $x(t)$ is a multiple of $p'(t)$. Thus (ii) implies (iii) and the proof is completed. □

4.3. *Chaos near a transversal periodic-to-periodic homoclinic orbit*

In this subsection we examine the chaotic behaviour in the neighbourhood of a transversal periodic-to-periodic homoclinic orbit.

Consider system (36) with hyperbolic T-periodic orbit $u_0(t)$ and associated transversal homoclinic orbit $p(t)$. In the previous two subsections, we defined an associated Poincaré map F and showed that the sequence of points

$$\left\{\ldots, p_{K^- -1}, p_{K^-}, v_1 = P(p_{K^-}), v_2 = Q(v_1) = p_{K^+}, p_{K^+ +1}, p_{K^+ +2}, \ldots\right\}$$

is a transversal homoclinic orbit bi-asymptotic to the hyperbolic fixed point $u_0(0)$.

Now we prove the following

PROPOSITION 4.5. *Suppose system* (36) *has a hyperbolic T-periodic orbit $u_0(t)$ with associated transversal homoclinic orbit $p(t)$. Then there exists a compact invariant set $\mathcal{S}$ such that*

(a) *the periodic points are dense*;
(b) *there is a dense orbit*;
(c) *there exists $\delta > 0$ such that if x is in $\mathcal{S}$ there exists y in $\mathcal{S}$ arbitrarily close to x such that for any continuous nonnegative function $\alpha(t)$ with $\alpha(0) = 0$ there exists $t \geqslant 0$ with $|\phi^{\alpha(t)}(y) - \phi^t(x)| > \delta$.*

REMARK 4.6. (c) is sensitive dependence on initial conditions in the flow context. To the author's knowledge, there is no definition of sensitive dependence directly for flows in the literature since usually chaos for flows is described in terms of a return map.

PROOF OF PROPOSITION 4.5. As shown, for example, in [19], there is a compact invariant subset $S \subset V_0 \cup V_1$ on which the Poincaré map F is chaotic in the sense of Devaney (see [8]), that is

(i) the periodic points are dense;
(ii) there is a dense orbit;
(iii) there exists $\delta > 0$ such that if $x \in S$ there is $y \in S$ arbitrarily close to x such that $|F^k(x) - F^k(y)| > \delta$ for some $k \geqslant 0$.

Then we define

$$\mathcal{S} = \{\phi^t(x) \colon x \in S, -\infty < t < \infty\}.$$

Clearly this set is invariant for system (36). To prove the compactness, first note that if $x \in S$, then there exist times $t_k(x)$ such that $\phi^{t_k}(x) = F^k(x)$ for all integers k. Now, using the notation of Section 4.1, $t_{k+1}(x) - t_k(x) = \tau_0(F^k(x))$ if $F^k(x) \in V_0$ or $\tau_1(F^k(x))$ if $F^k(x) \in V_1$ and so

$$c_1 \leqslant t_{k+1}(x) - t_k(x) \leqslant c_2,$$

where by properties of τ_0 and τ_1

$$c_1 = \frac{1}{2}\min\{T, T_1\}, \qquad c_2 = \frac{3}{2}\max\{T, T_1\}.$$

Now let $\phi^{s_m}(x_m)$ be a sequence in $\mathcal{S}$. Then there exists k_m such that $t_{k_m}(x_m) \leqslant s_m < t_{k_m+1}(x_m)$ and so it follows that $\phi^{s_m}(x_m) = \phi^{\sigma_m}(z_m)$, where $0 \leqslant \sigma_m = s_m - t_{k_m}(x_m) \leqslant c_2$ and $z_m = F^{k_m}(x_m) \in S$. Then there are subsequences $\sigma_{j_m} \to \sigma$ and $z_{j_m} \to z \in S$. By continuity of $\phi^t(x)$, it follows that $\phi^{s_{j_m}}(x_{j_m}) \to \phi^\sigma(z) \in \mathcal{S}$. Thus $\mathcal{S}$ is compact.

To prove (a) and (b), let $x = \phi^t(y)$ be in $\mathcal{S}$, where $y \in S$. Then there exists $t_k = t_k(y)$ such that $\phi^{t_k}(y) = F^k(y)$ and $t_k \leqslant t < t_{k+1}$. So $x = \phi^{t-t_k}(F^k(y))$. Given $\varepsilon > 0$, choose $\delta > 0$ so that $|z - F^k(y)| < \delta$ implies $|\phi^t(z) - \phi^t(F^k(y))| < \varepsilon$ for $0 \leqslant t \leqslant c_2$. Then we see that $|x - \phi^{t-t_k}(z)| < \varepsilon$. Since we can choose $z \in S$ to be periodic for F so that $\phi^{t-t_k}(z)$ is periodic for the flow, it follows that the periodic points are dense in $\mathcal{S}$. Since we can choose $z \in S$ to be on the orbit of F which is dense in S, it follows that the orbit of z in the flow is dense in $\mathcal{S}$.

To prove (c), suppose $x \in S$. Then we know there exists $y \in S$ arbitrarily close to x such that $|F^k(y) - F^k(x)| > \delta$ for some $k \geqslant 0$. In the following δ_1 will be a positive number which will be determined as we proceed. Also we write

$$\Delta = \inf_{x \in \mathcal{S}} |f(x)| > 0.$$

Let $\alpha(t)$ be a continuous nonnegative function with $\alpha(0) = 0$. Suppose

$$|\phi^{\alpha(t)}(y) - \phi^t(x)| \leqslant \delta_1$$

for all $t \geqslant 0$. Now we apply Lemma 3.1 with $\phi^{\alpha(t)}(y)$ as z, $\phi^t(x)$ as x, $v = f(\phi^t(x))/|f(\phi^t(x))|$ and $T = 0$ to deduce that if

$$\delta_1 < \min\left\{\frac{\Delta}{4M_1}, \frac{\Delta^2}{8M_0M_1}\right\},$$

there exists $\tau = \tau(t)$ with $|\tau| \leqslant 2\delta_1/\Delta$ such that

$$\langle \phi^{\alpha(t)+\tau}(y) - \phi^t(x), f(\phi^t(x)) \rangle = 0.$$

Then if we define

$$\beta(t) = \alpha(t) + \tau(t),$$

we see that

$$\big\langle \phi^{\beta(t)}(y) - \phi^t(x), f\big(\phi^t(x)\big)\big\rangle = 0$$

and

$$\begin{aligned} \big|\phi^{\beta(t)}(y) - \phi^t(x)\big| &\leqslant \big|\phi^{\beta(t)}(y) - \phi^{\alpha(t)}(y)\big| + \big|\phi^{\alpha(t)}(y) - \phi^t(x)\big| \\ &\leqslant M_0\big|\tau(t)\big| + \delta_1 \leqslant \delta_2, \end{aligned} \tag{38}$$

where

$$\delta_2 = (2M_0/\Delta + 1)\delta_1.$$

Note it also follows from Remark 3.2 that $\tau(t)$ and hence $\beta(t)$ is continuous. Now we show that $\beta(t)$ is, in fact, differentiable provided that

$$M_1\delta_2 < \Delta.$$

To this end, consider the continuously differentiable real function

$$g(\beta, t) = \big\langle \phi^{\beta}(y) - \phi^t(x), f\big(\phi^t(x)\big)\big\rangle. \tag{39}$$

We estimate

$$\begin{aligned} g_\beta\big(\beta(t), t\big) &= \big\langle f\big(\phi^{\beta(t)}(y)\big), f\big(\phi^t(x)\big)\big\rangle \\ &\geqslant \big|f\big(\phi^t(x)\big)\big|^2 - \big|f\big(\phi^{\beta(t)}(y)\big) - f\big(\phi^t(x)\big)\big|\big|f\big(\phi^t(x)\big)\big| \\ &\geqslant \big|f\big(\phi^t(x)\big)\big|[\Delta - M_1\delta_2] \\ &> 0. \end{aligned}$$

Then it follows from the continuity of $\beta(t)$ and the implicit function theorem that $\beta(t)$ is continuously differentiable. Moreover, if we differentiate the equation $g(\beta(t), t) = 0$ with respect to t, we obtain the equation

$$\begin{aligned} &\big\langle f\big(\phi^{\beta(t)}(y)\big), f\big(\phi^t(x)\big)\big\rangle\beta'(t) \\ &\quad - \big|f\big(\phi^t(x)\big)\big|^2 + \big\langle \phi^{\beta(t)}(y) - \phi^t(x), f'\big(\phi^t(x)\big) f\big(\phi^t(x)\big)\big\rangle = 0 \end{aligned}$$

so that $\beta'(t)$ is given by

$$\begin{aligned} &1 - \big[\big\langle \phi^{\beta(t)}(y) - \phi^t(x), f'\big(\phi^t(x)\big) f\big(\phi^t(x)\big)\big\rangle \\ &\quad + \big\langle f\big(\phi^{\beta(t)}(y)\big) - f\big(\phi^t(x)\big), f\big(\phi^t(x)\big)\big\rangle\big] \big/ \big\langle f\big(\phi^{\beta(t)}(y)\big), f\big(\phi^t(x)\big)\big\rangle \end{aligned}$$

from which we see, using the estimate after (39), that

$$\left|\beta'(t) - 1\right| \leqslant 2(\Delta - M_1\delta_2)^{-1}M_1\delta_2. \tag{40}$$

Now there is a sequence $t_k = t_k(x)$ such that $\phi^{t_k}(x) = F^k(x)$ for $k \geqslant 0$. We apply Lemma 3.1 with $\phi^{\beta(t_k)}(y)$ as z, $\phi^{t_k}(x)$ as x, $T = 0$ and $v = f(u_0(0))/|f(u_0(0))|$. Note that by (38), $|\phi^{\beta(t_k)}(y) - \phi^{t_k}(x)| \leqslant \delta_2$ and that since $\phi^{t_k}(x) \in N$,

$$\left|\left\langle f\left(\phi^{t_k}(x)\right), f\left(u_0(0)\right)\right\rangle\right| \geqslant \frac{1}{2}\left|f\left(u_0(0)\right)\right|^2$$

so that

$$\left|\left\langle f\left(\phi^{t_k}(x)\right), v\right\rangle\right| \geqslant \frac{1}{2}\Delta.$$

Then if

$$8M_1\delta_2 < \Delta, \qquad 32M_0M_1\delta_2 < \Delta^2,$$

it follows from Lemma 3.1 that there exists a h_k satisfying $|h_k| \leqslant 4\Delta^{-1}\delta_2$ which is unique in $|h_k| \leqslant \Delta/(8M_0M_1)$ such that

$$\left\langle \phi^{\beta(t_k)+h_k}(y) - \phi^{t_k}(x), f\left(u_0(0)\right)\right\rangle = 0.$$

Now we show that for $k \geqslant 0$, $\phi^{\beta(t_k)+h_k}(y) \in S$ and

$$\phi^{\beta(t_k)+h_k}(y) = F^k(y). \tag{41}$$

Note when $k = 0$ that the equation

$$\left\langle \phi^{\beta(t_0)+h}(y) - \phi^{t_0}(x), f\left(u_0(0)\right)\right\rangle = 0$$

has the solution $h = -\beta(0)$ since $t_0 = 0$ and $x, y \in S$ which is in the hyperplane orthogonal to $f(u_0(0)$. Since

$$\left|\beta(0)\right| = \left|\tau(0)\right| \leqslant 2\Delta^{-1}\delta_1 \leqslant 2\Delta^{-1}\delta_2 < \Delta/(8M_0M_1),$$

it follows from uniqueness that $h_0 = -\beta(t_0)$ so that $\beta(t_0) + h_0 = 0$. Hence (41) holds for $k = 0$ and, of course, $y \in S$.

Now we use induction to complete the proof. We suppose for some $k \geqslant 0$ that $\phi^{\beta(t_k)+h_k}(y) \in S$ and (41) holds. Note, using (40), that

$$\begin{aligned}&\left|\beta(t_{k+1}) + h_{k+1} - \left(\beta(t_k) + h_k\right) - (t_{k+1} - t_k)\right| \\ &\quad \leqslant \left|\beta(t_{k+1}) - \beta(t_k) - (t_{k+1} - t_k)\right| + |h_{k+1}| + |h_k|\end{aligned}$$

$$
\begin{aligned}
&\leqslant 2(\Delta - M_1\delta_2)^{-1}M_1\delta_2(t_{k+1}-t_k) + 8\Delta^{-1}\delta_2\\
&\leqslant 2(\Delta - M_1\delta_2)^{-1}M_1c_2\delta_2 + 8\Delta^{-1}\delta_2\\
&\leqslant \Delta/(16M_0M_1) + \Delta/(16M_0M_1)\\
&= \Delta/(8M_0M_1),
\end{aligned}
$$

provided that

$$64M_0M_1^2c_2\delta_2 < \Delta^2, \qquad 128M_0M_1\delta_2 < \Delta^2.$$

Note also that

$$\left|\phi^{\beta(t_k)+h_k}(y) - \phi^{t_k}(x)\right| \leqslant M_0|h_k| + \left|\phi^{\beta(t_k)}(y) - \phi^{t_k}(x)\right| \leqslant (4M_0\Delta^{-1}+1)\delta_2.$$

Next we assume δ_1 is so small that

$$(4M_0\Delta^{-1}+1)\delta_2 \leqslant \frac{\mathrm{e}^{-M_1c_2}|f(u_0(0))|}{8M_1}\min\left\{1, \frac{|f(u_0(0))|}{4M_0}\right\}$$

and such that

$$\left|\tau(x) - \tau(y)\right| \leqslant \Delta/(8M_0M_1)$$

if x, y are in S and $|x-y| \leqslant (4M_0\Delta^{-1}+1)\delta_2$, where $\tau(x)$ is the function such that $F(x) = \phi^{\tau(x)}(x)$ for $x \in V_0 \cup V_1$. From the latter we conclude that

$$\left|\tau\left(\phi^{\beta(t_k)+h_k}(y)\right) - (t_{k+1}-t_k)\right| = \left|\tau\left(\phi^{\beta(t_k)+h_k}(y)\right) - \tau\left(\phi^{t_k}(x)\right)\right| \leqslant \Delta/(8M_0M_1).$$

Then it follows by the uniqueness in Lemma 3.1 with $\phi^{t_k}(x)$ as x, $z = \phi^{\beta(t_k)+h_k}(y)$, $T = t_{k+1} - t_k = \tau(\phi^{t_k}(x))$, $v = f(u_0(0))/|f(u_0(0))|$ and

$$\alpha = \frac{\langle f(\phi^{t_{k+1}}(x)), f(u_0(0))\rangle}{4M_0M_1|f(u_0(0))|} \quad \left(\geqslant \Delta/(8M_0M_1)\right)$$

that

$$\beta(t_{k+1}) + h_{k+1} - \left(\beta(t_k) + h_k\right) = \tau\left(\phi^{\beta(t_k)+h_k}(y)\right).$$

Hence

$$\phi^{\beta(t_{k+1})+h_{k+1}}(y) = F\left(F^k(y)\right) = F^{k+1}(y) \in S.$$

This finishes the induction proof and so we know that $\phi^{\beta(t_k)+h_k}(y) \in S$ and (41) holds for all $k \geqslant 0$.

Hence we conclude that for $k \geqslant 0$

$$\left|F^k(y) - F^k(x)\right| = \left|\phi^{\beta(t_k)+h_k}(y) - \phi^{t_k}(x)\right| \leqslant (4M_0/\Delta + 1)\delta_2.$$

This is a contradiction if

$$(4M_0/\Delta + 1)\delta_2 \leqslant \delta.$$

So we conclude that if $x \in S$ and for some $y \in S$ there exists $k \geqslant 0$ such that $|F^k(y) - F^k(x)| > \delta$, then if $\alpha(t)$ is a continuous nonnegative function with $\alpha(0) = 0$ we must have

$$\left|\phi^{\alpha(t)}(y) - \phi^t(x)\right| > \delta_1$$

for some $t \geqslant 0$, where δ_1 is a positive number satisfying all the conditions given above.

Now suppose $x \in \mathcal{S}$. Then, as at the beginning of this proof, $x = \phi^s(z)$ where $z \in S$ and $0 \leqslant s \leqslant c_2$. Let the nonnegative continuous function $\alpha(t)$ with $\alpha(0) = 0$ be given. We define the continuous function

$$\tilde{\alpha}(t) = \begin{cases} t & \text{if } 0 \leqslant t \leqslant s, \\ \alpha(t-s) + s, & \text{if } t \geqslant s. \end{cases}$$

Now, applying the first part of this proof to $\tilde{\alpha}(t)$ instead of $\alpha(t)$, we deduce that there exists $w \in S$ arbitrarily close to z such that

$$\left|\phi^{\tilde{\alpha}(t)}(w) - \phi^t(z)\right| > \delta_1$$

for some $t \geqslant 0$. Note that if w is sufficiently close to z then we can assume $t \geqslant s$. So we have

$$\left|\phi^{\alpha(t-s)+s}(w) - \phi^{t-s}(x)\right| > \delta_1$$

for some $t \geqslant s$. Hence

$$\left|\phi^{\alpha(t)}\big(\phi^s(w)\big) - \phi^t(x)\right| > \delta_1$$

for some $t \geqslant 0$, where $\phi^s(w)$ is in $\mathcal{S}$ and can be taken arbitrarily close to x. This completes the proof of (c) and hence of the proposition. ☐

5. Robustness of transversal periodic-to-periodic homoclinic orbits

In this section we consider a system depending on a parameter

$$\dot{x} = f(x, \mu) \tag{42}$$

where we assume the unperturbed system

$$\dot{x} = f(x, 0) \tag{43}$$

has a hyperbolic T-periodic orbit $u_0(t)$ with associated transversal homoclinic orbit $p_0(t)$. Our aim is to show that the perturbed system has a similar structure.

THEOREM 5.1. *Let* $f(x, \mu)$ *be a* C^3 *function. Suppose system* (43) *has a hyperbolic* T*-periodic orbit* $u_0(t)$ *and a transversal homoclinic orbit* $p_0(t)$ *to* $u_0(t)$. *Then*

(i) *for* μ *sufficiently small, the perturbed system* (42) *has a hyperbolic periodic orbit* $u(t, \mu)$ *with* $u(t, 0) = u_0(t)$;

(ii) *for* μ *sufficiently small,* (42) *has a transversal homoclinic orbit* $x(t, \mu)$ *associated with the hyperbolic periodic orbit* $u(t, \mu)$ *with* $x(t, 0) = p_0(t)$.

PROOF. (i) follows from standard theorems [10].

As in Proposition 3.5, the variational system

$$\dot{x} = f_x\bigl(u_0(t), 0\bigr)x$$

has a trichotomy on $(-\infty, \infty)$ with projections P_0, P_+, P_- and constants $K \geqslant 1$ and $\alpha > 0$.

Denote by γ^+ $(0 \leqslant \gamma^+ < T)$ the forward asymptotic phase for $p_0(t)$ and by γ^- $(0 \leqslant \gamma^- < T)$ the backward asymptotic phase. Note there exists a positive integer m such that

$$\bigl|p_0(t) - u_0(t + \gamma^+)\bigr| < \min\{\Delta, \xi_0/K\}$$

if $t \geqslant mT - \gamma^+$, where Δ and ξ_0 are as in Proposition 3.5. It follows by uniqueness that

$$p_0(t + mT - \gamma^+) = x^+(t, \xi_0, 0),$$

where $\xi_0 = P_+[p_0(mT - \gamma^+) - u_0(0)]$. Then

$$p_0(0) = x^+(-mT + \gamma^+, \xi_0, 0).$$

Similarly,

$$p_0(0) = x^-(mT + \gamma^-, \eta_0, 0)$$

where $\eta_0 = P_-[p_0(-mT - \gamma^-) - u_0(0)]$, provided that m also satisfies

$$\bigl|p_0(t) - u_0(t + \gamma^-)\bigr| < \min\{\Delta, \eta_0/K\}$$

if $t \leqslant -mT - \gamma^-$, where η_0 is as in Proposition 3.9.

Now it follows from Proposition 4.4 that the variational system

$$\dot{x} = f_x\bigl(p_0(t), 0\bigr)x \tag{44}$$

has a trichotomy on $\mathbf{R}$ with (say) projections Q_0, Q_+, Q_- where the range of Q_0 is spanned by $f(p_0(0), 0)$.

To find homoclinic orbits of (42) near $p_0(t)$, we solve the equation

$$F(\gamma, \xi, \eta, \mu) = x^+(-mT + \gamma, \xi, \mu) - x^-(mT + \gamma^-, \eta, \mu) = 0 \tag{45}$$

for $(\gamma, \xi, \eta) \in \mathbf{R} \times \mathcal{R}(P_+) \times \mathcal{R}(P_-)$ near $(\gamma^+, \xi_0, \eta_0)$, where we note that as a consequence of Proposition 3.5, F is a C^1 function. Note that

$$F(\gamma^+, \xi_0, \eta_0, 0) = p_0(0) - p_0(0) = 0.$$

We use the implicit function theorem. Write $z_0 = (\gamma^+, \xi_0, \eta_0)$. Then

$$F(z_0, 0) = 0.$$

Now we show $F_z(z_0, 0)$ is invertible. Note that if $z = (\gamma, \xi, \eta)$

$$\begin{aligned} F_z(z_0, 0)z &= \gamma x_t^+(-mT + \gamma^+, \xi_0, 0) + x_\xi^+(-mT + \gamma^+, \xi_0, 0)\xi \\ &\quad - x_\eta^-(mT + \gamma^-, \eta_0, 0)\eta \\ &= \gamma f\big(p_0(0), 0\big) + x_\xi^+(-mT + \gamma^+, \xi_0, 0)\xi - x_\eta^-(mT + \gamma^-, \eta_0, 0)\eta. \end{aligned}$$

Now it follows from Proposition 3.5 that $Z(t) = x_\xi^+(t - mT + \gamma^+, \xi_0, 0)$ is a solution of (44) restricted to $\mathcal{R}(P_+)$ such that $\|Z\|_\gamma < \infty$ and $P_+Z(mT - \gamma^+) = P_+$. It follows that the range of $x_\xi^+(-mT + \gamma^+, \xi_0, 0)$ is contained in the range of Q_+. However the condition $P_+X(mT - \gamma^+) = P_+$ implies that rank $x_\xi^+(-mT + \gamma^+, \xi_0, 0) =$ rank $P_+ =$ rank Q_+ so that the range of $x_\xi^+(-mT + \gamma^+, \xi_0, 0)$ coincides with the range of Q_+. Similarly, the range of $x_\eta^-(mT + \gamma^-, \eta_0, 0)$ coincides with the range of Q_-. Hence

$$\mathcal{R}\big(F_z(z_0, 0)\big) = \operatorname{span}\big\{f\big(p_0(0), 0\big)\big\} \oplus \mathcal{R}(Q_+) \oplus \mathcal{R}(Q_-) = \mathbf{R}^n$$

and so $F_z(z_0, 0)$ is invertible.

Then we deduce from the implicit function theorem that Eq. (45) has a C^1 solution $(\gamma(\mu), \xi(\mu), \eta(\mu))$ such that $(\gamma(0), \xi(0), \eta(0)) = (\gamma^+, \xi_0, \eta_0)$. Then

$$x(t, \mu) = \begin{cases} x^+(t - mT + \gamma(\mu), \xi(\mu), \mu) & \text{for } t \geqslant 0, \\ x^-(t + mT + \gamma^-, \eta(\mu), \mu) & \text{for } t \leqslant 0 \end{cases}$$

is a solution of (42) such that

$$\big|x(t, \mu) - u\big(t + \gamma(\mu), \mu\big)\big| \leqslant \Delta \mathrm{e}^{-\gamma(t - mT + \gamma(\mu))} \quad \text{for } t \geqslant mT - \gamma(\mu)$$

and

$$\big|x(t, \mu) - u(t + \gamma^-, \mu)\big| \leqslant \Delta \mathrm{e}^{\gamma(t + mT + \gamma^-)} \quad \text{for } t \leqslant -mT - \gamma^-.$$

So $x(t, \mu)$ is a homoclinic orbit associated with the hyperbolic periodic orbit $u_\mu(t) = u(t, \mu)$. Note also that

$$x(t, 0) = p_0(t).$$

To verify that the homoclinic orbit is transversal, note it follows from the proofs of Propositions 3.12 and 3.13 that for

$$x(0, \mu) = x^+\big(-mT + \gamma(\mu), \xi(\mu), \mu\big) = x^-\big(mT + \gamma^-, \eta(\mu), \mu\big),$$

the tangent space $T_{x(0,\mu)}W^s(u_\mu)$ is spanned by $f(x(0, \mu), \mu)$ and the range of $x^+_\xi(-mT + \gamma(\mu), \xi(\mu), \mu)$, and the tangent space $T_{x(0,\mu)}W^u(u_\mu)$ is spanned by $f(x(0, \mu), \mu)$ and the range of $x^-_\eta(mT + \gamma^-, \eta(\mu), \mu)$. Then

$$w \in T_{x(0,\mu)}W^s(u_\mu) \cap T_{x(0,\mu)}W^u(u_\mu)$$

if and only if there exist $\gamma_1 \in \mathbf{R}$, $\xi \in \mathcal{R}(P_+)$, $\gamma_2 \in \mathbf{R}$ and $\eta \in \mathcal{R}(P_-)$ such that

$$\begin{aligned} w &= \gamma_1 f\big(x(0, \mu), \mu\big) + x^+_\xi\big(-mT + \gamma(\mu), \xi(\mu), \mu\big)\xi \\ &= \gamma_2 f\big(x(0, \mu), \mu\big) + x^-_\eta\big(mT + \gamma^-, \eta(\mu), \mu\big)\eta. \end{aligned}$$

Now note that

$$\begin{aligned} &F_z\big(\gamma(\mu), \xi(\mu), \eta(\mu), \mu\big)(\gamma_1 - \gamma_2, \xi, \eta) \\ &\quad = (\gamma_1 - \gamma_2) f\big(x(0, \mu), \mu\big) + x^+_\xi\big(-mT + \gamma(\mu), \xi(\mu), \mu\big)\xi \\ &\qquad - x^-_\eta\big(mT + \gamma^-, \eta(\mu), \mu\big)\eta \\ &\quad = w - w \\ &\quad = 0. \end{aligned}$$

However, when $\mu = 0$, this derivative is $F_z(z_0, 0)$, which is invertible, and hence still invertible for μ sufficiently small. So $(\gamma_1 - \gamma_2, \xi, \eta) = 0$ and $w = \gamma_1 f(x(0, \mu), \mu)$. Thus, for μ sufficiently small,

$$T_{x(0,\mu)}W^s(u_\mu) \cap T_{x(0,\mu)}W^u(u_\mu) = \operatorname{span}\big\{f\big(x(0, \mu), \mu\big)\big\}$$

and so $x(t, \mu)$ is a transversal homoclinic orbit. Thus we have proved the theorem. □

6. Finding transversal periodic-to-periodic homoclinic orbits through regular perturbation

Even though, as we found in the previous section, transversal periodic-to-periodic homoclinic orbits persist under perturbation, it does not seem possible to write down an explicit system with an explicit transversal periodic-to-periodic homoclinic orbit. However, it turns out to be quite easy to write down an explicit system with an explicit nontransversal homoclinic orbit and obtain a transversal orbit by perturbation. To this end, as in the previous section, we consider a system depending on a parameter

$$\dot{x} = f(x, \mu). \tag{46}$$

We assume the unperturbed system

$$\dot{x} = f(x, 0) \tag{47}$$

has a hyperbolic T-periodic orbit $u_0(t)$ with associated homoclinic orbit $p_0(t)$. As in Proposition 3.5, this means that the variational system

$$\dot{x} = f_x\big(u_0(t), 0\big)x$$

has a trichotomy with projections P_0, P_+, P_- and constants K, α. Note, again as in Proposition 3.5, it follows by standard theorems that the perturbed system (46) has a periodic orbit $u(t, \mu)$ with $u(t, 0) = u_0(t)$.

Denote by γ^+ $(0 \leqslant \gamma^+ < T)$ the forward asymptotic phase for $p_0(t)$ and by γ^- $(0 \leqslant \gamma^- < T)$ the backward asymptotic phase. Then

$$p_0(0) \in W^{s,\gamma^+}(u_0) \cap W^{u,\gamma^-}(u_0).$$

What we suppose here is that $W^{s,\gamma^+}(u_0)$ and $W^{u,\gamma^-}(u_0)$ intersect in a curve C containing $p_0(0)$ which certainly implies that $p_0(t)$ cannot be transversal. So we are supposing there is a function $p(t, \beta)$ defined for all real t and β near 0 with $p(t, 0) = p_0(t)$ such that for each β, $p(t, \beta)$ is homoclinic to $u_0(t)$ with asymptotic phases γ^+ and γ^-.

THEOREM 6.1. *Let $f(x, \mu)$ be a C^4 function. Suppose system* (47) *has a hyperbolic T-periodic orbit $u_0(t)$ with associated homoclinic orbit $p_0(t)$ with asymptotic phases γ^+ and γ^- such that the variational system*

$$\dot{x} = f_x\big(p_0(t), 0\big)x \tag{48}$$

has a two-dimensional subspace of bounded solutions. Suppose $W^{s,\gamma^+}(u_0)$ and $W^{u,\gamma^-}(u_0)$ intersect in a C^1 curve $p(\beta)$ with $p(0) = p_0(0)$ and denote by $p(t, \beta)$ the solution of (47) *with $p(0, \beta) = p(\beta)$. Then*

(i) *for μ sufficiently small, the perturbed system* (46) *has a hyperbolic periodic orbit $u_\mu(t) = u(t, \mu)$ with $u(t, 0) = u_0(t)$;*

(ii) *the adjoint system*

$$\dot{x} = -f_x\big(p(t, \beta), 0\big)^* x \tag{49}$$

has, up to a scalar multiple, a unique nontrivial solution $\psi(t,\beta)$ *with* $\psi(t,\beta)\to 0$ *as* $|t|\to\infty$ *and if the Melnikov function*

$$\int_{-\infty}^{\infty}\psi^*(t,\beta)f_\mu\bigl(p(t,\beta),0\bigr)\,\mathrm{d}t$$

has a simple zero at $\beta=0$, *then for* $\mu\neq 0$ *sufficiently small, the perturbed system* (46) *has a transversal homoclinic orbit* $y(t,\mu)$ *associated with the hyperbolic periodic orbit* $u(t,\mu)$ *with* $y(t,0)=p_0(t)$.

PROOF. (i) follows from standard theorems as in Proposition 3.5.

Now, as in Proposition 3.5, the variational system

$$\dot{x}=f_x\bigl(u_0(t),0\bigr)x$$

has a trichotomy on **R** with projections P_0, P_+, P_- and constants $K\geqslant 1$ and $\alpha>0$.

As in the proof of Theorem 5.1, there exists a positive integer m such that

$$p_0(0)=x^+(-mT+\gamma^+,\xi_0,0),\quad \text{where } \xi_0=P_+\bigl[p_0(mT-\gamma^+)-u_0(0)\bigr].$$

So, in a neighbourhood of $p_0(0)$, $W^{s,\gamma^+}(u_\mu)$ can be parametrized as $x^+(-mT+\gamma^+,\xi,\mu)$, where $\xi\in\mathcal{R}(P_+)$ is near ξ_0. Similarly, in the neighbourhood of $p_0(0)$, $W^{u,\gamma^-}(u_\mu)$ can be parametrized as $x^-(mT+\gamma^-,\eta,\mu)$, where η is near

$$\eta_0=P_-\bigl[p_0(-mT-\gamma^-)-u_0(0)\bigr].$$

So we can write

$$p(\beta)=x^+\bigl(-mT+\gamma^+,\xi(\beta),0\bigr)=x^-\bigl(mT+\gamma^-,\eta(\beta),0\bigr),$$

where $\xi(\beta)$ and $\eta(\beta)$ are C^1 functions with $\xi(0)=\xi_0$ and $\eta(0)=\eta_0$.

Note that since

$$p_\beta(t,\beta)=x_\xi^+\bigl(t-mT+\gamma^+,\xi(\beta),0\bigr)\xi'(\beta)=x_\eta^-\bigl(t+mT+\gamma^-,\eta(\beta),0\bigr)\eta'(\beta),$$

it follows from Propositions 3.5 and 3.9 that $p_\beta(t,\beta)\to 0$ as $|t|\to\infty$. Next, by Proposition 3.5 again,

$$\begin{aligned}\bigl|p(t,\beta)-u_0(t+\gamma^+)\bigr|&=\bigl|x^+\bigl(t-mT+\gamma^+,\xi(\beta),0\bigr)-u_0(t-mT+\gamma^+)\bigr|\\&\leqslant\Delta\mathrm{e}^{-\gamma(t-mT+\gamma^+)}\end{aligned}\tag{50}$$

if $t\geqslant mT-\gamma^+$ and using Proposition 3.9 we get a similar inequality for $|p(t,\beta)-u_0(t+\gamma^-)|$ in $t\leqslant -mT-\gamma^-$. This implies that the norm of $p_t(t,\beta)=f(p(t,\beta))$ has a uniform upper bound and positive lower bound independent of β. In particular, this means that $p_t(t,\beta)$ and $p_\beta(t,\beta)$ are independent bounded solutions of the variational system

$$\dot{x} = f_x\bigl(p(t,\beta),0\bigr)x. \tag{51}$$

Next the last inequality above implies that for $t \geqslant t_1$,

$$\bigl|f_x\bigl(p(t,\beta),0\bigr) - f_x\bigl(u_0(t+\gamma^+),0\bigr)\bigr| \leqslant \delta(t_1),$$

where $\delta(t_1) \to 0$ as $t_1 \to \infty$ uniformly with respect to β. It follows from the roughness result in Remark 2.7 that if t_1 is large enough, not depending on β, system (51) has a trichotomy on $[t_1,\infty)$ with projections $P_0(\beta)$, $P_+(\beta)$, $P_-(\beta)$ such that $\mathcal{R}(P_0(\beta)) = \operatorname{span}\{p_t(0,\beta)\}$ and with exponent and constant independent of β. Next by Remark 2.3, Eq. (51) has a trichotomy on $[0,\infty)$ with the same projections and exponent but a different constant perhaps.

Similarly, (51) has a trichotomy on $\mathbf{R}_-$ with projections $Q_0(\beta)$, $Q_+(\beta)$, $Q_-(\beta)$. Note that the range of $P_0(\beta)$ and $Q_0(\beta)$ coincide as the span of $p_t(0,\beta)$. Also from Remark 2.8, we know that the projections $P_\sigma(\beta)$ and $Q_\sigma(\beta)$ are C^1 in β. Now the subspace of initial values of bounded solutions of (51) is

$$\mathcal{R}\bigl(P_0(\beta)+P_+(\beta)\bigr) \cap \mathcal{R}\bigl(Q_0(\beta)+Q_-(\beta)\bigr).$$

By hypothesis, when $\beta = 0$ this subspace has dimension 2. Since the projections are continuous, for small β the dimension is at most 2. However, $p_t(0,\beta)$ and $p_\beta(t,\beta)$ are linearly independent bounded solutions. So the dimension is exactly 2.

Next the adjoint equation (49) has a trichotomy on $\mathbf{R}_+$ with projections $P_0^*(\beta)$, $P_-^*(\beta)$, $P_+^*(\beta)$ and on $\mathbf{R}_-$ with projections $Q_0^*(\beta)$, $Q_-^*(\beta)$, $Q_+^*(\beta)$. The subspace of initial values at $t = 0$ of solutions $x(t)$ with $|x(t)| \to 0$ as $|t| \to \infty$ is

$$\mathcal{R}\bigl(P_-^*(\beta)\bigr) \cap \mathcal{R}\bigl(Q_+^*(\beta)\bigr) = V(\beta)^\perp,$$

where

$$V(\beta) = \mathcal{R}\bigl(P_0(\beta)+P_+(\beta)\bigr) + \mathcal{R}\bigl(Q_0(\beta)+Q_-(\beta)\bigr).$$

$V(\beta)^\perp$ is one-dimensional since the subspaces $\mathcal{R}(P_0(\beta)+P_+(\beta))$ and $\mathcal{R}(Q_0(\beta)+Q_-(\beta))$ have a two-dimensional intersection and their dimensions sum to $n+1$.

To get a C^1 basis for $V(\beta)$, we begin with bases for $\mathcal{R}(P_0(0)+P_+(0))$ and $\mathcal{R}(Q_0(0)+Q_-(0))$ containing $p_t(0,0)$ and $p_\beta(t,0)$. Then we obtain a C^1 basis for $V(\beta)$ by taking $p_t(0,\beta)$ and $p_\beta(t,\beta)$ and by applying the projections $P_0(\beta)+P_+(\beta)$ and $Q_0(\beta)+Q_+(\beta)$ to the other vectors. We assemble these vectors into an $n \times (n-1)$ matrix. Then the vector whose ith component is $(-i)^i$ times the determinant of the matrix obtained by deleting the ith row is nonzero, depends C^1 on β and is orthogonal to all the vectors in the basis. Dividing by its norm, we obtain a C^1 unit vector $\psi(\beta)$ which spans $V(\beta)^\perp$. Denote by

$\psi(t,\beta)$ the solution of the adjoint equation (49) with $\psi(0,\beta)=\psi(\beta)$. Up to a scalar multiple, it is the unique solution of (49) which tends to zero as $|t|\to\infty$.

To find homoclinic orbits near $p_0(t)$, we solve the equation

$$F(\gamma,\xi,\eta,\mu)=x^+(-mT+\gamma,\xi,\mu)-x^-(mT+\gamma^-,\eta,\mu)=0$$

for (γ,ξ,η) near (γ^+,ξ_0,η_0). Note that by Propositions 3.5 and 3.9, F is a C^2 function. Also we have

$$F\big(\gamma^+,\xi(\beta),\eta(\beta),0\big)=p(0,\beta)-p(0,\beta)=0.$$

We use the Crandall–Rabinowitz theorem [6] as given in Theorem 4.1 in [17], a suitable version of which can be stated as follows:

Let $F:E\times\mathbf{R}\mapsto G$, $(z,\mu)\mapsto F(z,\mu)$, *be a* C^2 *mapping, where* E *and* G *are Banach spaces. Suppose that there exists a* C^2 *function* $\phi(\beta)$ *defined on an interval* I *such that* $\phi'(\beta)\neq 0$ *and such that*

$$F\big(\phi(\beta),0\big)=0$$

and $L(\beta)=F_z(\phi(\beta),0)$ *is Fredholm of index zero with nullspace spanned by* $\phi'(\beta)$. *Define*

$$d(\beta)=\psi(\beta)\big(F_\mu\big(\phi(\beta),0\big)\big),$$

where $\psi(\beta)\in G^*$ *is a* C^1 *function such that* $\mathcal{N}(\psi(\beta))=\mathcal{R}(L(\beta))$. *Then if* $d(\beta)$ *has a simple zero at* β_0, *the equation*

$$F(z,\mu)=0$$

has a solution $z(\mu)$ *for* μ *sufficiently small. Moreover,* $z(0)=\phi(\beta_0)$, $z(\mu)$ *is a* C^1 *function and* $F_z(z(\mu),\mu)$ *is invertible if* $\mu\neq 0$.

We apply this theorem with $E=\mathbf{R}\times\mathcal{R}(P_+)\times\mathcal{R}(P_-)$ and $G=\mathbf{R}^n$. Write $z=(\gamma,\xi,\eta)$ and $\phi(\beta)=(\gamma^+,\xi(\beta),\eta(\beta))$. Then

$$F\big(\phi(\beta),0\big)=0.$$

Now we examine $F_z(\phi(\beta),0)$. Note if $z=(\gamma,\xi,\eta)$ that

$$\begin{aligned}F_z\big(\phi(\beta),0\big)z&=\gamma x_t^+\big(-mT+\gamma^+,\xi(\beta),0\big)+x_\xi^+\big(-mT+\gamma^+,\xi(\beta),0\big)\xi\\&\quad-x_\eta^-\big(mT+\gamma^-,\eta(\beta),0\big)\eta\\&=\gamma f\big(p(0,\beta),0\big)+x_\xi^+\big(-mT+\gamma^+,\xi(\beta),0\big)\xi\\&\quad-x_\eta^-\big(mT+\gamma^-,\eta(\beta),0\big)\eta.\end{aligned}$$

Reasoning as in the proof of Theorem 5.1, we find that

$$\mathcal{R}\big(F_z\big(\phi(\beta),0\big)\big)=\operatorname{span}\big\{f\big(p(0,\beta),0\big)\big\}\oplus\big[\mathcal{R}\big(P_+(\beta)\big)+\mathcal{R}\big(Q_-(\beta)\big)\big]$$

so that

$$\mathcal{R}\big(F_z\big(\phi(\beta),0\big)\big)=\operatorname{span}\big\{\psi(\beta)\big\}^{\perp}.$$

(Note that $\psi(\beta)$ can be regarded as the linear functional $x\mapsto\psi(\beta)^*x$ and the last subspace is its nullspace.) From this it follows that $\dim\mathcal{N}(F_z(\phi(\beta),0))=1$ and so

$$\mathcal{N}\big(F_z\big(\phi(\beta),0\big)\big)=\operatorname{span}\big\{\phi'(\beta)\big\}.$$

Next we calculate the Melnikov function

$$d(\beta)=\psi(\beta)^*F_\mu\big(\phi(\beta),0\big).$$

Now

$$F_\mu\big(\phi(\beta),0\big)=z_\mu^+\big(-mT+\gamma^+,\xi(\beta),0\big)-z_\mu^-\big(mT+\gamma^-,\eta(\beta),0\big),$$

where $z^+(t,\xi,\mu)=x^+(t,\xi,\mu)-u(t,\mu)$ and $z^-(t,\eta,\mu)=x^-(t,\eta,\mu)-u(t,\mu)$. By differentiation with respect to μ at $\mu=0$ and using the fact that $x^+(t,\xi(\beta),0)=p(t+mT-\gamma^+,\beta)$, we find that $w(t)=z_\mu^+(t-mT+\gamma^+,\xi(\beta),0)$ is a solution of

$$\dot w=f_x\big(p(t,\beta),0\big)w+h(t),$$

where

$$\begin{aligned}h(t)&=f_x\big(p(t,\beta),0\big)u_\mu(t+\gamma^+,0)-u_{\mu t}(t+\gamma^+,0)+f_\mu\big(p(t,\beta),0\big)\\&=\big[f_x\big(p(t,\beta),0\big)-f_x\big(u_0(t+\gamma^+),0\big)\big]u_\mu(t+\gamma^+,0)\\&\quad+f_\mu\big(p(t,\beta),0\big)-f_\mu\big(u_0(t+\gamma^+),0\big)\end{aligned}$$

so that, by (50), $\|h\|_\gamma<\infty$. We also know from Proposition 3.5 that $\|w\|_\gamma<\infty$. So, by Lemma 3.6,

$$\begin{aligned}w(t)=Y(t,\beta)P_+(\beta)w(0)&+\int_0^t Y(t,\beta)P_+(\beta)Y^{-1}(s,\beta)h(s)\,\mathrm{d}s\\&-\int_t^\infty Y(t,\beta)\big(I-P_+(\beta)\big)Y^{-1}(s,\beta)h(s)\,\mathrm{d}s,\end{aligned}$$

where $Y(t,\beta)$ is the fundamental matrix of (51) with $Y(0,\beta)=I$. Thus

$$z_\mu^+\big(-mT+\gamma^+,\xi(\beta),0\big)=P_+(\beta)w(0)-\int_0^\infty\big(I-P_+(\beta)\big)Y^{-1}(t,\beta)h(t)\,\mathrm{d}t$$

and so since $\psi(\beta)^*P_+(\beta)=0$

$$\psi(\beta)^*z_\mu^+\big(-mT+\gamma^+,\xi(\beta),0\big)=-\int_0^\infty\psi(t,\beta)^*h(t)\,\mathrm{d}t.$$

Similarly,

$$\psi(\beta)^* z_\mu^-\big(mT+\gamma^+,\eta(\beta),0\big)=\int_{-\infty}^{0}\psi(t,\beta)^* h(t)\,\mathrm{d}t$$

and hence

$$d(\beta)=-\int_{-\infty}^{\infty}\psi(t,\beta)^* h(t)\,\mathrm{d}t.$$

However, integrating by parts,

$$\begin{aligned}\int_{-\infty}^{\infty}\psi(t,\beta)^* u_{\mu t}(t+\gamma^+,0)\,\mathrm{d}t &= -\int_{-\infty}^{\infty}\psi_t(t,\beta)^* u_\mu(t+\gamma^+,0)\,\mathrm{d}t\\ &= \int_{-\infty}^{\infty}\psi(t,\beta)^* f_x\big(p(t,\beta),0\big)u_\mu(t+\gamma^+,0)\,\mathrm{d}t\end{aligned}$$

and so

$$d(\beta)=-\int_{-\infty}^{\infty}\psi(t,\beta)^* f_\mu\big(p(t,\beta),0\big)\,\mathrm{d}t.$$

Since, by hypothesis, $d(\beta)$ has a simple zero at $\beta=0$ it follows from the Crandall–Rabinowitz theorem as stated above that the equation

$$F(\gamma,\xi,\eta,\mu)=0$$

has a solution $(\gamma(\mu),\xi(\mu),\eta(\mu))$ such that $(\gamma(0),\xi(0),\eta(0))=(\gamma^+,\xi_0,\eta_0)$. Then

$$x(t,\mu)=\begin{cases}x^+(t-mT+\gamma(\mu),\xi(\mu),\mu) & \text{for } t\geqslant 0,\\ x^-(t+mT+\gamma^-,\eta(\mu),\mu) & \text{for } t\leqslant 0\end{cases}$$

is a solution of (46) such that

$$\big|x(t,\mu)-u\big(t+\gamma(\mu),\mu\big)\big|\leqslant \Delta\mathrm{e}^{-\beta(t-mT+\gamma(\mu))}\quad \text{for } t\geqslant mT-\gamma(\mu)$$

and

$$\big|x(t,\mu)-u(t+\gamma^-,\mu)\big|\leqslant \Delta\mathrm{e}^{\beta(t+mT+\gamma^-)}\quad \text{for } t\leqslant -mT-\gamma^-.$$

So $x(t,\mu)$ is a homoclinic orbit associated with the hyperbolic periodic orbit $u(t,\mu)$.

To verify that the homoclinic orbit is transversal when $\mu\neq 0$, we use the fact that the Crandall–Rabinowitz theorem also tells us that the operator $F_z(\gamma(\mu),\xi(\mu),\eta(\mu),\mu)$ is invertible when $\mu\neq 0$.

As in the proof of Theorem 5.1, we find that

$$w \in T_{x(0,\mu)}W^s(u_\mu) \cap T_{x(0,\mu)}W^u(u_\mu)$$

if and only if there exist $(\gamma_1, \xi) \in \mathbf{R} \times \mathcal{R}(P_+)$ and $(\gamma_2, \eta) \in \mathbf{R} \times \mathcal{R}(Q_-)$ such that

$$\begin{aligned} w &= \gamma_1 f\bigl(x(0,\mu),\mu\bigr) + x_\xi^+\bigl(-mT + \gamma(\mu), \xi(\mu), \mu\bigr)\xi \\ &= \gamma_2 f\bigl(x(0,\mu),\mu\bigr) + x_\eta^-\bigl(mT + \gamma^-, \eta(\mu), \mu\bigr)\eta \end{aligned}$$

and that then

$$F_z\bigl(\gamma(\mu), \xi(\mu), \eta(\mu), \mu\bigr)(\gamma_1 - \gamma_2, \xi, \eta) = 0.$$

However, when $\mu \neq 0$, this derivative is invertible and hence one to one. So $(\gamma_1 - \gamma_2, \xi, \eta) = 0$ and $w = \gamma_1 f(x(0,\mu),\mu)$. Thus, when $\mu \neq 0$,

$$T_{x(0,\mu)}W^s(u_\mu) \cap T_{x(0,\mu)}W^u(u_\mu) = \operatorname{span}\bigl\{f\bigl(x(0,\mu),\mu\bigr)\bigr\}$$

and so $x(t,\mu)$ is a transversal homoclinic orbit. Thus we have proved the theorem. □

EXAMPLE 6.2. Suppose $F : U \to \mathbf{R}^2$ is a C^4 vector field such that

$$\dot{x} = F(x)$$

has a hyperbolic periodic solution $r(t)$ with minimal period T and $g : \mathbf{R}^2 \to \mathbf{R}^2$ is a C^4 vector field such that 0 is a saddle point of

$$\dot{y} = g(y)$$

and $\zeta(t)$ is an associated homoclinic orbit. Then $(r(t), 0)$ is a hyperbolic periodic orbit of the system

$$\dot{x} = F(x), \qquad \dot{y} = g(y)$$

and $p(t,\beta) = (r(t), \zeta(t+\beta))$ is a nontransversal homoclinic orbit with asymptotic phases $\gamma^+ = \gamma^- = 0$ such that the subspace of bounded solutions of the variational system

$$\dot{x} = F'\bigl(r(t)\bigr)x, \qquad \dot{y} = g'\bigl(\zeta(t)\bigr)y$$

is spanned by $(r'(t), 0)$ and $(0, \zeta'(t))$.

Let $\psi(t)$ be, up to a scalar multiple, the unique bounded solution of

$$\dot{y} = -g'\bigl(\zeta(t)\bigr)^* y.$$

Then $(0, \psi(t))$ is, up to a scalar multiple, the unique solution of

$$\dot{x} = -F'\big(r(t)\big)^* x, \qquad \dot{y} = -g'\big(\zeta(t)\big)^* y$$

which tends to 0 as $|t| \to \infty$.

Then it follows from Theorem 6.1 that if the Melnikov function

$$d(\beta) = \int_{-\infty}^{\infty} \psi^*(t+\beta) g_1\big(r(t), \zeta(t+\beta), 0\big)\, \mathrm{d}t$$

has a simple zero at $\beta = 0$, then for $\mu \neq 0$ sufficiently small, the perturbed C^4 system

$$\dot{x} = F(x) + \mu F_1(x, y, \mu), \qquad \dot{y} = g(y) + \mu g_1(x, y, \mu)$$

has a transversal homoclinic orbit associated with a hyperbolic periodic orbit.

Now we give an explicit example of this situation.

EXAMPLE 6.3. The planar autonomous system $\dot{x} = F(x)$ given by

$$\dot{x}_1 = -x_1 + x_2 + \frac{x_1}{\sqrt{x_1^2 + x_2^2}}, \qquad \dot{x}_2 = -x_1 - x_2 + \frac{x_2}{\sqrt{x_1^2 + x_2^2}}$$

has the periodic solution $r(t) = (\cos t, -\sin t)$. One calculates the trace $\operatorname{Tr} DF(r(t)) = -1$. Then, by Jacobi's formula, the product of the Floquet multipliers is

$$\mathrm{e}^{\int_0^{2\pi} \operatorname{Tr} DF(r(t))\, \mathrm{d}t} = \mathrm{e}^{-2\pi}.$$

Since one Floquet multiplier is 1, the other must be $\mathrm{e}^{-2\pi}$. So $r(t)$ is hyperbolic.

Next $(0, 0)$ is a saddle for the system

$$\dot{y}_1 = y_2, \qquad \dot{y}_2 = y_1 - 2y_1^3$$

with associated saddle connexion $\zeta(t) = (\xi(t), \dot{\xi}(t))$ where $\xi(t) = \operatorname{sech} t$. Note that $\psi(t) = (\ddot{\xi}(t), -\dot{\xi}(t))$ is a bounded solution of the system adjoint to the variational equation along $\zeta(t)$.

Following Example 6.2, we apply Theorem 6.1 to the system

$$\begin{aligned}
\dot{x}_1 &= -x_1 + x_2 + \frac{x_1}{\sqrt{x_1^2 + x_2^2}}, \\
\dot{x}_2 &= -x_1 - x_2 + \frac{x_2}{\sqrt{x_1^2 + x_2^2}}, \\
\dot{y}_1 &= y_2 + \mu x_1, \\
\dot{y}_2 &= y_1 - 2y_1^3 + \mu x_2.
\end{aligned} \tag{52}$$

The Melnikov function is

$$\begin{aligned} d(\beta) &= \int_{-\infty}^{\infty} \dot{\xi}(t+\beta)\sin t + \ddot{\xi}(t+\beta)\cos t \, \mathrm{d}t \\ &= \int_{-\infty}^{\infty} \dot{\xi}(t)\sin(t-\beta) + \ddot{\xi}(t)\cos(t-\beta)\, \mathrm{d}t \\ &= \int_{-\infty}^{\infty} \dot{\xi}(t)(\sin t\cos\beta - \cos t\sin\beta) + \ddot{\xi}(t)(\cos t\cos\beta + \sin t\sin\beta)\, \mathrm{d}t \\ &= I_1\cos\beta + I_2\sin\beta, \end{aligned}$$

where

$$I_1 = \int_{-\infty}^{\infty} \dot{\xi}(t)\sin t + \ddot{\xi}(t)\cos t\, \mathrm{d}t \quad \text{and} \quad I_2 = \int_{-\infty}^{\infty} -\dot{\xi}(t)\cos t + \ddot{\xi}(t)\sin t\, \mathrm{d}t.$$

Note that $I_2 = 0$ since its integrand is odd. We calculate

$$\begin{aligned} I_1 &= \int_{-\infty}^{\infty} -\frac{\mathrm{d}}{\mathrm{d}t}\big(\dot{\xi}(t)\cos t\big) + 2\ddot{\xi}(t)\cos t\, \mathrm{d}t \\ &= 2\int_{-\infty}^{\infty} \ddot{\xi}(t)\cos t\, \mathrm{d}t \\ &= 2\bigg(\dot{\xi}(t)\cos t|_{-\infty}^{\infty} - \int_{-\infty}^{\infty} \dot{\xi}(t)(-\sin t)\, \mathrm{d}t\bigg) \\ &= 2\int_{-\infty}^{\infty} \dot{\xi}(t)\sin t\, \mathrm{d}t \\ &= 2\bigg(\xi(t)\sin t|_{-\infty}^{\infty} - \int_{-\infty}^{\infty} \xi(t)\cos t\, \mathrm{d}t\bigg) \\ &= -2\int_{-\infty}^{\infty} \xi(t)\cos t\, \mathrm{d}t \end{aligned}$$

and so

$$I_1 = -2\int_{-\infty}^{\infty} \operatorname{sech} t\cos t\, \mathrm{d}t \neq 0.$$

Hence we have shown that

$$d(\beta) = I_1\cos\beta,$$

where $I_1 \neq 0$. It is clear that this function has simple zeros and hence we may conclude that, for μ nonzero and sufficiently small, system (52) has a hyperbolic periodic orbit with associated transversal homoclinic orbit.

7. Finding transversal periodic-to-periodic homoclinic orbits through numerical shadowing

In this last section, which is based on [4], we show how transversal periodic-to-periodic homoclinic orbits can be constructed via numerical shadowing. As usual, we consider the differential equation

$$\dot{x} = f(x) \tag{53}$$

where now f is a C^2 vector field in $\mathbf{R}^n$ with

$$\left|f(x)\right| \leqslant M_0, \quad \left|f'(x)\right| \leqslant M_1, \quad \left|f''(x)\right| \leqslant M_2.$$

Denote by $\phi^t(x)$ the corresponding flow.

First we define pseudo (or approximate) orbits, which are obtained when an orbit is computed numerically.

DEFINITION 7.1. A sequence $\{w_k\}_{k=-\infty}^{+\infty}$ with associated times $\{h_k\}_{k=-\infty}^{+\infty}$ is said to be a δ *pseudo orbit* of (53) if

$$\sup_{k\in Z} h_k < \infty, \qquad \inf_{k\in Z} h_k > 0$$

and for all k

$$f(w_k) \neq 0, \qquad \left|w_{k+1} - \phi^{h_k}(w_k)\right| \leqslant \delta.$$

We look for a true orbit near a pseudo orbit. Such a true orbit is said to shadow the pseudo orbit.

DEFINITION 7.2. A sequence $\{x_k\}_{k=-\infty}^{+\infty}$ with associated times $\{t_k\}_{k=-\infty}^{+\infty}$ is said to ε *shadow* a δ pseudo orbit $\{w_k\}_{k=-\infty}^{+\infty}$ with associated times $\{h_k\}_{k=-\infty}^{+\infty}$ if for all k, $x_{k+1} = \phi^{t_k}(x_k)$ and

$$|x_k - w_k| \leqslant \varepsilon, \qquad |t_k - h_k| \leqslant \varepsilon.$$

We are interested in finding homoclinic orbits associated to periodic orbits. There are particular kinds of pseudo orbits associated with these. First we define pseudo periodic orbits.

DEFINITION 7.3. A δ pseudo orbit $\{y_k\}_{k=-\infty}^{+\infty}$ with associated times $\{\ell_k\}_{k=-\infty}^{+\infty}$ is said to be a δ *pseudo periodic orbit* with period N of (53) if for all k

$$y_{k+N} = y_k, \qquad \ell_{k+N} = \ell_k.$$

Normally we expect pseudo periodic orbits to be shadowed by discrete true periodic orbits, that is, we expect x_k and t_k to satisfy

$$x_{k+N} = x_k, \qquad t_{k+N} = t_k$$

for all k.

Next we define pseudo homoclinic orbits.

DEFINITION 7.4. Let $\{y_k\}_{k=-\infty}^{+\infty}$ be a δ pseudo periodic orbit with associated times $\{\ell_k\}_{k=-\infty}^{+\infty}$ and period N. A δ pseudo orbit $\{w_k\}_{k=-\infty}^{+\infty}$ with associated times $\{h_k\}_{k=-\infty}^{+\infty}$ is said to be a δ *pseudo homoclinic orbit* if for some τ, $0 \leqslant \tau < N$,

$$w_k = y_{k+\tau}, \quad h_k = \ell_{k+\tau} \quad \text{for } k \leqslant p, \qquad w_k = y_k, \quad h_k = \ell_k \quad \text{for } k \geqslant q$$

for some integers $p < q$.

Note that τ allows for the possibility of homoclinic orbits with different forward and backward asymptotic phases.

In preparation for the statement of the main theorem, we define a linear operator associated with a pseudo orbit. Consider a fixed pseudo orbit $\{w_k\}_{k=-\infty}^{+\infty}$ with associated times $\{h_k\}_{k=-\infty}^{+\infty}$. For each k, let Y_{w_k} be the subspace of $\mathbf{R}^n$ consisting of the vectors orthogonal to $f(w_k)$. Let Y_w be the Banach space of bounded sequences $\mathbf{v} = \{v_k\}_{k\in Z}$ with $v_k \in Y_{w_k}$, and equip Y_w with the norm

$$\|\mathbf{v}\| = \sup_{k\in Z} |v_k|.$$

Also, let $\tilde{Y}_w$ be a similar Banach space except that $v_k \in Y_{w_{k+1}}$.

Then let $L_w : Y_w \to \tilde{Y}_w$ be the linear operator defined by

$$(L_w \mathbf{v})_k = v_{k+1} - P_{w_{k+1}} D\phi^{h_k}(w_k) v_k,$$

where if $f(x) \neq 0$, the operator $P_x : \mathbf{R}^n \to \mathbf{R}^n$ is the orthogonal projection defined by

$$P_x v = v - \frac{f(x)^* v}{|f(x)|^2} f(x).$$

L_w represents the action of the derivative of the flow along the pseudo orbit projected on to the subspace orthogonal to the vector field.

Now we are ready to state the main theorem in this section, which gives conditions under which a pseudo homoclinic orbit is shadowed by a true homoclinic orbit.

THEOREM 7.5. *Suppose* $f : \mathbf{R}^n \to \mathbf{R}^n$ *is a* C^2 *vectorfield. Let* $\{y_k\}_{k=-\infty}^{+\infty}$ *be a* δ *pseudo periodic orbit with period* N *of* (53) *and let* $\{w_k\}_{k=-\infty}^{+\infty}$ *be a* δ *pseudo homoclinic* *orbit with associated times* $\{h_k\}_{k=-\infty}^{+\infty}$ *connecting* $\{y_{k+\tau}\}_{k=-\infty}^{\infty}$ *to* $\{y_k\}_{k=-\infty}^{+\infty}$ *such that* $\Delta = \inf_{k\in Z} |f(w_k)| > 0$ *and the operator* L_w *is invertible.*

Then there exist constants C *and* δ_0 *depending only on* f, $\|L_w^{-1}\|$, Δ, $h_{\max}$ *and* $h_{\min}$, *where*

$$h_{\max} = \sup_{k\in Z} h_k, \qquad h_{\min} = \inf_{k\in Z} h_k,$$

such that if $\delta < \delta_0$,

(i) *the pseudo periodic orbit* $\{y_k\}_{k=-\infty}^{+\infty}$ *is shadowed by a true discrete periodic orbit* $\{x_k\}_{k=-\infty}^{\infty}$ *such that for all* k

$$f(y_k)^*(x_k - y_k) = 0, \quad |x_k - y_k| \leqslant C\delta.$$

Moreover, the periodic orbit $\phi^t(x_0)$ *is hyperbolic*;

(ii) *The pseudo connecting orbit* $\{w_k\}_{k=-\infty}^{+\infty}$ *is shadowed by a true orbit* $\{z_k\}_{k=-\infty}^{\infty}$ *such that for all* k

$$f(w_k)^*(z_k - w_k) = 0, \quad |z_k - w_k| \leqslant C\delta.$$

Moreover, $\phi^t(z_0)$ *is hyperbolic as in Definition* 4.3 *and* $\operatorname{dist}(\phi^t(z_0), \mathrm{O}(x_0)) \to 0$ *as* $|t| \to \infty$, *where* $\mathrm{O}(x_0)$ *is the orbit of* x_0.

Furthermore, suppose there is r *such that for* $k = 0, \dots, N-1$

$$|w_r - y_k| > \bigl(\bigl|f(y_k)\bigr| + M_1 C\delta\bigr)\frac{\mathrm{e}^{M_1(h_{\max}+C\delta)} - 1}{M_1} + 2C\delta, \tag{54}$$

where $M_1 = \sup_{x\in\mathbf{R}^n} |f'(x)|$. *Then* z_r *and* x_r *lie on distinct orbits and so we may conclude that* $\phi^t(z_0)$ *is a transversal homoclinic orbit associated with the periodic orbit* $\phi^t(x_0)$.

To prove the theorem, we need the following lemmas. The first is a Newton–Kantorovich type of result.

LEMMA 7.6. *Let* X, Y *be Banach spaces and* $\mathcal{G}: X \to Y$ *a* C^2 *function. Suppose* $\mathbf{y}$ *is an element of* X *for which*

$$\bigl\|\mathcal{G}(\mathbf{y})\bigr\| \leqslant \delta$$

and $D\mathcal{G}(\mathbf{y}) = L$ *is invertible with* $\|L^{-1}\| \leqslant K$. *Set*

$$M = \sup\bigl\{\bigl\|D^2\mathcal{G}(\mathbf{x})\bigr\|: \mathbf{x} \in X,\ \|\mathbf{x} - \mathbf{y}\| \leqslant 2K\delta\bigr\}.$$

Then if

$$2MK^2\delta < 1,$$

there is a unique solution $\mathbf{x}$ *of the equation*

$$\mathcal{G}(\mathbf{x}) = \mathbf{0}$$

satisfying $\|\mathbf{x} - \mathbf{y}\| \leqslant 2K\delta$.

PROOF. Define the operator $F : X \to X$ by

$$F(\mathbf{x}) = \mathbf{y} - L^{-1}\big[\mathcal{G}(\mathbf{x}) - D\mathcal{G}(\mathbf{y})(\mathbf{x} - \mathbf{y})\big].$$

Clearly $\mathcal{G}(\mathbf{x}) = \mathbf{0}$ if and only if $F(\mathbf{x}) = \mathbf{x}$. Moreover, if $\|\mathbf{x} - \mathbf{y}\| \leqslant \varepsilon = 2K\delta$,

$$\begin{aligned} \big\|F(\mathbf{x}) - \mathbf{y}\big\| &\leqslant \|L^{-1}\| \big\|\mathcal{G}(\mathbf{x}) - \mathcal{G}(\mathbf{y}) - D\mathcal{G}(\mathbf{y})(\mathbf{x} - \mathbf{y}) + \mathcal{G}(\mathbf{y})\big\| \\ &\leqslant K\left[\frac{1}{2}M\|\mathbf{x} - \mathbf{y}\|^2 + \delta\right] \\ &\leqslant MK\varepsilon \cdot \frac{1}{2}\varepsilon + \frac{1}{2}\varepsilon \\ &< \varepsilon. \end{aligned}$$

Furthermore, if $\|\mathbf{x} - \mathbf{y}\| \leqslant \varepsilon$ and $\|\mathbf{z} - \mathbf{y}\| \leqslant \varepsilon$, then

$$\big\|F(\mathbf{x}) - F(\mathbf{z})\big\| \leqslant \|L^{-1}\| \big\|\mathcal{G}(\mathbf{x}) - \mathcal{G}(\mathbf{z}) - D\mathcal{G}(\mathbf{y})(\mathbf{x} - \mathbf{z})\big\| \leqslant KM\varepsilon\|\mathbf{x} - \mathbf{z}\|.$$

Since $KM\varepsilon < 1$, F is a contraction on the closed ball of radius ε, centre $\mathbf{y}$, and thus the lemma follows from the contraction mapping principle. ☐

We use this lemma to prove a second lemma, which gives a condition under which a pseudo orbit is shadowed by a true orbit.

LEMMA 7.7. *Let* $\{w_k\}_{k=-\infty}^{+\infty}$ *be a bounded* δ *pseudo orbit of* (53) *with associated times* $\{h_k\}_{k=-\infty}^{+\infty}$ *such that* $\Delta = \inf_{k\in Z} |f(w_k)| > 0$ *and* L_w *is invertible with* $\|L_w^{-1}\| \leqslant K$. *Then there exist constants* C, δ_0 *depending only on* f, K, Δ, $h_{\max}$ *and* $h_{\min}$, *where*

$$h_{\max} = \sup_{k\in Z} h_k, \qquad h_{\min} = \inf_{k\in Z} h_k,$$

such that if $\delta < \delta_0$ *there is a unique true orbit* $\{x_k\}_{k=-\infty}^{+\infty}$ *of* (53) *with associated times* $\{t_k\}_{k=-\infty}^{+\infty}$ *such that for* $k \in Z$

$$f(w_k)^*(x_k - w_k) = 0, \quad |x_k - w_k| \leqslant C\delta, \quad |t_k - h_k| \leqslant C\delta.$$

Moreover, the orbit $\phi^t(x_0)$ *is not an equilibrium and is hyperbolic in the sense of Definition* 4.3.

PROOF. In order to prove the existence and uniqueness of the orbit $\{x_k\}_{k=-\infty}^{+\infty}$, let X be the Banach space $Y_w \times \ell^\infty(Z, \mathbf{R})$ with the maximum norm (note: we use the Euclidean norm in $\mathbf{R}^n$). So we define

$$\big\|(\mathbf{z}, \mathbf{t})\big\| = \max\big\{\|\mathbf{z}\|, \|\mathbf{t}\|\big\},$$

for $(\mathbf{z}, \mathbf{t}) = (\{z_k\}_{k=-\infty}^{+\infty}, \{t_k\}_{k=-\infty}^{+\infty}) \in X$, where

$$\|\mathbf{z}\| = \sup_{k\in Z} |z_k|, \qquad \|\mathbf{t}\| = \sup_{k\in Z} |t_k|.$$

Then we define $\mathcal{G} : X \to \ell^\infty(Z, \mathbf{R}^n)$ by

$$\big[\mathcal{G}(\mathbf{z}, \mathbf{t})\big]_k = w_{k+1} + z_{k+1} - \phi^{t_k}(w_k + z_k).$$

We seek a solution $(\mathbf{z}, \mathbf{t})$ of the equation

$$\mathcal{G}(\mathbf{z}, \mathbf{t}) = \mathbf{0}$$

such that

$$\|\mathbf{z}\| \leqslant C\delta, \qquad \|\mathbf{t} - \mathbf{h}\| \leqslant C\delta,$$

where $\mathbf{h} = \{h_k\}_{k=-\infty}^{\infty}$ and C is to be determined. We apply Lemma 7.6. To this end, note that

$$\big\|\mathcal{G}(\mathbf{0}, \mathbf{h})\big\| \leqslant \delta.$$

Next note that the derivative of $\mathcal{G}$ at $(\mathbf{0}, \mathbf{h})$ is given for $(\mathbf{u}, \mathbf{s}) \in X$ by

$$\big[D\mathbf{G}(\mathbf{0}, \mathbf{h})(\mathbf{u}, \mathbf{s})\big]_k = u_{k+1} - f\big(\phi^{h_k}(w_k)\big)s_k - D\phi^{h_k}(w_k)u_k.$$

We approximate this operator by the operator T given by

$$\big[T(\mathbf{u}, \mathbf{s})\big]_k = u_{k+1} - f(w_{k+1})s_k - D\phi^{h_k}(w_k)u_k.$$

First we show that T is invertible. To do this, we must show that for all $\mathbf{g} = \{g_k\}_{k=-\infty}^{+\infty}$ in $\ell^\infty(Z, \mathbf{R}^n)$, there is a unique solution of the equation

$$T(\mathbf{u}, \mathbf{s}) = \mathbf{g},$$

that is,

$$u_{k+1} - f(w_{k+1})s_k - D\phi^{h_k}(w_k)u_k = g_k, \quad k \in Z. \tag{55}$$

We can solve (55) for s_k by multiplying both sides by $f(w_{k+1})^*$ to get

$$s_k = -\frac{f(w_{k+1})^*}{|f(w_{k+1})|^2}\bigl\{D\phi^{h_k}(w_k)u_k + g_k\bigr\}, \quad k \in Z \tag{56}$$

and we obtain the estimate

$$\|\mathbf{s}\| \leqslant \Delta^{-1}\bigl[\mathrm{e}^{M_1 h_{\max}}\|\mathbf{u}\| + \|\mathbf{g}\|\bigr], \tag{57}$$

where

$$M_1 = \sup_{x\in\mathbf{R}^n}\bigl|f'(x)\bigr|.$$

Substituting (56) in (55) and rearranging, we obtain the equation

$$(L_w\mathbf{u})_k = \bar{g}_k, \tag{58}$$

where $\mathbf{u} = \{u_k\}_{k=-\infty}^{\infty} \in Y_w$ and the sequence $\bar{\mathbf{g}} = \{\bar{g}_k\}_{k=-\infty}^{\infty}$ is given by

$$\bar{g}_k = g_k - \frac{f(w_{k+1})^* g_k}{|f(w_{k+1})|^2} f(w_{k+1}) = P_{w_{k+1}} g_k, \quad k \in Z,$$

and so is in $\tilde{Y}_w$. Since L_w is invertible, we may solve (58) to get

$$\mathbf{u} = L_w^{-1}\bar{\mathbf{g}}. \tag{59}$$

So (55) has a unique solution $(\mathbf{u}, \mathbf{s})$ given by (59) and (56) with

$$\|\mathbf{u}\| \leqslant \|L_w^{-1}\|\|\bar{\mathbf{g}}\| \leqslant K\|\mathbf{g}\|$$

and $\|\mathbf{s}\|$ satisfying the inequality in (57). It follows that T is invertible with

$$\|T^{-1}\| \leqslant C_1 = \max\bigl\{\Delta^{-1}(\mathrm{e}^{M_1 h_{\max}}K + 1), K\bigr\}.$$

Now observe that

$$\bigl\|D\mathcal{G}(\mathbf{0}, \mathbf{h}) - T\bigr\| \leqslant M_1\delta.$$

Then if

$$M_1 C_1 \delta \leqslant 1/2,$$

it follows that $D\mathcal{G}(\mathbf{0}, \mathbf{h})$ is also invertible and

$$\bigl\|D\mathcal{G}(\mathbf{0}, \mathbf{h})^{-1}\bigr\| \leqslant C/2,$$

where

$$C = 4C_1.$$

Next if $\mathbf{v} = (\{z_k\}_{k=-\infty}^{+\infty}, \{t_k\}_{k=-\infty}^{+\infty})$, $\mathbf{u} = (\{\tau_k\}_{k=-\infty}^{\infty}, \{\xi_k\}_{k=-\infty}^{\infty})$, and $\bar{\mathbf{u}} = (\{\sigma_k\}_{k=-\infty}^{\infty}, \{\eta_k\}_{k=-\infty}^{\infty})$, one calculates, for $k = 0, \ldots, N$, that

$$\begin{aligned}\left[D^2\mathcal{G}(\mathbf{v})\mathbf{u}\bar{\mathbf{u}}\right]_k = {} & -\tau_k\sigma_k f'\left(\varphi^{t_k}(w_k + z_k)\right) f\left(\varphi^{t_k}(w_k + z_k)\right) \\ & - \tau_k f'\left(\varphi^{t_k}(w_k + z_k)\right) D\varphi^{t_k}(w_k + z_k)\eta_k \\ & - \sigma_k f'\left(\varphi^{t_k}(w_k + z_k)\right) D\varphi^{t_k}(w_k + z_k)\xi_k \\ & - D^2\varphi^{t_k}(w_k + z_k)\xi_k\eta_k.\end{aligned}$$

We use the following estimates, which follow easily from Gronwall's lemma and the variation of constants formula

$$\left\|D\varphi^t(\mathbf{x})\right\| \leqslant \mathrm{e}^{M_1 t}, \qquad \left\|D^2\varphi^t(\mathbf{x})\right\| \leqslant M_2 t \mathrm{e}^{2M_1 t}$$

where

$$M_2 = \sup_{x \in \mathbf{R}^n} \left|f''(x)\right|.$$

It follows that

$$\left\|D^2\mathcal{G}(\mathbf{z}, \mathbf{t})\right\| \leqslant M_3, \tag{60}$$

where

$$M_3 = M_0 M_1 + 2M_1 \mathrm{e}^{M_1(h_{\max} + C\delta)} + M_2(h_{\max} + C\delta)\mathrm{e}^{2M_1(h_{\max} + C\delta)}.$$

Then provided

$$M_3 C^2 \delta < 2,$$

Lemma 7.6 can be applied and we get a unique solution $(\mathbf{z}, \mathbf{t})$ of $\mathcal{G}(\mathbf{z}, \mathbf{t}) = 0$ with $\|\mathbf{z}\| \leqslant C\delta$, $\|\mathbf{t}\| \leqslant C\delta$. Then with $x_k = w_k + z_k$, the first part of the lemma follows.

In the rest of the proof we also assume that

$$M_1 C\delta < \Delta.$$

Then we observe that

$$\left|f(x_k)\right| \geqslant \left|f(w_k)\right| - \left|f(w_k) - f(x_k)\right| \geqslant \Delta - M_1 C\delta > 0$$

so that the orbit $\phi^t(x_0)$ is not an equilibrium.

Now we show that $\phi^t(x_0)$ is hyperbolic. First note that the derivative of $\mathcal{G}$ at $(\mathbf{z},\mathbf{t})$, where $\mathbf{z}=\{x_k-w_k\}_{k=-\infty}^{\infty}$, is given for $(\mathbf{u},\mathbf{s})\in X$ by

$$\big[D\mathbf{G}(\mathbf{z},\mathbf{t})(\mathbf{u},\mathbf{s})\big]_k=u_{k+1}-f(x_{k+1})s_k-D\phi^{t_k}(x_k)u_k.$$

In view of (60),

$$\big\|D\mathbf{G}(\mathbf{z},\mathbf{t})-D\mathbf{G}(\mathbf{0},\mathbf{h})\big\|\leqslant M_3\big\|(\mathbf{z},\mathbf{t})-(\mathbf{0},\mathbf{h})\big\|\leqslant M_3C\delta.$$

Since $\|D\mathbf{G}(\mathbf{0},\mathbf{h})^{-1}\|\leqslant C/2$ and $M_3C\delta(C/2)<1$, it follows that $D\mathbf{G}(\mathbf{z},\mathbf{t})$ is invertible. In particular, this implies that for all bounded sequences $g_k\in Y_{w_{k+1}}$, the equation

$$v_{k+1}-f(x_{k+1})s_k-D\phi^{t_k}(x_k)v_k=g_k,\quad k\in Z \tag{61}$$

has a unique bounded solution $v_k\in Y_{w_k}$ and $s_k\in\mathbf{R}$. Note that

$$f(w_{k+1})^*f(x_{k+1})\geqslant\big|f(w_{k+1})\big|\big[\big|f(w_{k+1})\big|-M_1C\delta\big]>0.$$

Multiplying (61) by $f(w_{k+1})^*$, we obtain

$$s_k=-\frac{f(w_{k+1})^*D\phi^{t_k}(x_k)v_k}{f(w_{k+1})^*f(x_{k+1})},\quad k\in Z. \tag{62}$$

Then substituting this back in (61), we obtain

$$v_{k+1}=P_{x_{k+1}}D\phi^{t_k}(x_k)v_k+g_k,\quad k\in Z.$$

The upshot is that for all bounded sequences $g_k\in Y_{w_{k+1}}$, the equation

$$v_{k+1}-P_{x_{k+1}}D\phi^{t_k}(x_k)v_k=g_k \tag{63}$$

has a bounded solution $v_k\in Y_{w_k}$. Moreover, it must be unique for if v_k is a bounded solution of (63) and we define s_k by (62), then we see that s_k and v_k form a bounded solution of (61). So it follows that the difference equation

$$v_{k+1}=P_{x_{k+1}}D\phi^{t_k}(x_k)v_k \tag{64}$$

has an exponential dichotomy on Z (see [12,24]).

Now we want to apply Proposition 2.9 with $A(t)=f'(\phi^t(x_0))$ so that $X(t)=D\phi^t(x_0)$, $x_0(t)=f(\phi^t(x_0))$ and with $Q_k=P_{x_k}$ and s_k defined recursively by $s_0=0$ and $s_{k+1}=s_k+t_k$. Now, provided that

$$C\delta<h_{\min},$$

we have

$$0 < h_{\min} - C\delta \leqslant t_k \leqslant h_{\max} + C\delta < \infty.$$

Also note that $|f(\phi^t(x_0))| \leqslant M_0$ for all t. Next given any real t there exists k such that $s_k \leqslant t < s_{k+1}$. Then

$$\begin{aligned}\left|f(x_k)\right| = \left|f\left(\phi^{s_k}(x_0)\right)\right| &= \left|D\phi^{s_k-t}\left(\phi^t(x_0)\right)f\left(\phi^t(x_0)\right)\right| \\ &\leqslant \mathrm{e}^{M_1(h_{\max}+C\delta)}\left|f\left(\phi^t(x_0)\right)\right|\end{aligned}$$

so that since $0 < \Delta - M_1C\delta \leqslant |f(x_k)|$ it follows that for all t

$$\left|f\left(\phi^t(x_0)\right)\right| \geqslant \mathrm{e}^{-M_1(h_{\max}+C\delta)}(\Delta - M_1C\delta) > 0.$$

Then, since (64) can be written as $v_{k+1} = Q_{k+1}X(s_{k+1})X^{-1}(s_k)v_k$ with $v_k \in \mathcal{R}(Q_k)$, it follows from Proposition 2.9 that

$$\dot{x} = f'\left(\phi^t(x_0)\right)x$$

has a trichotomy and so by Proposition 4.4 the solution $\phi^t(x_0)$ is hyperbolic.

This completes the proof of the lemma with δ_0 as the largest $\delta > 0$ such that

$$M_3C^2\delta \leqslant 2, \quad M_1C_1\delta \leqslant 1/2, \quad M_1C\delta \leqslant \Delta, \quad C\delta \leqslant h_{\min}. \tag{65}$$

□

In the next lemma we show under a uniqueness condition that an orbit which shadows a pseudo homoclinic orbit is asymptotic to it.

LEMMA 7.8. *Let* $\{w_k\}_{k=-\infty}^{+\infty}$ *be a pseudo orbit of* (53) *with associated times* $\{h_k\}_{k=-\infty}^{+\infty}$ *and suppose it is* ε *shadowed by a true orbit* $\{z_k\}_{k=-\infty}^{+\infty}$ *with associated times* $\{s_k\}_{k=-\infty}^{+\infty}$ *such that for all* k

$$f(w_k)^*(z_k - w_k) = 0.$$

Next let $\{y_k\}_{k=-\infty}^{+\infty}$ *be a pseudo periodic orbit with associated times* $\{\ell_k\}_{k=-\infty}^{+\infty}$ *and suppose it is* ε *shadowed by a unique true orbit* $\{x_k\}_{k=-\infty}^{+\infty}$ *with associated times* $\{t_k\}_{k=-\infty}^{+\infty}$ *such that for all* k

$$f(y_k)^*(x_k - y_k) = 0.$$

Suppose also that

$$w_k = y_k, \quad h_k = \ell_k \quad \textit{for } k \geqslant q.$$

Then

$$|z_k - x_k| + |s_k - t_k| \to 0 \quad \text{as } k \to \infty.$$

PROOF. Let $\{y_k\}_{k=-\infty}^{+\infty}$ have period N. Since for all k

$$f(y_k)^*(x_{k+N} - y_k) = f(y_{k+N})^*(x_{k+N} - y_{k+N}) = 0,$$

and

$$|x_{k+N} - y_k| = |x_{k+N} - y_{k+N}| \leqslant \varepsilon, \qquad |t_{k+N} - \ell_k| = |t_{k+N} - \ell_{k+N}| \leqslant \varepsilon$$

also, it follows by uniqueness that $x_{k+N} = x_k$ and $t_{k+N} = t_k$ for all k.

Define for $j \geqslant 0$ and all k

$$z_k^{(j)} = z_{k+jN}, \qquad s_k^{(j)} = s_{k+jN}.$$

We claim that for any fixed k

$$z_k^{(j)} \to x_k, \qquad s_k^{(j)} \to t_k$$

as $j \to \infty$. Suppose not. Then there exists $i, \eta > 0$ and a sequence $j_r \to \infty$ as $r \to \infty$ such that

$$|z_i^{(j_r)} - x_i| + |s_i^{(j_r)} - t_i| \geqslant \eta \tag{66}$$

for all r. By taking a further subsequence if necessary, we can assume that for each k

$$z_k^{(j_r)} \to \tilde{x}_k, \qquad s_k^{(j_r)} \to \tilde{t}_k$$

as $r \to \infty$. Now, for all k and r, $\phi^{s_k^{(j_r)}}(z_k^{(j_r)}) = z_{k+1}^{(j_r)}$ and for fixed k, if r is large enough,

$$|z_k^{(j_r)} - y_k| = |z_k^{(j_r)} - y_{k+j_rN}| = |z_{k+j_rN} - w_{k+j_rN}| \leqslant \varepsilon$$

and, similarly,

$$|s_k^{(j_r)} - \ell_k| \leqslant \varepsilon.$$

Also for fixed k, if r is large enough,

$$f(y_k)^*(z_k^{(j_r)} - y_k) = 0.$$

So, letting $r \to \infty$, we obtain that for all k, $\phi^{\tilde{t}_k}(\tilde{x}_k) = \tilde{x}_{k+1}$ and

$$|\tilde{x}_k - y_k| \leqslant \varepsilon, \quad |\tilde{t}_k - \ell_k| \leqslant \varepsilon, \quad f(y_k)^*(\tilde{x}_k - y_k) = 0.$$

By uniqueness, it follows that for all k, $\tilde{x}_k = x_k$ and $\tilde{t}_k = t_k$. Hence for each k

$$z_k^{(j_r)} \to x_k, \qquad s_k^{(j_r)} \to t_k$$

as $r \to \infty$. This contradicts (66). So we deduce that for each k

$$z_{k+jN} = z_k^{(j)} \to x_k \quad \text{and} \quad s_{k+jN} = s_k^{(j)} \to t_k \quad \text{as } j \to \infty.$$

It follows that

$$z_k - x_k \to 0 \quad \text{and} \quad s_k - t_k \to 0 \quad \text{as } k \to \infty. \qquad \square$$

PROOF OF THEOREM 7.5. We take δ_0 to be the largest δ satisfying the inequalities in (65) with $K = \|L_w^{-1}\|$.

Now let Y_y be the Banach space of bounded sequences $\mathbf{v} = \{v_k\}_{k\in Z}$ with $v_k \in \mathbf{R}^n$ and orthogonal to $f(y_k)$, Y_y being equipped with the norm

$$\|\mathbf{v}\| = \sup_{k\in Z} |v_k|$$

and let $\tilde{Y}_y$ be a similar Banach space but with v_k orthogonal to $f(y_{k+1})$. Then let $L_y : Y_y \to \tilde{Y}_y$ be the linear operator defined by

$$(L_y\mathbf{v})_k = v_{k+1} - P_{y_{k+1}} D\phi^{\ell_k}(y_k)v_k,$$

where $\{\ell_k\}_{k=-\infty}^{+\infty}$ are the times associated with $\{y_k\}_{k=-\infty}^{+\infty}$. By hypothesis, L_w is invertible. We now show that L_y is invertible and that

$$\|L_y^{-1}\| \leqslant \|L_w^{-1}\|.$$

Let $\mathbf{g} = \{g_k\}_{-\infty}^{\infty} \in \tilde{Y}_y$ and r a natural number. Then, since L_w is invertible, the difference equation

$$v_{k+1} = P_{w_{k+1}} D\phi^{h_k}(w_k)v_k + P_{w_{k+1}} g_{k-rN}, \quad k \in Z$$

has a solution $v_k^{(r)} \in Y_{w_k}$ such that for all k

$$|v_k^{(r)}| \leqslant \|L_w^{-1}\| \|\mathbf{g}\|.$$

Take

$$u_k^{(r)} = v_{k+rN}^{(r)}.$$

Then $u_k^{(r)} \in Y_{w_{k+rN}}$ is a solution of

$$u_{k+1}^{(r)} = P_{w_{k+rN+1}} D\phi^{h_{k+rN}}(w_{k+rN}) u_k^{(r)} + P_{w_{k+rN+1}} g_k, \quad k \in Z \tag{67}$$

such that for all k

$$|u_k^{(r)}| \leqslant \|L_w^{-1}\| \|\mathbf{g}\|. \tag{68}$$

Next, by Cantor's diagonalization procedure, we can find a subsequence $u_k^{(j_r)} \to \bar{u}_k$, where $\bar{u}_k$ is orthogonal to $f(y_k)$, as $r \to \infty$ for each k. Then letting $r \to \infty$ in (67) and (68) (with r replaced by j_r), we obtain

$$\bar{u}_{k+1} = P_{y_{k+1}} D\phi^{\ell_k}(y_k)\bar{u}_k + g_k, \quad k \in Z$$

and

$$|\bar{u}_k| \leqslant \|L_w^{-1}\| \|\mathbf{g}\| \tag{69}$$

for all k. In particular, since $\mathbf{g}$ is arbitrary, this means that the difference equation

$$u_{k+1} = P_{y_{k+1}} D\phi^{\ell_k}(y_k) u_k + g_k$$

has a solution u_k bounded on $[0, \infty)$, where u_k is orthogonal to $f(y_k)$, whenever g_k is a sequence bounded on $[0, \infty)$ with g_k orthogonal to $f(y_{k+1})$. It follows from the discrete analogue of Proposition 3 of Lecture 3 in [5] that the difference equation

$$u_{k+1} = P_{y_{k+1}} D\phi^{\ell_k}(y_k) u_k,$$

where u_k is orthogonal to $f(y_k)$, has an exponential dichotomy on $[0, \infty)$. However, then it follows from the discrete analogue of the periodic case of Proposition 3 in Lecture 8 of [5] that the equation has an exponential dichotomy on Z. This, in turn, means that L_y is invertible so that the equation

$$u_{k+1} = P_{y_{k+1}} D\phi^{\ell_k}(y_k) u_k + g_k, \quad k \in Z$$

has the unique bounded solution $(L_y^{-1}\mathbf{g})_k$ orthogonal to $f(y_k)$. Thus $\bar{u}_k = (L_y^{-1}\mathbf{g})_k$ and it follows from (69) that

$$\|L_y^{-1}\| \leqslant \|L_w^{-1}\|.$$

Then it follows from Lemma 7.7 applied to $\{y_k\}_{k=-\infty}^{+\infty}$ and $\{\ell_k\}_{k=-\infty}^{+\infty}$ (note that $h_{\min} \leqslant \ell_k \leqslant h_{\max}$ and that $|f(y_k)| \geqslant \Delta$) that provided $\delta < \delta_0$ there is a unique orbit $\{x_k\}_{k=-\infty}^{+\infty}$ of (53) with associated times $\{t_k\}_{k=-\infty}^{+\infty}$ such that for all k

$$f(y_k)^*(x_k - y_k) = 0, \quad |x_k - y_k| \leqslant C\delta, \quad |t_k - \ell_k| \leqslant C\delta.$$

However, since for all k

$$f(y_k)^*(x_{k+N} - y_k) = f(y_{k+N})^*(x_{k+N} - y_{k+N}) = 0,$$

and

$$|x_{k+N} - y_k| = |x_{k+N} - y_{k+N}| \leqslant C\delta, \qquad |t_{k+N} - \ell_k| = |t_{k+N} - \ell_{k+N}| \leqslant C\delta$$

also, it follows by uniqueness that $x_{k+N} = x_k$ and $t_{k+N} = t_k$ for all k. Hence $\phi^t(x_0)$ has period $t_0 + t_1 + \cdots + t_{N-1}$. Also note it follows from Lemma 7.7 that x_0 is not an equilibrium and that $\phi^t(x_0)$ is hyperbolic.

Next, by Lemma 7.7 applied to $\{w_k\}_{k=-\infty}^{+\infty}$ and $\{h_k\}_{k=-\infty}^{+\infty}$, provided $\delta < \delta_0$, there is a unique orbit $\{z_k\}_{k=-\infty}^{\infty}$ of (53) with associated times $\{s_k\}_{k=-\infty}^{+\infty}$ such that for all k

$$f(w_k)^*(z_k - w_k) = 0, \quad |z_k - w_k| \leqslant C\delta, \quad |s_k - h_k| \leqslant C\delta.$$

Again $\phi^t(z_0)$ is hyperbolic.

Next it follows from Lemma 7.8 that

$$z_k - x_k \to 0 \quad \text{and} \quad s_k - t_k \to 0 \quad \text{as } k \to \infty.$$

Now for all k

$$s_k = h_k + s_k - h_k \geqslant h_{\min} - C\delta > 0.$$

We denote by $O(x_0)$ the orbit of x_0. Then, if $0 \leqslant t \leqslant s_k$,

$$\begin{aligned} \operatorname{dist}\bigl(\phi^t(z_k), O(x_0)\bigr) &\leqslant \bigl|\phi^t(z_k) - \phi^t(x_k)\bigr| \\ &\leqslant \mathrm{e}^{M_1 t}|z_k - x_k| \\ &\leqslant \mathrm{e}^{M_1(h_{\max}+C\delta)}|z_k - x_k|. \end{aligned}$$

It follows that $\operatorname{dist}(\phi^t(z_0), O(x_0)) \to 0$ as $t \to \infty$.

Similarly, we prove that $\operatorname{dist}(\phi^t(z_0), O(x_0)) \to 0$ as $t \to -\infty$.

Finally to show that z_0 does not lie on the periodic orbit, we first note that for $0 \leqslant t \leqslant t_k$

$$\phi^t(x_k) - x_k = \int_0^t f\bigl(\phi^s(x_k)\bigr)\,\mathrm{d}s$$

so that

$$\bigl|\phi^t(x_k) - x_k\bigr| \leqslant \bigl|f(x_k)\bigr|t + \int_0^t \bigl|f\bigl(\phi^s(x_k)\bigr) - f(x_k)\bigr|\,\mathrm{d}s$$

and hence for $0 \leqslant t \leqslant t_k$

$$\left|\phi^t(x_k) - x_k\right| \leqslant \left|f(x_k)\right|t + M_1 \int_0^t \left|\phi^s(x_k) - x_k\right| \mathrm{d}s.$$

Then it follows from Gronwall's lemma that for $0 \leqslant t \leqslant t_k$

$$\left|\phi^t(x_k) - x_k\right| \leqslant \left|f(x_k)\right| \frac{\mathrm{e}^{M_1 t} - 1}{M_1}.$$

Then for $0 \leqslant t \leqslant t_k$, $k = 0, \dots, N-1$,

$$\begin{aligned}\left|z_r - \phi^t(x_k)\right| &\geqslant |w_r - y_k| - \left|\phi^t(x_k) - x_k\right| - |x_k - y_k| - |w_r - z_r| \\ &> \left(\left|f(y_k)\right| + M_1 C\delta\right) \frac{\mathrm{e}^{M_1(h_{\max} + C\delta)} - 1}{M_1} + 2C\delta \\ &\quad - \left|f(x_k)\right| \frac{\mathrm{e}^{M_1 t} - 1}{M_1} - 2C\delta \\ &\geqslant 0,\end{aligned}$$

where we have used (54). Hence z_r does not lie on the periodic orbit. So the point z_0 is indeed a transversal homoclinic point to the periodic orbit $\phi^t(x_0)$, where we note that the transversality follows from the hyperbolicity.

Thus the proof of the theorem is completed. □

EXAMPLE 7.9. In [4], Theorem 7.5 (with some refinement of the estimates) is used to show that the *Lorenz Equations*

$$\begin{aligned}\dot{x}_1 &= \sigma(x_2 - x_1), \\ \dot{x}_2 &= \rho x_1 - x_2 - x_1 x_3, \\ \dot{x}_3 &= x_1 x_2 - \alpha x_3\end{aligned}$$

with the classic parameter values

$$\sigma = 10.0, \quad \rho = 28.0, \quad \beta = 8/3$$

possess a hyperbolic periodic orbit with an associated transversal homoclinic orbit.

Abstract

In this work, we investigate the solvability and the approximate construction of solutions of certain types of regular non-linear boundary value problems for systems of ordinary differential equations on a compact interval. For this purpose, we construct analytically a uniformly convergent parametrised sequence of functions depending on the properties of the concrete boundary conditions and non-linearities in the given systems. The value of the parameter introduced artificially into the scheme is to be determined by solving a certain system of algebraic or transcendental equations.

The text is divided into 10 sections. Sections 1 and 2 contain the notation used in what follows and provide a short introduction. In Section 3, the successive approximation techniques are treated for the investigation of periodic solutions of non-autonomous periodic systems. In Section 4, we apply the method for the study the periodic solutions of autonomous systems by using the appropriate reduction to a non-autonomous system. In Section 5, we establish conditions under which a system of non-linear non-autonomous ordinary differential equations has a family of solutions that are periodic with a common period and possess a certain symmetry property. Sections 6 and 7 deal with the investigation of non-linear two-point boundary value conditions by using a parametrisation that leads one to a family of problem with linear two-point conditions considered together with certain additional algebraic or transcendental equations with respect to certain parameters. In Section 8, we use the parametrisation approach to study some three-point non-linear boundary value problem which, as a result, can be investigated through auxiliary two-point problems. Most of theoretical results are illustrated by examples. Section 9 contains some historical remarks concerning the development and application of the method. Finally, in Section 10, we give several exercises concerning the successive approximation technique under consideration.

1. Notation

(1) $\mathbb{R} = (-\infty, \infty)$, $\mathbb{R}_+ = [0, \infty)$, $\mathbb{Z} = \{0, \pm 1, \pm 2, \ldots\}$, $\mathbb{N} = \{1, 2, \ldots\}$.

(2) C_T^n is the Banach space of continuous vector-functions $x = (x_k)_{k=1}^n : (-\infty, \infty) \to \mathbb{R}^n$ periodic with period T (i.e., $x(t) = x(t+T)$ for any $t \in (-\infty, \infty)$), with the usual norm

$$x \longmapsto \max_{k=1,2,\ldots,n} \max_{t \in [0,T]} \left| x_k(t) \right|. \tag{1.1}$$

(3) $C([0, T] \times D, \mathbb{R}^n)$, where $D \subset \mathbb{R}^n$ is a compact set, stands for the Banach space of continuous vector-functions $x = (x_k)_{k=1}^n : [0, T] \to \mathbb{R}^n$ with norm (1.1).

(4) $L_1([0, T], \mathbb{R}^n)$ is the Banach space of the Lebesgue integrable functions $x = (x_k)_{k=1}^n : (-\infty, \infty) \to \mathbb{R}^n$ with the norm

$$x \longmapsto \max_{k=1,2,\ldots,n} \int_0^T \left| x_k(t) \right| \mathrm{d}t.$$

(5) $\mathrm{GL}_n(\mathbb{R})$ is the algebra of square real matrices of dimension n.

(6) $\mathbb{1}_n$ is the n-dimensional unit matrix.

(7) The symbol $r(A)$ stands for the spectral radius of a square matrix A.

(8) I is the identity operator in various spaces.

(9) $\partial\Omega$ is the boundary of a set $\Omega \subset \mathbb{R}^n$.

(10) If $\Omega_1 \subset \mathbb{R}^n$, $\Omega_2 \subset \mathbb{R}^n$, and $\{\alpha_1, \alpha_2\} \subset \mathbb{R}$, then $\alpha_1\Omega_1 + \alpha_2\Omega_2 := \{\alpha_1 x_1 + \alpha_2 x_2 \mid x_1 \in \Omega_1,\ x_2 \in \Omega_2\}$.

(11) For a point $x = \mathrm{col}(x_{1,} x_2, \ldots, x_n) \in \mathbb{R}^n$, we denote by $|x|$ the vector $|x| = \mathrm{col}(|x_1|, |x_2|, \ldots, |x_n|)$. Similarly, the signs $|\cdot|$, max, min, and $\leqslant$ for vectors are understood componentwise.

(12) Let $\beta = \mathrm{col}(\beta_1, \ldots, \beta_n)$ be a vector from $\mathbb{R}_+^n$. By the β-neighbourhood of a point $y \in \mathbb{R}^n$ we understand the set $B(y, \beta)$ of points defined as follows:

$$B(y, \beta) := \left\{ x \in \mathbb{R}^n \mid |x - y| \leqslant \beta \right\}. \tag{1.2}$$

(13) For any vector $\beta \in \mathbb{R}_+^n$, by D_β, we mean the set

$$D_\beta := \left\{ x \in D \mid B(x, \beta) \subset D \right\} \tag{1.3}$$

that consists of points $x \in \mathbb{R}^n$ lying in D together with their β-neighbourhoods.

The symbol $\square$ denotes the end of a proof.

2. Introduction

In this work, we investigate several types of regular boundary value problems for the system of ordinary differential equations

$$x'(t) = f\big(t, x(t)\big), \quad t \in [0, T], \tag{2.1}$$

where $T \in (0, +\infty)$, $f \in C([0, T] \times D, \mathbb{R}^n)$. Here, D is the closure of a connected and bounded domain in $\mathbb{R}^n$. We are interested in continuously differentiable solutions of (2.1) which satisfy either the periodic conditions

$$x(0) = x(T) \tag{2.2}$$

or certain other, more complicated kinds of two or three-point boundary conditions, both linear and non-linear ones.

The singular problems are not dealt with in this text. We refer, in particular, to the work of Agarwal and O'Regan [2] for a survey of recent results on problems for Eqs. (2.1) having singularities with respect to the independent variable.

Boundary value problems for higher order scalar equations with both time and space singularities are discussed in the work of Rachůnková, Staněk, and Tvrdý [59]. The techniques used there are based on construction of certain sequences of regular problems that are assumed to be solvable and whose solutions can be regarded as approximations of the solution in question. Certain singular two-point problems with separated boundary conditions are studied in [59] by using the method of upper and lower functions.

Singular boundary value problems for systems (2.1) in various complicated cases are studied by Kiguradze [36] by using techniques based upon properties of differential inequalities.

The solvability of various boundary value problems by using fixed point theorems is studied, in particular, by Ntouyas [52]. The works cited also contain an extensive bibliography on the subject.

In this text, we investigate systems (2.1) subjected to the boundary conditions

$$g\big(x(0), x(T)\big) = 0, \tag{2.3}$$

which are, generally speaking, non-separated and non-linear. Conditions (2.3), obviously, cover the periodic conditions (2.2), the separated non-linear conditions

$$x(0) = b\big(x(T)\big), \tag{2.4}$$

and so on. We also study the three-point problems with the conditions

$$Ax(0) + Bx(\xi) + Cx(T) = d. \tag{2.5}$$

In order to show the existence of a solution and provide an efficient algorithm for its approximate finding, we construct a certain uniformly convergent sequence of functions that depends essentially on the character of concrete non-linearities in system (2.1) and on the form of the given boundary conditions. This approach may be regarded as a generalisation of the Picard successive approximation scheme.

In the original works of Samoilenko [82,83] and Samoilenko and Ronto [88–90], the approach used and described here had been referred to as the numerical-analytic method based upon successive approximations. The idea of the method, originally aimed at the investigation of periodic solutions only, had been later applied in studies of numerous types of boundary value problems. The monograph of Farkas [17], in particular, refers to it as to a relatively new, powerful, and popular means for the investigation of periodic solutions of non-linear periodic systems of ordinary differential equations. The merit of this method is that it gives an opportunity to solve two main questions of the theory of periodic motions, namely, to establish existence theorems and to construct approximate solutions.

It should be noted that appropriate versions of the method considered can be applied in many situations for handling periodic or two-point non-linear boundary value problems in the case of systems of first or second order ordinary differential equations, integro-differential equations, equations with retarded argument and equations with more general argument deviations, systems containing unknown parameters, and countable systems of differential equations. A survey of the investigations on the subject can be found in the series of papers by Ronto, Samoilenko, and Trofimchuk [74,76,77,75,78–80] where the achievements and trends in the development of the method for the period of about 40 years are described. This text is devoted to applications of the method to the existence analysis and approximate finding of solutions of periodic and some other boundary value problems for ordinary differential equations.

In what follows, it is convenient to use the term “periodic boundary value problem” rather than “T-periodic solution of a T-periodic system of differential equations” and, instead of $\mathbb{R}$, consider the segment $[0, T]$ as the domain of definition of the equation.

The scheme of the method under consideration is rather simple. According to the basic idea of the method, the given periodic boundary value problem is replaced by the Cauchy problem for a “perturbed” differential equation containing some artificially introduced parameter, whose value is to be determined later. The solution of this family of systems of differential equations parametrised by a single vector parameter is sought for in the analytic form by the method of successive approximations. Thus, all the iterations depend upon the parameter mentioned.

As regards the way how the auxiliary problem is constructed, it is essential that the form of the “perturbation term” generates a certain system of (algebraic or transcendental) “determining equations,” which give the numerical values of the parameter corresponding to the solutions sought for. By studying these determining equations, we can establish existence results for the original problem.

Thus, the method consists of two main parts, namely, the “analytic” part, i.e., solving the auxiliary problem for the “perturbed” equation by the method of successive approximations, and then the “numerical ”part, when the determining equations are solved.

The text is organised as follows. Sections 1 and 2 contain the notation used in what follows and provide a short introduction.

In Section 3, the successive approximation techniques are treated for the investigation of periodic solutions of non-autonomous periodic systems.

In Section 4, we apply the method for the study the periodic solutions of autonomous systems by using the appropriate reduction to a non-autonomous system.

In Section 5, we establish conditions under which a system of non-linear non-autonomous ordinary differential equations has a family of solutions that are periodic with a common period and possess a certain generalised symmetry property.

Sections 6 and 7 deal with the investigation of non-linear boundary problems by using a parametrisation that leads one to a family of problems with linear two-point conditions considered together with certain additional algebraic or transcendent equations.

In Section 8, we use the parametrisation approach to study some three-point boundary value problems, which, as a result, can be investigated through auxiliary two-point problems.

Section 9 contains some historical remarks concerning the development and application of the method.

In Section 10, we pose several problems concerning the method of successive approximations.

3. Periodic successive approximations for non-autonomous systems

Let us consider the system of ordinary differential equations

$$x'(t) = f\big(t, x(t)\big), \quad t \in (-\infty, \infty), \tag{3.1}$$

where the right-hand side function f is such that $f \in C([0,T] \times D, \mathbb{R}^n)$ and

$$f(t,x) = f(t+T, x) \tag{3.2}$$

for all $x \in D$ and all real t. Here, T is a positive number and D is the closure of a bounded and connected domain in $\mathbb{R}^n$.

We are interested in continuously differentiable solutions of system (3.1) which are periodic with period T (i.e., belonging to C_T^n). It follows from Lemma 3.1 below that this problem is equivalent to finding a solution of the periodic boundary value problem (2.1), (2.2) on the bounded interval $[0,T]$:

$$x'(t) = f\big(t, x(t)\big), \quad t \in [0,T], \tag{3.3}$$

$$x(0) = x(T). \tag{3.4}$$

LEMMA 3.1. (See, e.g., [17, Lemma 2.2.1].) *If a function* $x : (-\infty, \infty) \to D$ *is a* T*-periodic solution of system* (3.1)*, then its restriction* $x|_{[0,T]}$ *to* $[0,T]$ *satisfies system* (3.3), (3.4). *Conversely, if* x: $[0,T] \to D$ *is a solution of the boundary value problem* (3.3), (3.4)*, then its continuous* T*-periodic extension to* $(-\infty, \infty)$ *is a* T*-periodic solution of system* (3.1).

The solution of the periodic boundary value problem (3.3), (3.4) can be considered as a restriction of the T-periodic solution of the T-periodic system (3.1) onto the segment $[0,T]$. Thus, below we consider the segment $[0,T]$ instead of $\mathbb{R}$ in the domain of definition (3.2): $f \in C([0,T] \times D, \mathbb{R}^n)$.

It is assumed that the following conditions hold for the periodic boundary value problem (3.3), (3.4):

(1) For any $t \in [0, T]$ fixed, the function $f(t, \cdot)$ for all $\{x_1, x_2\} \subset D$ satisfies the Lipschitz condition

$$\bigl|f(t, x_1) - f(t, x_2)\bigr| \leqslant K|x_1 - x_2| \tag{3.5}$$

with some non-negative matrix $K = \{K_{ij}\}_{i,j=1}^{n} \in \mathrm{GL}_n(\mathbb{R})$ and, furthermore, the estimate

$$\frac{1}{2}\Bigl[\max_{(t,x)\in[0,T]\times D} f(t, x) - \min_{(t,x)\in[0,T]\times D} f(t, x)\Bigr] \leqslant M \tag{3.6}$$

is true with some $M \in \mathbb{R}_{+}^{n}$.

(2) The maximal eigenvalue $r(K)$ of the matrix K in (3.5) is such that

$$r(K) < \frac{10}{3T}. \tag{3.7}$$

(3) The set $D_{\frac{T}{2}M}$ is non-empty:

$$D_{\frac{T}{2}M} \neq \varnothing \tag{3.8}$$

Recall that the set $D_{\frac{T}{2}M}$ is defined according to notation (13), Section 1. It is clear that the form of this set essentially depends on the properties of the function f and the structure of the domain D.

REMARK 3.2. Inequality (3.7) is equivalent to the condition that the greatest eigenvalue of the matrix

$$Q = \frac{T}{q}K, \tag{3.9}$$

where

$$q = \frac{10}{3}, \tag{3.10}$$

is less than 1.

REMARK 3.3. By virtue of the non-negativity of K, it follows from the Perron theorem (see, e.g., Krein and Rutman [38]) that the largest eigenvalue of this matrix is real, non-negative, and is estimated from above by the number

$$\min\Biggl\{\max_{i=1,\dots,n}\sum_{j=1}^{n} K_{ij}, \max_{j=1,\dots,n}\sum_{i=1}^{n} K_{ij}\Biggr\}.$$

In (1.2), as well as in (3.6), (3.5) and similar relations below, the signs $|\cdot|$, max, min, and $\leqslant$ are understood componentwise. Note that the componentwise estimate of form (3.5), (3.6), etc., in general, are more accurate than the corresponding estimates in terms of the norm because they use the algebraic structure of the space $\mathbb{R}^n$ in a more subtle way.

REMARK 3.4. One can verify (see Remark 2 in Rontó and Mészáros [69]) that the inequality

$$\frac{1}{2}\Big[\max_{(t,x)\in[0,T]\times D} f(t,x) - \min_{(t,x)\in[0,T]\times D} f(t,x)\Big] \leqslant \max_{(t,x)\in[0,T]\times D}\big|f(t,x)\big|, \tag{3.11}$$

is true. Moreover, the equality

$$\frac{1}{2}\Big[\max_{(t,x)\in[0,T]\times D} f(t,x) - \min_{(t,x)\in[0,T]\times D} f(t,x)\Big] = \max_{(t,x)\in[0,T]\times D}\big|f(t,x)\big|$$

holds if, and only if

$$\max_{(t,x)\in[0,T]\times D} f(t,x) = -\min_{(t,x)\in[0,T]\times D} f(t,x) = \max_{(t,x)\in[0,T]\times D}\big|f(t,x)\big|.$$

EXAMPLE 3.5. For the function

$$f(t,x) = \frac{1}{2}\ln x \sin t + 12$$

defined for (t,x) from the domain $[0,T]\times D = [0,2\pi]\times[\mathrm{e},\mathrm{e}^2] =: G$, estimate (3.6) is sharper than the inequality $|f(t,x)| \leqslant M$. Indeed, it easy to see that

$$\max_{(t,x)\in[0,T]\times D}\big|f(t,x)\big| = 13$$

and

$$\frac{1}{2}\Big[\max_{(t,x)\in[0,T]\times D} f(t,x) - \min_{(t,x)\in[0,T]\times D} f(t,x)\Big] = \frac{1}{2}[13-11] = 1.$$

Taking into account that the vector M and the matrix K in estimates (3.6), (3.5) depend on the domain D, it may happen that conditions (3.6)–(3.8) for system (3.1) are satisfied in some domain D (or some subdomains of D) and does not hold in another one. Let us consider some examples to illustrate this fact.

EXAMPLE 3.6. Assume that the function f in (3.1) satisfies conditions (3.6), (3.5) for $(t,x)\in\mathbb{R}\times\mathbb{R}^n$.

If inequality (3.7) is satisfied with some Lipschitz matrix K, then condition (3.8) also holds in any closed bounded domain D containing an n-dimensional rectangle with the side length componentwise greater than $\frac{T}{2}M$.

EXAMPLE 3.7. Consider the case where (3.1) is a linear system,

$$x'(t) = P(t)x + q(t), \tag{3.12}$$

where $q \in C_T^n$ and $P = \{P_{ij}\}_{i,j=1}^n$, P_{ij}, $i, j = 1, 2, \dots, n$, are continuous T-periodic functions.

Let us put $\hat{P} := \{\max_{t\in[0,T]} |P_{ij}(t)|\}_{i,j=1}^n$,

$$\hat{q} := \operatorname{col}\Big(\max_{t\in[0,T]}\big|q_1(t)\big|, \dots, \max_{t\in[0,T]}\big|q_n(t)\big|\Big)$$

and consider system (3.12) in the domain

$$D := \big\{x \mid |x| \leqslant b\big\}, \tag{3.13}$$

where $b = \operatorname{col}(b_1, \dots, b_n)$ is such that conditions (3.6)–(3.8) hold for system (3.12).

We can put $K = \hat{P}$ in (3.5). According to (3.11), condition (3.6) takes the form

$$\big|f(t, x)\big| \leqslant \big|P(t)x + q(t)\big| \leqslant \hat{P}b + \hat{q} =: M.$$

Condition (3.8) holds in domain (3.13) if the inequality

$$\hat{q} \leqslant \frac{2}{T}\left(\mathbb{1}_n - \frac{T}{2}\hat{P}\right)b.$$

is true. In particular, when $r(\hat{P}) < 2T^{-1}$, we can put

$$b = \frac{T}{2}\left(\mathbb{1}_n - \frac{T}{2}\hat{P}\right)\hat{q}.$$

Condition (3.7) holds whenever the greatest eigenvalue of the matrix $\hat{P}$ does not exceed $\frac{10}{3T}$.

EXAMPLE 3.8. Let us consider the system of equations

$$\begin{aligned} x_1'(t) &= x_2(t), \\ x_2'(t) &= -x_1(t) - \sin(20t)\big(x_2(t)\big)^s + \cos(20t) \end{aligned} \tag{3.14}$$

for $(t, x) \in [0, \frac{\pi}{10}] \times D$, where

$$D := \big\{(x_1, x_2) \mid |x_1| \leqslant a, |x_2| \leqslant 1\big\}. \tag{3.15}$$

Then, for $s \geqslant 0$, the function

$$f(t, x_1, x_2) := \begin{pmatrix} x_2 \\ -x_1 - (\sin 20t)x_2^s + \cos(20t) \end{pmatrix} \tag{3.16}$$

defined on the set $[0, T] \times D$ with $T = \frac{\pi}{10}$ satisfies the relation

$$\bigl|f(t,x)\bigr| \leqslant \operatorname{col}(1, a+2) =: M$$

for all $(t, x) \in [0, \frac{\pi}{10}] \times D$. Furthermore, the Lipschitz condition (3.5) holds with $K = \left[\begin{smallmatrix} 0 & 1 \\ 1 & s \end{smallmatrix}\right]$. The set (3.8) corresponding to system (3.14) is defined as follows:

$$D_{\frac{\pi}{20}M} = \left\{ (x_1, x_2) \;\middle|\; |x_1| \leqslant a - \frac{\pi}{20},\ |x_2| \leqslant 1 - \frac{\pi}{20}(a+2) \right\}.$$

This subdomain is non-empty if

$$a - \frac{\pi}{20} \geqslant 0,$$
$$1 - \frac{\pi}{20}(a+2) \geqslant 0,$$

whence we see that $D_{\frac{\pi}{20}M} \neq \varnothing$ whenever a satisfies the relations

$$\frac{\pi}{20} \leqslant a \leqslant \frac{20}{\pi} - 2. \tag{3.17}$$

It is easy to see that λ is an eigenvalue of the matrix K if, and only if $\lambda^2 - \lambda s - 1 = 0$, whence

$$r(K) = \frac{s + \sqrt{s^2+4}}{2}.$$

Therefore, condition (3.7) holds whenever $\frac{3\pi}{100}\frac{s+\sqrt{s^2+4}}{2} < 1$, $\sqrt{s^2+4} < \frac{200}{3\pi} - s$, or, finally, when

$$s < \frac{100}{3\pi} - \frac{3\pi}{100}. \tag{3.18}$$

Thus, the conditions (3.6)–(3.8) for the system (3.14) are fulfilled in the domain (3.15) if the values a and s satisfy the inequalities (3.17), (3.18).

EXAMPLE 3.9. Let us consider the damped Duffing equation with periodic forcing term (see (3.3.8) and (4.3.15) in [17])

$$x''(t) + dx' + ax(t) + b\bigl(x(t)\bigr)^3 = H \sin\left(\frac{2\pi}{T}t\right), \tag{3.19}$$

where $a > 0$, $d > 0$, $b \in \mathbb{R}$ (“soft” or “hard spring”), $H \in \mathbb{R}$. Equation (3.19) is equivalent to the Cauchy normal form system

$$\begin{aligned} x_1'(t) &= x_2(t), \\ x_2'(t) &= -dx_2(t) - ax_1(t) - bx_1^3(t) + H\sin\left(\frac{2\pi}{T}t\right). \end{aligned} \tag{3.20}$$

For the domain of definition of this system, we take

$$(t, x) \in [0, T] \times D, \quad D := \bigl\{(x_1, x_2)\colon |x_1| \leqslant m, |x_2| \leqslant 1\bigr\}. \tag{3.21}$$

In this case, the right-hand side function, f, in (3.20) satisfies the relation

$$\bigl|f(t, x)\bigr| \leqslant \operatorname{col}\bigl(1, d + am + |b|m^3 + |H|\bigr) =: M$$

and the Lipschitz condition (3.5) with

$$K = \begin{bmatrix} 0 & 1 \\ a + 3|b|m & d \end{bmatrix}.$$

The set (3.8) for system (3.20) is determined by the formula

$$D_{\frac{T}{2}M} = \left\{(x_1, x_2) \mid |x_1| \leqslant m - \frac{T}{2}, |x_2| \leqslant 1 - \frac{T}{2}\bigl(d + am + |b|m^3 + |H|\bigr)\right\}.$$

This subdomain is non-empty if

$$\begin{aligned} &m - \frac{T}{2} \geqslant 0, \\ &1 - \frac{T}{2}\bigl(d + am + b|m^3 + |H|\bigr) \geqslant 0. \end{aligned}$$

Thus, condition (3.8) holds whenever

$$m \geqslant \frac{T}{2}, \qquad am + |b|m^3 \leqslant \frac{2}{T} - d. \tag{3.22}$$

Since the eigenvalues λ of the matrix K are determined by the equation

$$\lambda^2 - d\lambda - \bigl(a + 3|b|m^2\bigr) = 0,$$

it is obvious that

$$r(K) = \frac{d + \sqrt{d^2 + 4(a + 3|b|m^2)}}{2}$$

and, therefore, (3.21) holds if

$$d + \sqrt{d^2 + 4\big(a + 3|b|m^2\big)} < \frac{20}{3T}. \tag{3.23}$$

Conditions (3.6)–(3.8) for system (3.20) are satisfied in domain (3.21) when the values of the parameters a, b, d, H, and m satisfy inequalities (3.22), (3.23).

We can now return to the investigation of T-periodic solution of system (3.1), which, as we have mentioned above, is equivalent to the periodic boundary value problem (3.3), (3.4).

Let us put

$$(Lx)(t) := \int_0^t x(s)\,\mathrm{d}s - \frac{t}{T}\int_0^T x(s)\,\mathrm{d}s, \quad t \in [0, T]. \tag{3.24}$$

Obviously, formula (3.24) determines a continuous linear operator in the space $C([0, T], \mathbb{R}^n)$. Moreover, one can easily verify that the following lemma holds.

LEMMA 3.10. *For an arbitrary x from $C([0, T], \mathbb{R}^n)$,*

$$(Lx)(0) = (Lx)(T).$$

Consider the parametrised integral equation

$$x(t) = z + \int_0^t \left(f\big(s, x(s)\big) - \frac{1}{T}\int_0^T f\big(\tau, x(\tau)\big)\,\mathrm{d}\tau \right) \mathrm{d}s$$

or, which is the same,

$$x(\cdot) = z + Lf\big(\cdot, x(\cdot)\big) \tag{3.25}$$

where $z \in \mathbb{R}^n$ is a vector parameter.

REMARK 3.11. It is clear from Lemma 3.10 that every solution x of Eq. (3.25) satisfies the T-periodic boundary condition (3.4); see also the discussion of Eq. (4.1.19) in [17, Section 4.1].

We have the following simple

PROPOSITION 3.12. *If $x(\cdot, z)$ is a solution of the integro-differential equation*

$$x'(t) = f\big(t, x(t)\big) - \frac{1}{T}\int_0^T f\big(s, x(s)\big)\,\mathrm{d}s, \quad t \in [0, T], \tag{3.26}$$

with the initial value condition

$$x(0) = z \tag{3.27}$$

and, moreover,

$$\int_0^T f\bigl(s, x(s,z)\bigr)\,\mathrm{d}s = 0, \tag{3.28}$$

then $x(\cdot, z)$ is also a solution of the T-periodic boundary value problem (3.3), (3.4).

Conversely, if a function x satisfies (3.3), (3.4), *then it is also a solution of the initial value problem* (3.26), (3.27) *with $z = x(0)$.*

PROOF. It is obvious that a continuously differentiable function x satisfying the initial value problem (3.26), (3.27) is a continuous solution of Eq. (3.25) and *vice versa*. Therefore, by virtue of Remark 3.11, a solution x of (3.26), (3.27) satisfies the T-periodic boundary condition (3.4) for an arbitrary z. Thus, it follows that (3.26), (3.27), and (3.28) imply (3.3), (3.4).

Conversely, if x is a solution of the T-periodic problem (3.3), (3.4), then

$$\int_0^T f\bigl(s, x(s)\bigr)\,\mathrm{d}s = 0$$

and, hence, (3.26), (3.27) hold with $z = x(0)$. □

Equation (3.26) can be considered as a perturbed version of Eq. (3.1) with the perturbation term determined by the expression in the left-hand side of (3.28).

We shall show that, under conditions (3.6)–(3.8), the integral equation (3.25) can be solved by the method of successive approximations. This is the "analytic" part of our method.

With the integral equation (3.25), we associate the following sequence of T-periodic functions $\{x_m(\cdot, z)\}_{m=0}^{+\infty}$ depending on the parameter $z \in \mathbb{R}^n$:

$$x_m(t,z) = z + \int_0^t \left[f\bigl(s, x_{m-1}(s,z)\bigr) - \frac{1}{T}\int_0^T f\bigl(\tau, x_{m-1}(\tau,z)\bigr)\,\mathrm{d}\tau \right] \mathrm{d}s, \tag{3.29}$$

where $m = 1, 2, \ldots$ and $x_0(t,z) = z$.

It is obvious from Lemma 3.10 that

$$x_m(0,z) = x_m(T,z), \qquad x_m(0,z) = z$$

for every natural m.

Let us establish two subsidiary statements needed below for the convergence analysis of sequence (3.29).

LEMMA 3.13. *Let* $f:[0,T]\to\mathbb{R}^n$ *be a continuous function. Then, for an arbitrary* $t\in[0,T]$, *the inequality*

$$\left|(Lf)(t)\right| \leqslant \frac{1}{2}\alpha_{1,T}(t)\Big[\max_{t\in[0,T]} f(t) - \min_{t\in[0,T]} f(t)\Big], \tag{3.30}$$

holds, where the operator L *is given by formula* (3.24) *and*

$$\alpha_{1,T}(t) := 2t\left(1-\frac{t}{T}\right), \quad t\in[0,T]. \tag{3.31}$$

REMARK 3.14. It is easy to see that the estimate

$$0 \leqslant \alpha_{1,T}(t) \leqslant \frac{T}{2}, \quad t\in[0,T] \tag{3.32}$$

holds for function (3.31).

PROOF OF LEMMA 3.13. It is obvious that

$$\begin{aligned}
&\int_0^t \left[f(\tau) - \frac{1}{T}\int_0^T f(s)\,\mathrm{d}s\right]\mathrm{d}\tau \\
&\quad = \frac{1}{T}\int_0^t\int_0^T \big[f(\tau)-f(s)\big]\,\mathrm{d}s\,\mathrm{d}\tau \\
&\quad = \frac{1}{T}\int_0^t\int_0^t \big[f(\tau)-f(s)\big]\,\mathrm{d}s\,\mathrm{d}\tau + \frac{1}{T}\int_0^t\int_t^T \big[f(\tau)-f(s)\big]\,\mathrm{d}s\,\mathrm{d}\tau.
\end{aligned}$$

Furthermore,

$$\begin{aligned}
\int_0^t\int_0^t \big[f(\tau)-f(s)\big]\,\mathrm{d}s\,\mathrm{d}\tau &= \int_0^t \left[t f(\tau) - \int_0^t f(s)\,\mathrm{d}s\right]\mathrm{d}\tau \\
&= t\int_0^t f(\tau)\,\mathrm{d}\tau - t\int_0^t f(s)\,\mathrm{d}s = 0.
\end{aligned}$$

Therefore,

$$\begin{aligned}
\left|\int_0^t \left[f(\tau) - \frac{1}{T}\int_0^T f(s)\,\mathrm{d}s\right]\mathrm{d}\tau\right| &\leqslant \frac{1}{T}\int_0^t\int_t^T \big|f(\tau)-f(s)\big|\,\mathrm{d}s\,\mathrm{d}\tau \\
&\leqslant \frac{1}{T}\max_{\substack{\tau\in[0,t]\\ s\in[t,T]}} \big|f(\tau)-f(s)\big| t(T-t)
\end{aligned}$$

$$= \frac{1}{2}\alpha_{1,T}(t) \max_{\substack{\tau\in[0,t]\\ s\in[t,T]}} \left|f(\tau) - f(s)\right|$$

$$\leqslant \frac{1}{2}\alpha_{1,T}(t)\Big[\max_{t\in[0,T]} f(t) - \min_{t\in[0,T]} f(t)\Big].$$

The last estimate leads us to the required inequality (3.30). □

REMARK 3.15. Estimate (3.30) from Lemma 3.13 improves the corresponding estimate

$$\left|\int_0^t \left[f(\tau) - \frac{1}{T}\int_0^T f(s)\,\mathrm{d}s\right]\mathrm{d}\tau\right| \leqslant \alpha_{1,T}(t) \max_{t\in[0,T]}\left|f(t)\right| \tag{3.33}$$

of [70, Lemma 2.1].

Indeed, let us consider the function f from Example 3.5. Taking into account the fact that

$$\max_{(t,x)\in[0,T]\times D}\left|f(t,x)\right| = \max_{(t,x)\in[0,2\pi]\times[e,e^2]}\left|\frac{1}{2}\ln x\sin t + 12\right| = 13,$$

according to (3.33) and estimate (3.32) from Remark 3.14, we have

$$\left|\int_0^t \left[f(\tau,x) - \frac{1}{T}\int_0^T f(s,x)\,\mathrm{d}s\right]\mathrm{d}\tau\right| \leqslant \alpha_{1,T}(t)\cdot 13 \leqslant 13\pi \approx 40.82.$$

In view of estimate (3.30),

$$\left|\int_0^t \left[f(\tau,x) - \frac{1}{T}\int_0^T f(s,x)\,\mathrm{d}s\right]\mathrm{d}\tau\right| \leqslant \frac{\pi}{2}\cdot 1 \approx 1.57.$$

On the other hand, by direct computation, we obtain that

$$\begin{aligned}
&\int_0^t \left[\left(\frac{1}{2}\ln x\sin\tau + 12\right) - \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{1}{2}\ln x\sin s + 12\right)\mathrm{d}s\right]\mathrm{d}\tau\\
&\quad = \int_0^t \left[\left(\frac{1}{2}\ln x\sin\tau + 12\right) - \frac{1}{2\pi}24\pi\right]\mathrm{d}\tau\\
&\quad = \int_0^t \frac{1}{2}\ln x\sin\tau\,\mathrm{d}\tau = \frac{1}{2}\ln x(1-\cos t)
\end{aligned}$$

and

$$\max_{(t,x)\in[0,2\pi]\times[e,e^2]}\left|\frac{1}{2}\ln x(1-\cos t)\right| = 1.$$

LEMMA 3.16. *Let the sequence of continuous functions*

$$\alpha_{0,T}(t) = 1, \quad \alpha_{1,T}(t) = 2t\left(1 - \frac{t}{T}\right), \quad \ldots, \quad \alpha_{m,T}(t), \ldots \tag{3.34}$$

be defined by the recurrence relation

$$\begin{aligned}\alpha_{m+1,T}(t) = {} & \left(1 - \frac{t}{T}\right)\int_0^t \alpha_{m,T}(s)\,\mathrm{d}s \\ & + \frac{t}{T}\int_t^T \alpha_{m,T}(s)\,\mathrm{d}s, \quad m = 0, 1, 2, \ldots.\end{aligned} \tag{3.35}$$

Then, for all $m = 0, 1, 2, \ldots$, *the estimate*

$$\alpha_{m+1,T}(t) \leqslant \left(\frac{3T}{10}\right)^m \bar{\alpha}_{1,T}(t), \quad t \in [0, T] \tag{3.36}$$

holds, where

$$\bar{\alpha}_{1,T}(t) := \frac{10}{9}\alpha_{1,T}(t). \tag{3.37}$$

PROOF. By direct computation, from the iterative formula (3.35) we obtain

$$\alpha_{2,T}(t) = \alpha_{1,T}(t)\left[\frac{T}{6} + \frac{1}{3}\alpha_{1,T}(t)\right]$$

and

$$\alpha_{3,T}(t) = \alpha_{1,T}(t)\left[\frac{T^2}{20} + \frac{T}{15}\alpha_{1,T}(t) + \frac{1}{15}\alpha_{1,T}^2(t)\right]. \tag{3.38}$$

Taking estimate (3.32) into account, we get

$$\alpha_{2,T}(t) \leqslant \frac{T}{3}\alpha_{1,T}(t) = \frac{3}{10}T\left(\frac{10}{9}\alpha_{1,T}(t)\right) = \left(\frac{3}{10}T\right)\bar{\alpha}_{1,T}(t).$$

It follows from (3.38) that

$$\begin{aligned}\alpha_{3,T}(t) &= \frac{3}{10}T\alpha_{1,T}(t)\left[\frac{T}{6} + \frac{1}{3}\alpha_{1,T}(t)\right] - \frac{1}{30}T\alpha_{1,T}^2(t) + \frac{1}{15}\alpha_{1,T}^3(t) \\ &= \left(\frac{3}{10}T\right)\alpha_{2,T}(t) - \frac{1}{30}\alpha_{1,T}^2(t)\left[T - 2\alpha_{1,T}(t)\right] \\ &\leqslant \left(\frac{3}{10}T\right)\alpha_{2,T}(t) \leqslant \left(\frac{3}{10}T\right)^2\bar{\alpha}_{1,T}(t).\end{aligned}$$

By induction, the last inequality yields

$$\begin{aligned}\alpha_{m+1,T}(t) &\leqslant \left(1-\frac{t}{T}\right)\int_0^t \left(\frac{3}{10}T\right)\alpha_{m-1,T}(s)\,\mathrm{d}s \\ &\quad + \frac{t}{T}\int_t^T \left(\frac{3}{10}T\right)\alpha_{m-1,T}(s)\,\mathrm{d}s \\ &\leqslant \left(\frac{3}{10}T\right)\alpha_{m,T}(t) \leqslant \left(\frac{3}{10}T\right)^m \bar{\alpha}_{1,T}(t).\end{aligned}$$

Thus, we have obtained the required estimate (3.36). □

The last lemma allows us to establish a statement on the convergence of sequence (3.29).

THEOREM 3.17. *Let the T-periodic boundary-value problem* (3.3), (3.4) *be such that conditions* (3.5), (3.6), *and* (3.8) *are satisfied. Then, for an arbitrary value of the parameter $z \in D_\beta$, the following assertions are true*:

(i) *The sequence $\{x_m(\cdot, z)\}_{m\geqslant 0}$ of the T-periodic functions* (3.29) *converges uniformly in (t, z) from*

$$[0, T] \times D_{\frac{T}{2}M}; \tag{3.39}$$

(ii) *The limit function*

$$x^*(t, z) := \lim_{m\to\infty} x_m(t, z) \tag{3.40}$$

of sequence (3.29) *is the unique T-periodic solution of the integral equation* (3.25)

$$x^*(t, z) = z + \int_0^t f\bigl(s, x^*(s, z)\bigr)\,\mathrm{d}s - \frac{t}{T}\int_0^T f\bigl(s, x^*(s, z)\bigr)\,\mathrm{d}s \tag{3.41}$$

in the domain D or, which is the same, it is the unique T-periodic solution of the integro-differential equation (3.26)

$$\frac{\partial x(t, z)}{\partial t} = f\bigl(t, x(t, z)\bigr) - \Delta(z), \quad t \in [0, T], \tag{3.42}$$

where the "perturbation term" has the form

$$\Delta(z) := \frac{1}{T}\int_0^T f\bigl(t, x^*(t, z)\bigr)\,\mathrm{d}t; \tag{3.43}$$

(iii) *The estimate*

$$\bigl|x^*(t, z) - x_m(t, z)\bigr| \leqslant \bar{\alpha}_{1,T}(t) Q^m (I - Q)^{-1} M, \tag{3.44}$$

holds for all $m = 1, 2, \dots$ *and* $t \in [0, T]$, *where the function* $\bar{\alpha}_{1,T}$ *is given by* (3.37),

$$Q = \frac{3T}{10} K, \tag{3.45}$$

and K *is the matrix from the Lipschitz condition* (3.5).

REMARK 3.18. It is obvious from (3.37) and Remark 3.14 that

$$\bar{\alpha}_{1,T}(t) \leqslant \frac{5}{9} T, \quad t \in [0, T]. \tag{3.46}$$

PROOF OF THEOREM 3.17. We shall show that $\{x_m(\cdot, z)\}_{m \geqslant 0}$ given by (3.29) is a Cauchy sequence in the space $C([0, T], \mathbb{R}^n)$ and, therefore, this sequence is uniformly convergent in domain (3.39).

First we prove that if z belongs to the set $D_{\frac{T}{2}M} \subset D$, then $x_m(\cdot, z) \in D$ for all t and m. Indeed, by virtue of estimate (3.30) of Lemma 3.13 and relation (3.6), equality (3.29) implies

$$\begin{aligned}
\left|x_1(t, z) - z\right| &= \left|x_1(t, z) - x_0(t, z)\right| \\
&\leqslant \left| \int_0^t \left[f(s, z)\,\mathrm{d}s - \frac{1}{T} \int_0^T f(\tau, z)\,\mathrm{d}\tau \right] \mathrm{d}s \right| \mathrm{d}s \\
&\leqslant \frac{1}{2} \alpha_{1,T}(t) \Big[\max_{(t,z) \in [0,T] \times D_{\frac{T}{2}M}} f(t, z) - \min_{(t,x) \in [0,T] \times D_{\frac{T}{2}M}} f(t, z) \Big] \\
&\leqslant \alpha_{1,T}(t) M \leqslant \frac{T}{2} M,
\end{aligned} \tag{3.47}$$

where $\alpha_{1,T}$ is given by (3.31). Therefore, $x_1(t, z) \in D$ for $t \in [0, T]$ and $z \in D_{\frac{T}{2}M}$. Arguing by induction, one can show that

$$\left|x_m(t, z) - z\right| \leqslant \frac{T}{2} M, \tag{3.48}$$

i.e., the values of all the members $x_m(\cdot, z)$ of sequence (3.29) are contained in the domain D for all $t \in [0, T]$ and arbitrary $z \in D_{\frac{T}{2}M}$.

Let us estimate the differences between neighbouring members of sequence (3.29). We have

$$\begin{aligned}
x_{m+1}(t, z) - x_m(t, z) = \int_0^t \Big[&\big(f\big(s, x_m(s, z)\big) - f\big(s, x_{m-1}(s, z)\big)\big) \\
&- \frac{1}{T} \int_0^T \big(f\big(\tau, x_m(\tau, z)\big) - f\big(s, x_{m-1}(\tau, z)\big)\big)\,\mathrm{d}\tau \Big]\,\mathrm{d}s
\end{aligned}$$

$$
\begin{aligned}
&= \int_0^t \big[f\big(s, x_m(s,z)\big) - f\big(s, x_{m-1}(s,z)\big)\big]\,\mathrm{d}s \\
&\quad - \frac{t}{T}\int_0^T \big[f\big(s, x_m(s,z)\big) - f\big(s, x_{m-1}(s,z)\big)\big]\,\mathrm{d}s \\
&= \left(1-\frac{t}{T}\right)\int_0^t \big[f\big(s, x_m(s,z)\big) - f\big(s, x_{m-1}(s,z)\big)\big]\,\mathrm{d}s \\
&\quad - \frac{t}{T}\int_t^T \big[f\big(s, x_m(s,z)\big) - f\big(s, x_{m-1}(s,z)\big)\big]\,\mathrm{d}s. \qquad (3.49)
\end{aligned}
$$

Putting

$$r_m(t,z) := \big|x_{m+1}(t,z) - x_m(t,z)\big|, \quad t \in [0,T],$$

and taking the Lipschitz condition (3.5) into account, we see that (3.49) yields

$$r_{m+1}(t,z) \leqslant K\left[\left(1-\frac{t}{T}\right)\int_0^t r_m(s,z)\,\mathrm{d}s + \frac{t}{T}\int_t^T r_m(s,z)\,\mathrm{d}s\right]. \tag{3.50}$$

According to (3.47), we have

$$r_1(t,z) \leqslant \alpha_{1,T}(t)M \leqslant \frac{T}{2}M.$$

Therefore, for $m=1$, on base of the recurrence formula (3.35), relation (3.50) implies

$$
\begin{aligned}
r_2(t,z) &\leqslant K\left[\left(1-\frac{t}{T}\right)\int_0^t r_1(s,z)\,\mathrm{d}s + \frac{t}{T}\int_t^T r_1(s,z)\,\mathrm{d}s\right] \\
&\leqslant KM\left[\left(1-\frac{t}{T}\right)\int_0^t \alpha_{1,T}(s)\,\mathrm{d}s + \frac{t}{T}\int_t^T \alpha_{1,T}(s)\,\mathrm{d}s\right] \\
&\leqslant KM\alpha_{2,T}(t).
\end{aligned}
$$

Arguing by induction, we easily obtain

$$r_{m+1}(t,z) \leqslant K^m M\alpha_{m+1,T}(t), \quad m = 0, 1\ldots,$$

where $\alpha_{m+1,T}(t)$ is given by formula (3.33). By virtue of estimate (3.36) from Lemma 3.16, we have

$$r_{m+1}(t,z) \leqslant \bar{\alpha}_{1,T}(t)K^m\left(\frac{3T}{10}\right)^m M = \bar{\alpha}_{1,T}(t)Q^m M \tag{3.51}$$

for all $m = 1, 2\ldots$, where Q is the matrix given by (3.45).

Furthermore, in view of (3.51), the relation

$$\begin{aligned} x_{m+j}(t,z) - x_m(t,z) = {} & \big(x_{m+j}(t,z) - x_{m+j-1}(t,z)\big) \\ & + \big(x_{m+j}(t,z) - x_{m+j-2}(t,z)\big) \\ & + \cdots + \big(x_{m+1}(t,z) - x_m(t,z)\big) \end{aligned}$$

yields

$$\begin{aligned} \big|x_{m+j}(t,z) - x_m(t,z)\big| & \leqslant \sum_{i=1}^{j} r_{m+i} \leqslant \bar{\alpha}_{1,T}(t) \sum_{i=1}^{j} Q^{m+i-1} M \\ & \leqslant \bar{\alpha}_{1,T}(t) \sum_{i=0}^{j-1} Q^{m+i-1} M = \bar{\alpha}_{1,T}(t) Q^m \sum_{i=0}^{j-1} Q^i M. \end{aligned} \tag{3.52}$$

Taking into account the fact that, according to assumption (3.7), the maximal eigenvalue of matrix (3.45) is less than 1, we see that

$$\sum_{i=0}^{j-1} Q^{m+i} \leqslant \sum_{i=0}^{\infty} Q^{m+i} = Q^m (I - Q)^{-1} \tag{3.53}$$

and

$$\lim_{m \to \infty} Q^m = 0. \tag{3.54}$$

Consequently, it follows from (3.52), (3.53), and (3.54) that, for an arbitrary $t \in [0, T]$,

$$\big|x_{m+j}(t,z) - x_m(t,z)\big| \leqslant \bar{\alpha}_{1,T}(t) Q^m (I - Q)^{-1} M. \tag{3.55}$$

Inequality (3.29) implies immediately that (3.29) is a Cauchy sequence in the space $C([0,T], \mathbb{R}^n)$ and, therefore, it uniformly converges to a continuous limit function $x^*(\cdot, z)$, i.e., (3.40) holds.

Since all the functions $x_m(\cdot, z)$ of the sequence (3.29) are T-periodic, it follows its uniform limit $x^*(\cdot, z)$ is also a T-periodic function. Passing to the limit as $m \to +\infty$ in equality (3.29), we conclude that the limit function $x^*(\cdot, z)$ is indeed a unique T-periodic solution of the integral equation (3.25) with the initial value

$$x^*(0, z) = z. \tag{3.56}$$

Thus, equalities (3.41), (3.42) hold. When $j \to +\infty$ and $m = 1, 2, \ldots$, relation (3.55) yields the required estimate (3.43) for the difference between the exact solution $x^*(\cdot, z)$ of Eq. (3.41) and its mth approximation $x_m(\cdot, z)$. □

Equality (3.56) shows that, in fact, every point z from the subset $D_{\frac{T}{2}M}$ is the initial value of the unique T-periodic solution of Eqs. (3.25) and (3.26).

3.1. *Properties of the limit function*

Along with system (3.1), we shall also consider the system of equations

$$x'(t) = f\bigl(t, x(t)\bigr) - \mu, \quad t \in [0, T], \tag{3.57}$$

where $\mu = \operatorname{col}(\mu_1, \ldots, \mu_n)$ is a control parameter. Let us show that the parameter μ can always be chosen so that the solution of Eq. (3.57) having the initial value (3.27) with

$$z \in D_{\frac{T}{2}M} \tag{3.58}$$

also satisfies the T-periodic boundary condition (3.4).

In other words, this means that we can always introduce an additive perturbation of the right-hand side of the T-periodic system (3.1) such that, for an arbitrary $z \in D_{\frac{T}{2}M}$, the solution $x = x(t, 0, z, \mu)$ of the resulting initial value problem (3.57), (3.27) is, at the same time, a solution of the T-periodic problem (3.57), (3.4).

THEOREM 3.19. *Assume that the T-periodic system of differential Eqs.* (3.57) *satisfies the conditions of Theorem* 3.17.

Then, for an arbitrary $z \in D_\beta$, there exists a unique value of the control parameter μ,

$$\mu = \frac{1}{T}\int_0^T f\bigl(t, x^*(t, z)\bigr)\,\mathrm{d}t, \tag{3.59}$$

such that the solution $x = x(t, 0, z, \mu)$ of the initial value problem (3.57), (3.58), *with μ given by* (3.59), *is a T-periodic function and*

$$x(t, 0, z, \mu) = x^*(t, z) = \lim_{m\to\infty} x_m(t, z), \tag{3.60}$$

where $\{x_m(\cdot, z)\}_{m\geqslant 0}$ is the sequence of functions defined by formula (3.29).

PROOF. Since (3.1) satisfies conditions (3.5), (3.6), (3.61), and (3.62), the sequence of T-periodic functions given by (3.29) converges to a T-periodic function $x^*(\cdot, z)$ uniformly in domain (3.39). It follows from Theorem 3.17 that, according (3.42), (3.43), if (3.59) holds, then the T-periodic solution $x = x^*(t, z)$ of system (3.57) also satisfies the initial value condition (3.56). Thus, we have found the value of the parameter μ of the form (3.59) for which (3.60) holds.

It can be shown that this parameter value is unique because, for any other value $\mu = \nu$, the solution $x = x(t, 0, z, \nu)$ of the initial value problem (3.27) for the differential system

$$x'(t) = f\bigl(t, x(t)\bigr) - \nu, \quad t \in [0, T], \tag{3.61}$$

where $\nu \neq \Delta(z)$ and z satisfies (3.58), does not satisfy the T-periodic boundary condition (3.4). Indeed, assume the contrary. Then there exist at least two values μ, ν $(\mu \neq \nu)$ such that the solutions $x = x(t, 0, z, \mu)$ and $x = x(t, 0, z, \nu)$ of the Cauchy problems (3.57), (3.58) and (3.61) respectively also satisfy the T-periodic boundary condition (3.4). Then, by using (3.25), we obtain the following identity for the difference of these functions:

$$\begin{aligned}
&\bigl|x(t,0,z,\mu) - x(t,0,z,\nu)\bigr| \\
&= \biggl|\int_0^t \bigl[f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr]\,\mathrm{d}s \\
&\quad - \frac{t}{T}\int_0^T \bigl[f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr]\,\mathrm{d}s\biggr| \\
&= \biggl|\left(1 - \frac{t}{T}\right)\int_0^t \bigl[f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr]\,\mathrm{d}s \\
&\quad - \frac{t}{T}\int_t^T \bigl[f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr]\,\mathrm{d}s\biggr| \\
&\leqslant \left(1 - \frac{t}{T}\right)\int_0^t \bigl|f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr|\,\mathrm{d}s \\
&\quad + \frac{t}{T}\int_t^T \bigl|f\bigl(s, x(s,0,z,\mu)\bigr) - f\bigl(s, x(s,0,z,\nu)\bigr)\bigr|\,\mathrm{d}s. \qquad (3.62)
\end{aligned}$$

Putting

$$r(t) := \bigl|x(t,0,z,\mu) - x(t,0,z,\nu)\bigr|, \quad t \in [0, T], \tag{3.63}$$

and $\hat{r} := \operatorname{col}(\max_{t\in[0,T]} r_1(t), \dots, \max_{t\in[0,T]} r_n(t))$, and using the Lipschitz condition (3.5), from (3.62) we find

$$r(t) \leqslant K\left[\left(1 - \frac{t}{T}\right)\int_0^t r(s)\,\mathrm{d}s + \frac{t}{T}\int_t^T r(s)\,\mathrm{d}s\right]. \tag{3.64}$$

In view of (3.64), application of Lemma 3.16 yields

$$r(t) \leqslant K\left[\left(1 - \frac{t}{T}\right)\int_0^t \hat{r}\,\mathrm{d}s + \frac{t}{T}\int_t^T \hat{r}\,\mathrm{d}s\right] \equiv \alpha_{1,T}(t)K\hat{r}. \tag{3.65}$$

Taking into account inequality (3.65) and Lemma 3.16 and arguing by induction, from (3.64) we obtain the estimate

$$r(t) \leqslant \alpha_{m+1,T}(t)K^{m+1}\hat{r}, \quad m = 0, 1, 2, \dots, \tag{3.66}$$

where $\alpha_{m,T}(\cdot)$ are positive functions defined by formula (3.35). By virtue of inequality (3.36), relation (3.66) implies

$$r(t) \leqslant \left(\frac{3T}{10}K\right)^m K\bar{\alpha}_{1,T}(t)r_0 = Q^m K\bar{\alpha}_{1,T}(t)\hat{r}, \quad t \in [0, T],$$

where $\bar{\alpha}_{1,T}$ is given by (3.37). Hence, by virtue of estimate (3.46) from Remark 3.18, we obtain

$$\hat{r} \leqslant \frac{5T}{9} Q^m K \hat{r}, \quad m = 1, 2, \ldots. \tag{3.67}$$

On the assumption that the eigenvalues of matrix (3.45) are less than 1, inequality (3.67) is possible only when $\hat{r} = 0$ and, hence, we have $\mu = \nu$ in (3.63). This contradiction proves that (3.59) is the only suitable value of the parameter μ. □

EXAMPLE 3.20. Let us consider the differential system (3.14) from Example 3.8 in domain (3.15) and try to determine approximately the control parameter $\mu = \mu(z)$, for which the solution of the system

$$\begin{aligned} x_1'(t) &= x_2(t) - \mu_1, \\ x_2'(t) &= -x_1(t) - \big(x_2(t)\big)^s \sin 20t + \cos 20t - \mu_2, \quad t \in [0, T], \end{aligned} \tag{3.68}$$

such that

$$x_1(0) = z_1, \qquad x_2(0) = z_2, \tag{3.69}$$

where $(z_1, z_2) \in D_{\frac{T}{2}M}$, is periodic with period $T = \frac{\pi}{10}$.

Assume that s in (3.14) and a in (3.15) satisfy inequalities (3.17) and (3.18). Then we can seek for the control

$$\mu(z) = \operatorname{col}\big(\mu_1(z), \mu_2(z)\big)$$

as the limit

$$\mu(z) = \lim_{m\to\infty} \mu_m(z) \tag{3.70}$$

of the successive approximations

$$\mu_m(z) = \operatorname{col}\big(\mu_{1m}(z), \mu_{2m}(z)\big), \quad m = 0, 1, 2, \ldots,$$

defined by the equality

$$\mu_m(z) = \frac{1}{T} \int_0^T f\big(t, x_m(t, z)\big)\, \mathrm{d}t$$

with f given by formula (3.16). Thus, we have

$$\begin{aligned} \mu_1(z) &= \lim_{m\to\infty} \frac{10}{\pi} \int_0^{\frac{\pi}{10}} x_{2m}(t, z)\, \mathrm{d}t, \\ \mu_2(z) &= \lim_{m\to\infty} \frac{10}{\pi} \int_0^{\frac{\pi}{10}} \big[-x_{1m}(t, z) - \sin 20t \big(x_{2m}(t, z)\big)^s + \cos 20t\big]\, \mathrm{d}t, \end{aligned}$$

where $x_m(t,z) = \operatorname{col}(x_{1m}(t,z), x_{2m}(t,z))$,

$$x_{10}(t,z) = z_1, \qquad x_{20}(t,z) = z_2,$$

and, for all $m = 1, 2, \dots$ and $t \in [0, T]$,

$$x_{1m}(t,z) = z_1 + \int_0^t x_{2,m-1}(t,z)\,\mathrm{d}t - \frac{10t}{\pi}\int_0^{\frac{\pi}{10}} x_{2,m-1}(t,z)\,\mathrm{d}t, \tag{3.71}$$

$$\begin{aligned} x_{2m}(t,z) &= z_2 + \int_0^t \bigl[-x_{1,m-1}(t,z) - \sin 20t\bigl(x_{2,m-1}(t,z)\bigr)^s + \cos 20t\bigr]\,\mathrm{d}t, \\ &\quad - \frac{10t}{\pi}\int_0^{\frac{\pi}{10}} \bigl[-x_{1,m-1}(t,z) - \sin 20t\bigl(x_{2,m-1}(t,z)\bigr)^s + \cos 20t\bigr]\,\mathrm{d}t. \end{aligned} \tag{3.72}$$

Let us compute the value of the control parameter for system (3.14) with $s = 1$ (i.e., when (3.14) is a linear system with periodic coefficients) and $a = 2$. In this case (see Example 3.8), we have

$$\begin{aligned} D &= \bigl\{(x_1, x_2) \mid |x_1| \leqslant 2, |x_2| \leqslant 1\bigr\}, \\ D_{\frac{\pi}{20}M} &= \left\{(x_1, x_2) \;\middle|\; |x_1| \leqslant 2 - \frac{\pi}{20}, |x_2| \leqslant 1 - \frac{\pi}{5}\right\}. \end{aligned} \tag{3.73}$$

Let us put, e.g.,

$$z_1 = \frac{3}{2}, \qquad z_2 = \frac{1}{4} \tag{3.74}$$

in the initial value condition (3.69). It is easy to see that the vector (z_1, z_2) defined by (3.74) belongs to set (3.73).

According to (3.71) with $m = 1$, the first coordinate of the first approximation $x_1(\cdot, z)$ has the form

$$x_{11}(t,z) = \frac{3}{2} + \int_0^t \frac{1}{4}\,\mathrm{d}t - \frac{10t}{\pi}\int_0^{\frac{\pi}{10}} \frac{1}{4}\,\mathrm{d}t = \frac{3}{2}.$$

Quite similarly, (3.72) yields

$$\begin{aligned} x_{21}(t,z) &= \frac{1}{4} + \int_0^t \left[-\frac{3}{2} - \frac{1}{4}\sin 20t + \cos 20t\right]\mathrm{d}t \\ &\qquad - \frac{10t}{\pi}\int_0^{\frac{\pi}{10}} \left[-\frac{3}{2} - \frac{1}{4}\sin 20t + \cos 20t\right]\mathrm{d}t \\ &= \frac{19}{80} + \frac{1}{80}\cos 20t + \frac{1}{20}\sin 20t. \end{aligned} \tag{3.75}$$

Therefore, in view of (3.70), the control parameters μ_1, μ_2, in the first approximation, have the following values:

$$\mu_{11} = \frac{10}{\pi}\int_0^{\frac{\pi}{10}}\left[\frac{19}{80} + \frac{1}{80}\cos 20t + \frac{1}{20}\sin 20t\right]\mathrm{d}t = \frac{19}{80}$$
$$\approx 0.2125,$$
$$\mu_{21} = \frac{10}{\pi}\int_0^{\frac{\pi}{10}}\left[-\frac{3}{2} - \sin 20t\left(\frac{19}{80} + \frac{1}{80}\cos 20t + \frac{1}{20}\sin 20t\right)\right]\mathrm{d}t$$
$$= -\frac{3}{2} - \frac{\pi}{40}.$$

Analogously, by using (3.71), we can easily compute the second approximations to the limit function ($m = 2$):

$$x_{12}(t,z) = \frac{3}{2} + \int_0^t\left[\frac{19}{80} + \frac{1}{80}\cos 20t + \frac{1}{20}\sin 20t\right]\mathrm{d}t$$
$$- \frac{10t}{\pi}\int_0^{\frac{\pi}{10}}\left[\frac{19}{80} + \frac{1}{80}\cos 20t + \frac{1}{20}\sin 20t\right]\mathrm{d}t$$
$$= \frac{601}{400} + \frac{1}{1600}\sin 20t - \frac{1}{400}\cos 20t \tag{3.76}$$

and

$$x_{22}(t,z) = \frac{1}{4} + \int_0^t\left[-\frac{3}{2} - \sin 20t\left(\frac{19}{80} + \frac{1}{80}\cos 20t\right.\right.$$
$$\left.\left. + \frac{1}{20}\sin 20t + \cos 20t\right) + \cos 20t\right]\mathrm{d}t$$
$$- \frac{10t}{\pi}\int_0^{\frac{\pi}{10}}\left[-\frac{3}{2} - \sin 20t\left(\frac{19}{80} + \frac{1}{80}\cos 20t\right.\right.$$
$$\left.\left. + \frac{1}{20}\sin 20t + \cos 20t\right) + \cos 20t\right]\mathrm{d}t$$
$$= \frac{1523}{6400} + \frac{19}{1600}\cos 20t + \frac{1}{20}\sin 20t + \frac{1}{6400}\cos 40t + \frac{1}{1600}\sin 40t.$$

The control parameters μ_1, μ_2, in the second approximation, are given by the formulae

$$\mu_{12} = \frac{10}{\pi}\int_0^{\frac{\pi}{10}}\left[\frac{1523}{6400} + \frac{19}{1600}\cos 20t + \frac{1}{20}\sin 20t\right.$$
$$\left. + \frac{1}{6400}\cos 40t + \frac{1}{1600}\sin 40t\right] = \frac{1523}{6400} \approx 0.2379,$$

and

$$\mu_{22} = \frac{10}{\pi}\int_0^{\frac{\pi}{10}}\Bigg[-\frac{3}{2} - \frac{1}{1600}\sin 20t + \frac{1}{400}\cos 20t$$
$$- \sin 20t\left(\frac{1523}{6400} + \frac{19}{1600}\cos 20t + \frac{1}{20}\sin 20t\right.$$
$$\left.+ \frac{1}{6400}\cos 40t + \frac{1}{1600}\sin 40t\right)\Bigg]\,\mathrm{d}t = -\frac{3}{2} - \frac{\pi}{400}.$$

Note that (3.75) and (3.76) are the first and second approximations to the exact solution of the initial value problem (3.68), (3.74) with z_1, z_2 given by (3.74). One can verify that an exact solution of this problem exists for control parameter

$$\mu = \mathrm{col}(\mu_1, \mu_2) = \mathrm{col}\left(\frac{1}{4}, -\frac{3}{2}\right).$$

This solution, at the same time, is a $\frac{\pi}{10}$-periodic function as well as $x^*(t, z)$ and satisfies the initial value conditions (3.69) with z_1, z_2 given by (3.74). Higher order approximations can be found in a similar way by using formulae (3.70), (3.71).

Let us find necessary and sufficient conditions for the limit function $x^*(\cdot, z)$ of sequence (3.29) to be a solution of the original T-periodic boundary value problem n (3.3), (3.4).

THEOREM 3.21. *For the T-periodic boundary value problem* (3.3), (3.4), *let conditions* (3.5)–(3.7), *and* (3.8) *hold. Then the solution $x = x(\cdot, 0, z)$ of the Cauchy problem* (3.3), (3.27) *with $z \in D_{\frac{T}{2}M}$ is a solution of the T-periodic problem* (3.3), (3.4) *if, and only if the equality*

$$\int_0^T f\big(t, x^*(t, z)\big)\,\mathrm{d}t = 0, \tag{3.77}$$

holds, where $x^*(\cdot, z)$ is the limit function of sequence (3.29). *Moreover, in this case*

$$x(t, 0, z) \equiv x^*(t, z) \tag{3.78}$$

and for all $m = 1, 2, \ldots$ inequality (3.44) *holds for the deviation of the exact solution* (3.78) *of the T-periodic boundary value problem* (3.3), (3.4) *from its approximate T-periodic solution $x = x_m(\cdot, z)$ given by* (3.29) .

PROOF. The sufficiency of condition (3.77) follows immediately from the fact that the limit function $x^*(\cdot, z)$ satisfying the periodic boundary condition (3.4). and the initial value condition (3.27), is a solution of the integral equation (3.41) or, which is the same, of the integro-differential equations (3.42), (3.43). Obviously, if (3.43) is true, this condition is sufficient for $x^*(\cdot, z)$ to be a solution both of the periodic boundary value problem (3.3), (3.4) and the initial value problem (3.3), (3.27). In this case, (3.78) holds.

The necessity of condition (3.77) follows from the fact that if the solution $x = x(\cdot, 0, x_0)$ of (3.3), (3.27) is a solution of the T-periodic boundary value problem (3.3), (3.4), then the solution $x = x(\cdot, 0, z, \Delta)$ of system (3.42) with the same initial value $x(0, 0, z, \Delta) = z$ is T-periodic provided that $\Delta(z) = 0$ because, in this case,

$$x(t, 0, z, 0) \equiv x(t, 0, z) \equiv x^*(t, z) \tag{3.79}$$

and estimate (3.44) holds.

According to Theorem 3.19, a solution $x = x(t, 0, z, \mu)$ of the Cauchy problem (3.57), (3.58) is, at the same time, a T-periodic function only for the parameter value μ of the form (3.59). However, we already have this value of the parameter when$\mu = \Delta(z) = 0$. The theorem is proved. □

Let us show that the function $x^*(\cdot, z)$ is Lipschitzian with respect to z.

THEOREM 3.22. *Under the assumptions of Theorem* 3.17, *the function* $x^*(\cdot, z)$ *satisfies the following Lipschitz condition for all* $\{y, z\} \subset D_{\frac{T}{2}M}$ *and* $t \in [0, T]$:

$$\left|x^*(t, z) - x^*(t, y)\right| \leqslant \left[I + \bar{\alpha}_{1,T}(t) K (I - Q)^{-1}\right] |z - y|, \tag{3.80}$$

where $\bar{\alpha}_{1,T}$ *is the function* (3.37) *and the matrix* Q *is given by* (3.45).

PROOF. It follows immediately from (3.29) that

$$\begin{aligned} x_1(t, z) - x_1(t, y) &= (z - y) + \int_0^t \left[f(s, z) - f(s, y)\right] \mathrm{d}s \\ &\quad - \frac{t}{T} \int_0^T \left[f(s, z) - f(s, y)\right] \mathrm{d}s \\ &= (z - y) + \left(1 - \frac{t}{T}\right) \int_0^t \left[f(s, z) - f(s, y)\right] \mathrm{d}s \\ &\quad - \frac{t}{T} \int_t^T \left[f(s, z) - f(s, y)\right] \mathrm{d}s. \end{aligned} \tag{3.81}$$

Taking into account identity (3.81), the Lipschitz condition (3.5), and formula (3.35) of Lemma 3.16, we obtain

$$\begin{aligned} \left|x_1(t, z) - x_1(t, y)\right| &\leqslant |z - y| + \left[\left(1 - \frac{t}{T}\right) \int_0^t \mathrm{d}s + \frac{t}{T} \int_t^T \mathrm{d}s\right] K |z - y| \\ &= \left[I + \alpha_{1,T}(t) K\right] |z - y|. \end{aligned} \tag{3.82}$$

Similarly,

$$\begin{aligned}\left|x_2(t,z)-x_2(t,y)\right| \leqslant |z-y| + K\Bigg[\left(1-\frac{t}{T}\right)\int_0^t \left|x_1(s,z)-x_1(s,y)\right| \mathrm{d}s \\ + \frac{t}{T}\int_t^T \left|x_1(s,z)-x_1(s,y)\right| \mathrm{d}s\Bigg].\end{aligned}$$

Taking into account (3.82) and the recurrence relation (3.35), we get

$$\begin{aligned}\left|x_2(t,z)-x_2(t,y)\right| &\leqslant |z-y| + K\Bigg[\left(1-\frac{t}{T}\right)\int_0^t \left|\left(I+\alpha_{1,T}(s)K\right)\mathrm{d}s\right| \mathrm{d}s \\ &\quad + \frac{t}{T}\int_t^T \left(I+\alpha_{1,T}(s)K\right)\mathrm{d}s\Bigg] \\ &\leqslant \left[I+\alpha_{1,T}(t)K+\alpha_{2,T}(t)K^2\right]|z-y|.\end{aligned}$$

From these relations we conclude by induction that

$$\begin{aligned}\left|x_m(t,z)-x_m(t,y)\right| \leqslant \big(I+\alpha_{1,T}(t)K+\alpha_{2,T}(t)K^2 \\ + \cdots + \alpha_{m,T}(t)K^m\big)|z-y|. \qquad (3.83)\end{aligned}$$

Condition (3.7) means that the spectral radius $r(Q)$ of the matrix Q defined by (3.45) is less than 1. Passing to the limit as $m \to +\infty$ in (3.83) and using condition (3.7) together with estimate (3.36) of Lemma 3.16, we obtain

$$\begin{aligned}\left|x^*(t,z)-x^*(t,y)\right| &\leqslant \left(I+\bar{\alpha}_{1,T}(t)\sum_{i=0}^{\infty} K\left(\frac{3T}{10}K\right)^i\right)|z-y| \\ &= \left[I+\bar{\alpha}_{1,T}(t)K(I-Q)^{-1}\right]|z-y|,\end{aligned}$$

i.e., inequality (3.80) holds. □

When the set $D_{\frac{T}{2}M}$ given by (3.8) is not a singleton, to our T-periodic problem (3.3), (3.4) one can associate the “determining function”

$$\Delta : D_{\frac{T}{2}M} \to \mathbb{R}^n \qquad (3.84)$$

defined by formula (3.43).

Assuming that $D_{\frac{T}{2}M}$ contains more than one point, we now establish some properties of the determining function (3.84).

THEOREM 3.23. *Under the conditions of Theorem* 3.17, *the function*

$$D_{\frac{T}{2}M} \ni z \longmapsto \Delta(z) := \frac{1}{T}\int_0^T f\left(t, x^*(t,z)\right)\mathrm{d}t, \qquad (3.85)$$

where $x^*(\cdot, z)$ *is the limit function of sequence* (3.29), *is well-defined, continuous, and bounded inside the set* $D_{\frac{T}{2}M}$. *Furthermore, for all* $\{z, y\} \subset D_{\frac{T}{2}M}$, *it satisfies the Lipschitz condition*

$$\left|\Delta(z) - \Delta(y)\right| \leqslant K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]|z - y|. \tag{3.86}$$

PROOF. It follows from Theorem 3.17 that, for every $z \in D_{\frac{T}{2}M}$, the limit function $x^*(\cdot, z)$ of the uniformly convergent sequence (3.29) exists and is continuous. Therefore, when z varies over $D_{\frac{T}{2}M}$, the function Δ is also continuous and bounded,

$$\left|\Delta(z)\right| = \frac{1}{T}\left|\int_0^T f\big(t, x^*(t, z)\big)\,\mathrm{d}t\right| \leqslant \max_{(t,x)\in[0,T]\times D}\left|f(t, x)\right|.$$

Equality (3.85) implies

$$\begin{aligned}\left|\Delta(z) - \Delta(y)\right| &= \frac{1}{T}\left|\int_0^T \big[f\big(t, x^*(t, z)\big) - f\big(t, x^*(t, y)\big)\big]\,\mathrm{d}t\right| \\ &\leqslant \frac{1}{T}K\int_0^T \left|x^*(t, z) - x^*(t, y)\right|.\end{aligned} \tag{3.87}$$

Substituting (3.80) into (3.87), we get

$$\left|\Delta(z) - \Delta(y)\right| \leqslant \frac{1}{T}K\int_0^T \big[I + \bar{\alpha}_{1,T}(t)K(I - Q)^{-1}\big]\,\mathrm{d}t|z - y|. \tag{3.88}$$

Since

$$\int_0^T \bar{\alpha}_{1,T}(t)\,\mathrm{d}t = \frac{10}{9}\int_0^T 2t\left(1 - \frac{t}{T}\right)\mathrm{d}t = \frac{10}{27}T^2, \tag{3.89}$$

inequality (3.88) yields

$$\begin{aligned}\left|\Delta(z) - \Delta(y)\right| &\leqslant K|z - y| + \frac{10T}{27}K^2(I - Q)^{-1}|z - y| \\ &\leqslant K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]|z - y|,\end{aligned}$$

which completes the proof of our theorem. □

REMARK 3.24. Theorem 3.21 gives the following numerical-analytic algorithm for the construction of the T-periodic solutions of the non-autonomous T-periodic system (3.1).

(1) For a $z \in D_{\frac{T}{2}M}$, according to (3.29), we analytically construct the sequence of T-periodic functions $x_m(\cdot, z)$ depending on the parameter z.

(2) We find the limit $x^*(\cdot, z)$ of the sequence $x_m(\cdot, z)$.
(3) We construct the determining function Δ of the form (3.43).
(4) Using a suitable method for the numerical solution of non-linear algebraic or transcendental equations, we (approximately) find the solution(s) $z = z^*$ of the determining equation

$$\Delta(z) = 0 \tag{3.90}$$

lying in the set $D_{\frac{T}{2}M}$.
(5) After the substitution of the obtained value(s) $z = z^*$ into $x^*(\cdot, z)$, we get the (approximate) T-periodic solution(s) in the form $x^*(\cdot, z^*)$. This solution can also be obtained by solving the Cauchy problem $x(0) = z^*$ for the given differential system (3.3).

REMARK 3.25. Under our assumptions, the method under consideration allows one to find all the T-periodic solutions of (3.1) with values in the domain D because, by virtue of Theorem 3.21, the roots of the determining equation (3.90) “detect” the initial values of all the T-periodic solutions.

The principal difficulty in the realisation of the method is related with the analytic construction of the limit function $x^*(\cdot, z)$. However, in a number of cases, this problem can be avoided because, as can be shown, it is possible to prove the existence of a T-periodic solution on base of the properties of a certain approximation $x_m(\cdot, z)$ known in the analytic form.

3.2. *Existence theorems for periodic solutions*

In this section, we establish certain sufficient conditions for the solvability of periodic boundary value problem (3.3), (3.4) using the properties of successive approximations $\{x_m(\cdot, z)\}_{m\geqslant 0}$ of the form (3.29). Then, we indicate some necessary conditions for the existence of T-periodic solutions, i.e., conditions necessary for a certain subset of the set $D_{\frac{T}{2}M}$ to contain a point z^* determining the initial value $x^*(0) = z^*$ of the solution $x^*(\cdot)$ of the T-periodic problem (3.3), (3.4). We describe also the numerical algorithm for selecting these points.

To investigate the solvability of the periodic boundary value problem (3.3), (3.4), in addition to the *determining function* (3.85), we introduce the mth *approximate determining function*

$$D_{\frac{T}{2}M} \ni z \longmapsto \Delta_m(z) := \frac{1}{T} \int_0^T f\big(t, x_m(t, z)\big)\, \mathrm{d}t, \tag{3.91}$$

replacing $x^*(\cdot, z)$ in (3.85) by the function $x_m(\cdot, z)$ given by (3.29).

It is natural to expect that, under suitable conditions, the functions Δ and Δ_m are “close enough” to one another for m sufficiently large.

LEMMA 3.26. *Let us suppose that the function f satisfies assumptions* (3.5)–(3.7), *and* (3.8). *Then, for arbitrary $z \in D_{\frac{T}{2}M}$ and $m \geqslant 0$,*

$$\left|\Delta(z) - \Delta_m(z)\right| \leqslant \frac{10}{27} T K Q^m (I - Q)^{-1} M, \tag{3.92}$$

where the matrix Q and vector M are given by (3.45) *and* (3.6), *respectively.*

PROOF. By virtue of estimate (3.44) and relations (3.85), (3.91), we have

$$\begin{aligned}\left|\Delta(z) - \Delta_m(z)\right| &\leqslant \left|\frac{1}{T}\int_0^T \left[f\big(t, x^*(t,z)\big) - \int_0^T f\big(t, x_m(t,z)\big)\right] \mathrm{d}t\right| \\ &\leqslant \frac{1}{T} K \int_0^T \left|x^*(t,z) - x_m(t,z)\right| \mathrm{d}t \\ &\leqslant \frac{1}{T} K Q^m (I - Q)^{-1} M \int_0^T \bar{\alpha}_{1,T}(t)\, \mathrm{d}t.\end{aligned}$$

Taking (3.89) into account, we arrive at (3.92). □

REMARK 3.27. It is easy to see from Theorem 3.23, Lemma 3.26, and inequality (3.44) that the mappings (3.85), (3.91) are completely continuous.

Let us formulate a statement that establishes sufficient conditions for the solvability of the of the periodic boundary value problem (3.3), (3.4).

THEOREM 3.28. *Let us suppose that, in addition to assumptions* (3.5)–(3.7), *and* (3.8), *there exist a bounded closed subdomain $\Omega \subset D_{\frac{T}{2}M}$ and an number $m \in \mathbb{N}$ such that the approximate determining function* (3.91) *satisfies the following conditions*:

(a) *The relation*

$$\inf_{z \in \partial\Omega} \left|\Delta_m(z)\right| > \frac{10T}{27} K Q^m (I - Q)^{-1} M, \tag{3.93}$$

holds, where Q is the matrix given by (3.45);

(b) *The Brouwer degree*[1] *of Δ_m over Ω with respect to* 0 *satisfies the inequality*

$$\deg(\Delta_m, \Omega, 0) \neq 0. \tag{3.94}$$

Then the periodic boundary value problem (3.3), (3.4) *has a T-periodic solution $x = x^*(\cdot)$ with the initial value $x^*(0)$ belonging to Ω.*

---

[1] See, e.g., [17, Definition A2.5, Definition A2.9] and [81, Section 5].

PROOF. Recall that [17, Theorem A2.5] establishes the invariance of the topological degree by homotopy. Thus, if we show that the vector fields (3.85) and (3.91) are homotopic, then, in view of assumption (3.94),

$$\deg(\Delta, \Omega, 0) = \deg(\Delta_m, \Omega, 0), \tag{3.95}$$

whence we see that

$$\deg(\Delta, \Omega, 0) \neq 0. \tag{3.96}$$

Let us prove that the fields Δ and Δ_m are homotopic. For this purpose, we consider the "linear deformation" determined by the family of mappings

$$P(\theta, z) := \Delta_m(z) + \theta\bigl[\Delta(z) - \Delta_m(z)\bigr], \quad z \in \partial\Omega, \tag{3.97}$$

where $\theta \in [0, 1]$. Obviously, $P(\theta, \cdot)$ is a continuous mapping on $\partial\Omega$ for every θ from $[0, 1]$ and, furthermore,

$$P(0, z) = \Delta_m(z), \qquad P(1, z) = \Delta(z) \tag{3.98}$$

for all $z \in \partial\Omega$.

For an arbitrary z from $\partial\Omega$, in view of (3.98), (3.92), and (3.93), we have

$$\begin{aligned} |P(\theta, z)| &= \bigl|\Delta_m(z) + \theta\bigl[\Delta(z) - \Delta_m(z)\bigr]\bigr| \\ &\geqslant \bigl|\Delta_m(z)\bigr| - \bigl|\Delta(z) - \Delta_m(z)\bigr| > 0, \end{aligned} \tag{3.99}$$

i.e., $P(\theta, \cdot)$ does not vanish on $\partial\Omega$. We see that, being a non-degenerate deformation, (3.97) guarantees that (3.85) and (3.91) are homotopic. Therefore, (3.96) is true.

By [17, Theorem A2.4], inequality (3.96) guarantees the existence of a point $z^* \in \Omega$ such that $\Delta(z^*) = 0$. Consequently, in view of Theorem 3.21, the solution $x = x^*(\cdot)$ of the Cauchy problem

$$x(0) = z^*$$

for Eq. (3.3) is also a solution of the T-periodic boundary value problem (3.3), (3.4). Moreover,

$$x^*(t) = x^*\bigl(t, z^*\bigr), \quad t \in [0, T],$$

where $x^*(\cdot, z^*)$ is the limit function of the T-periodic sequence of functions defined by formula (3.29). □

REMARK 3.29. To verify condition (a) of Theorem 3.28 in concrete cases, one has to use the recurrence formula (3.29) to compute the function $x_m(\cdot, z)$ depending on $z \in \Omega$ as a parameter, construct the corresponding mapping (3.91), and verify whether its topological degree is non-zero.

This is a rather difficult problem in general. However, in a number of important cases, there are relatively simple criteria to study this question. In particular, when Δ_m is an odd mapping, i.e.,

$$\Delta_m(-z) = -\Delta_m(z),$$

for any z, then, according to the Borsuk theorem (see, e.g., [81, p. 174] or [17, Theorem A2.12]), the Brouwer degree $\deg(\Delta_m, \Omega, 0)$ is an odd number and, therefore, is not equal to zero.

Alternatively, it follows directly from [17, Definition A2.1] of the topological degree that if the Jacobian matrix of the function (3.91) is non-degenerate at its isolated zero $z_{m0} \in \Omega$, i.e., if

$$\det \frac{\partial \Delta_m}{\partial z}(z_{m0}) \neq 0,$$

then inequality (3.96) holds.

REMARK 3.30. The assertion of Theorem 3.28 is valid, in particular, for $m = 0$. In this case, condition (3.93) is replaced by the relation

$$\inf_{z \in \partial\Omega} \left| \int_0^T f(t, z)\, \mathrm{d}t \right| > \frac{10T^2}{27} K(I - Q)^{-1} M. \tag{3.100}$$

Here, we do not have to compute any approximations at all. Due to its simplicity, inequality (3.100) may prove convenient for the investigation of periodic solutions with "small" periods.

To seek for points z^* through which the T-periodic solutions of (3.3) pass at $t = 0$, i.e., to search for zeroes of the determining function (3.85), is by no means an easy problem, because the analytic form of this mapping is, in general, unknown. For this reason, one has to use approximate determining functions and apply statements similar to Theorem 3.28. However, there are particular cases where the existence of zeroes of function (3.85) is clear from some other considerations.

Let us consider one of such cases, where the right-hand side function of Eq. (3.1) has a certain symmetric property.

We recall the classical Arzelà–Ascoli theorem (see, e.g., Arzelà [5], Petrovski [58]).

THEOREM 3.31. (See [5].) *Let* $\{x_m(\cdot)\}_{m=1}^{\infty}$ *be a uniformly bounded and equicontinuous sequence of functions on the interval* $[\alpha, \beta]$. *Then it contains a subsequence* $\{x_{m_k}(\cdot)\}_{k=1}^{\infty}$ *uniformly convergent on* $[\alpha, \beta]$.

The uniform boundedness of the sequence means that there exists a positive constant K for which $\max_{t \in [\alpha,\beta]} |x_m(t)| \leqslant K$ independently of $m = 1, 2, \ldots$, whereas its equicontinuity means that, for an arbitrary $\varepsilon > 0$, there exists a $\delta > 0$ such that if $\{t_1, t_2\} \subset [\alpha, \beta]$ satisfy the inequality $|t_1 - t_2| < \delta$, then

$$\sup_{m \geqslant 1} \left| x_m(t_1) - x_m(t_2) \right| < \varepsilon. \quad m = 1, 2, \ldots.$$

The following theorem is a modified version of [89, Theorem 8.1].

THEOREM 3.32. *Let the right-hand side function* $f : \mathbb{R} \times D \to \mathbb{R}^n$ *of the differential system* (3.1) *be defined on* $\mathbb{R} \times D$, *where* D *is the closure of a bounded domain in* $\mathbb{R}^n$, *and let* f *satisfy the following conditions*:

(1) *The function* f *is continuous and periodic of period* T *in the first argument and, with a certain vector* $M \in \mathbb{R}^n_+$, *satisfies condition* (3.6);

(2) *The equality*

$$f(-t, x) = -f(t, x) \tag{3.101}$$

holds for all $t \in (-\infty, \infty)$ *and* $x \in D$;

(3) *Condition* (3.8) *is satisfied*: $D_{\frac{T}{2}M} \neq \varnothing$.

Then, for every $z \in D_{\frac{T}{2}M}$, *system* (3.1) *possesses an even* T*-periodic solution satisfying the initial condition*

$$x(0) = z. \tag{3.102}$$

If, moreover, there exists a non-negative matrix $K \in \mathrm{GL}_n(\mathbb{R})$ *such that* f *satisfies the Lipschitz* (3.5) *for all* $t \in \mathbb{R}$ *and* $\{x_1, x_2\}$ *from* D, *then, for any* $z \in D_{\frac{T}{2}M}$, *system* (3.1) *has no other solutions with property* (3.102) *and graph lying in* D.

In other words, under conditions of Theorem 3.32, the set $D_{\frac{T}{2}M}$ consists of the initial values of T-periodic solutions of system (3.1).

PROOF OF THEOREM 3.32. Let us fix a vector $z \in D_{\frac{T}{2}M}$ and consider the Picard successive approximations

$$x_{m+1}(t) = z + \int_0^t f\bigl(s, x_m(s)\bigr)\, \mathrm{d}s, \quad m = 0, 1, 2, \ldots, \tag{3.103}$$

where $x_0(t) = z$ for all t from $(-\infty, \infty)$.

By assumption, $t \mapsto f(t, z)$ is an odd function for any fixed z and, hence,

$$\int_0^T f(t, z)\, \mathrm{d}t = 0.$$

Therefore, formula (3.103) and the T-periodicity of sequence (3.29) yield

$$x_1(t) = z + \int_0^t \left(f(s, z) - \frac{1}{T} \int_0^T f(\tau, z)\, \mathrm{d}\tau \right) \mathrm{d}s = x_1(t + T) \tag{3.104}$$

for any $t \in (-\infty, \infty)$, i.e., the function x_1 is T-periodic. Let us argue by analogy with the proof of Theorem 3.17. Taking assumption (3.6) into account, we arrive at estimate (3.47), whence, in view of (3.104), it follows that, for all t,

$$\left|x_1(t) - z\right| \leqslant \frac{T}{2} M,$$

i.e., the function x_1 takes values in D. Furthermore, being the integral of an odd function, x_1 is even, i.e., $x_1(t) = x_1(-t)$ for any t from $(-\infty, \infty)$.

Taking assumption (3.6) into account and arguing by induction, one can show that, for an arbitrary $m \geqslant 1$, the function $x_m(\cdot)$ given by formula (3.103) is well-defined on $\mathbb{R}$, periodic with period T, and satisfies the relations

$$\int_0^T f\big(t, x_m(t)\big)\,\mathrm{d}t = 0, \tag{3.105}$$

$$x_m(t) = x_m(-t), \tag{3.106}$$

and (3.48) for all t from $(-\infty, \infty)$.

Inequality (3.48) implies the uniform boundedness of sequence (3.103). The form of sequence (3.103) and the continuity of f on the bounded set $[0, T] \times D$ guarantees the equicontinuity of sequence (3.103). Thus, in view of the Arzelà–Ascoli theorem (Theorem 3.31), we can select a uniformly convergent subsequence $\{x_{m_k} \mid k \geqslant 0\}$ of the sequence of T-periodic functions $\{x_m \mid m \geqslant 0\}$. Hence, the function

$$\lim_{k\to\infty} x_{m_k} =: x \tag{3.107}$$

is well-defined on the entire $\mathbb{R}$. Setting $m = m_k$, $k = 1, 2, \ldots,$ in (3.103), (3.106) and passing to the limit as $k \to +\infty$, we obtain that x is an even function satisfying the differential system (3.1). Moreover, x is periodic with period T because each of the functions x_{m_k}, $k = 1, 2, \ldots,$ has this property and the limit in (3.107) is uniform. Thus, x is an even T-periodic solution of (3.1) satisfying condition (3.102).

Let now f satisfy the Lipschitz condition (3.5) for all $t \in \mathbb{R}$ and $\{x_1, x_2\}$ from D. According to assumption (3.5), the conditions of the Picard–Lindelöf existence and uniqueness theorem (see, for instance [17, Theorem 1.1.1]) hold, whence the uniqueness of the solution in question follows. □

EXAMPLE 3.33. Let us apply the results above to study the 1-periodic solutions of the system

$$\begin{aligned} x_1'(t) &= a x_2(t) \sin 4\pi t, \\ x_2'(t) &= b\big(x_1(t)\big)^2 \sin 2\pi t + \sin 4\pi t, \qquad t \in [0, T], \end{aligned} \tag{3.108}$$

where $a \neq 0$, $b \in \mathbb{R}$, $T = 1$.

It is obvious that property (3.101) holds for the right-hand side of (3.108). Let the system be defined in the domain

$$(t,x) \in [0,T] \times D, \quad D\colon |x_1| \leqslant A, |x_2| \leqslant B. \tag{3.109}$$

Then

$$\bigl|f(t,x)\bigr| \leqslant \operatorname{col}\bigl(|a|B, 1+|b|A^2\bigr). \tag{3.110}$$

The set (3.8) for system (3.108) is defined as follows:

$$D_{\frac{T}{2}M} = \left\{(x_1,x_2) \,\middle|\, |x_1| \leqslant A - \frac{1}{2}|a|B, |x_2| \leqslant B - \frac{1}{2}\bigl[1+|b|A^2\bigr]\right\}. \tag{3.111}$$

This set is non-empty if

$$\begin{aligned} &A - \frac{1}{2}|a|B \geqslant 0, \\ &B - \frac{1}{2}\bigl[1+|b|A^2\bigr] \geqslant 0, \end{aligned}$$

i.e., when

$$\frac{1}{2} + \frac{1}{2}|b|A^2 \leqslant B \leqslant \frac{2A}{|a|}. \tag{3.112}$$

The Lipschitz condition (3.5) holds with the matrix

$$K = \begin{bmatrix} 0 & |a| \\ 2b|A| & 0 \end{bmatrix}.$$

Consequently, if our domain satisfies condition (3.112), by virtue of Theorem 3.32, every solution $x(t)$ of system (3.108) with the initial value $x(0)$ lying in domain (3.111) is periodic with period 1. For instance, if

$$a = \frac{1}{2}, \quad b = -1, \quad A = 1,$$

and, according to (3.112),

$$1 \leqslant B \leqslant 4,$$

then the set

$$D_{\frac{T}{2}M} = \left\{(x_1,x_2) \,\middle|\, |x_1| \leqslant 1 - \frac{B}{4}, |x_2| \leqslant B - 1\right\}$$

consists of the initial values of 1-periodic solutions of system (3.108). In particular, for $A = 1$ and $B = 3$, all points from the set

$$D_{\frac{T}{2}M} = \left\{ (x_1, x_2) \;\middle|\; |x_1| \leqslant \frac{1}{4}, |x_2| \leqslant 2 \right\}$$

can serve as the initial values of 1-periodic solutions of system (3.108).

Let us find the first approximation of the 1-periodic solutions of the given system (3.108), supposing that the parameters a, b and the domain (3.109) such that the inequalities (3.112) are true and the vector of initial values $z = \operatorname{col}(z_1, z_2)$ belongs to subset $D_{\frac{T}{2}M}$ of the form (3.111). According to formula (3.103) for $m = 0$ we get:

$$\begin{aligned} x_{11}(t) &= z_1 + \int_0^t a z_2 \sin 4\pi s \,\mathrm{d}s = \left(z_1 + \frac{a z_2}{4\pi} \right) - \frac{a z_2}{4\pi} \cos 4\pi t, \\ x_{21}(t) &= z_2 + \int_0^t \left[b z_1^2 \sin 2\pi s + \sin 4\pi s \right] \mathrm{d}s \\ &= \left(z_2 + \frac{b z_1^2}{2\pi} + \frac{1}{4\pi} \right) - \frac{b z_1^2}{2\pi} \cos 2\pi t - \frac{\cos 4\pi t}{4\pi}. \end{aligned} \tag{3.113}$$

Similarly to (3.113) one can easily get the second approximation.

EXAMPLE 3.34. Consider the damped Duffing equation with periodic forcing term (see (4.3.15) in [17])

$$x''(t) + d x'(t) + a x + b\big(x(t)\big)^3 = H \sin \frac{2\pi t}{T}, \quad t \in [0, T], \tag{3.114}$$

for some $T > 0$, $d \in \mathbb{R}$, $a \in \mathbb{R}$, $H \in \mathbb{R}$, $b \in \mathbb{R}$ (if $b > 0$ this is the "hard spring case," and if $b < 0$ this is the "soft spring case"). Rewriting the differential equation (3.114) in the Cauchy normal form, we get

$$\begin{aligned} x_1'(t) &= x_2(t), \\ x_2'(t) &= H \sin \frac{2\pi t}{T} - d x_2(t) - a x_1(t) - b\big(x_1(t)\big)^3. \end{aligned} \tag{3.115}$$

Let the system (3.115) be defined for (t, x) from $[0, T] \times D$, where

$$D = \big\{ (x_1, x_2) \mid |x_1| \leqslant A, |x_2| \leqslant B \big\}. \tag{3.116}$$

Then

$$\big| f(t, x) \big| \leqslant \operatorname{col}\big(B, |H| + |d| B + |a| A + |b| A^3 \big).$$

The subset (3.8) for system (3.115) is given by the formula

$$
\begin{aligned}
D_{\frac{T}{2}M} = \Big\{ (x_1, x_2) \,\Big|\, |x_1| \leqslant A - \frac{T}{2} B, \\
|x_2| \leqslant B - \frac{T}{2}\big[|H| + |d|B + |a|A + |b|A^3\big] \Big\},
\end{aligned}
\tag{3.117}
$$

which is non-empty if

$$
\begin{aligned}
&A - \frac{T}{2} B \geqslant 0, \\
&B - \frac{T}{2}\big[|H| + |d|B + |a|A + |b|A^3\big] \geqslant 0,
\end{aligned}
$$

i.e., when

$$
\begin{aligned}
&\frac{T}{2 - T|d|}\big[|H| + |a|A + |b|A^3\big] \leqslant B \leqslant \frac{2}{T} A, \\
&T|d| < 2.
\end{aligned}
\tag{3.118}
$$

The Lipschitz condition (3.5) is fulfilled for system (3.115) with the matrix

$$
K = \begin{bmatrix} 0 & 1 \\ |a| + 3|b|A^2 & |d| \end{bmatrix},
\tag{3.119}
$$

whose greatest eigenvalue is equal to

$$
r(K) = \frac{|d|}{2} + \sqrt{\frac{d^2}{4} + |a| + 3|b|A^2}.
$$

Therefore, the maximal eigen-value of the matrix Q of the form (3.45) is less that 1 if

$$
\frac{|d|}{2} + \sqrt{\frac{d^2}{4} + |a| + 3|b|A^2} < \frac{10}{3T}.
\tag{3.120}
$$

Thus, for system (3.115), conditions (3.5)–(3.7), and (3.8) hold in domain (3.116) if the parameters in Eq. (3.114) satisfy inequalities (3.117)–(3.120). If, for instance,

$$
T = \frac{1}{2}, \quad b = 2, \quad d = 1, \quad a = 1, \quad H = 1, \quad A = 1
\tag{3.121}
$$

(the “hard spring case”), the domain D is

$$
D = \big\{ (x_1, x_2) \mid |x_1| \leqslant 1, |x_2| \leqslant B \big\}
\tag{3.122}
$$

and, according to (3.118),

$$\frac{4}{3} \leqslant B \leqslant 4.$$

In particular, for $B = 2$ the subset $D_{\frac{T}{2}M}$ has the form

$$D_{\frac{T}{2}M} = \left\{ (x_1, x_2) \;\middle|\; |x_1| \leqslant \frac{1}{2}, |x_2| \leqslant \frac{1}{2} \right\} \tag{3.123}$$

and, thus, the initial value of the $\frac{1}{2}$-periodic solution must belong to the set (3.123). The successive approximations (3.29) are well-defined. So, the first approximation has the form:

$$\begin{aligned} x_{11}(t, z) &= z_1 + \int_0^t \left[z_2 - \frac{1}{T} \int_0^T z_2 \, \mathrm{d}\tau \right] \mathrm{d}s = z_1, \\ x_{21}(t, z) &= z_2 + \int_0^t \left[H \sin \frac{2\pi}{T} s - d z_2 - a z_1 - b z_1^3 \right. \\ &\qquad \left. - \frac{1}{T} \int_0^T \left(H \sin \frac{2\pi}{T} \tau - d z_2 - a z_1 - b z_1^3 \right) \mathrm{d}\tau \right] \mathrm{d}s \\ &= z_2 + \frac{HT}{2\pi} - \frac{HT}{2\pi} \cos \frac{2\pi}{T} t = z_2 + \frac{1}{4\pi} - \frac{1}{4\pi} \cos 4\pi t. \end{aligned} \tag{3.124}$$

The first approximation to the determining equation of the form (3.91) is

$$\begin{aligned} \Delta_{11}(z) &= \frac{1}{T} \int_0^T \left[z_2 + \frac{1}{4\pi} - \frac{1}{4\pi} \cos 4\pi t \right] \mathrm{d}t \\ &= z_2 + \frac{1}{4\pi} = 0, \\ \Delta_{21}(z) &= \frac{1}{T} \int_0^T \left[\sin 4\pi t - \left(-\frac{1}{4\pi} + \frac{1}{4\pi} - \frac{1}{4\pi} \cos 4\pi t \right) - z_1 - 2 z_1^3 \right] \mathrm{d}t \\ &= -z_1 - 2 z_1^3 = 0, \end{aligned} \tag{3.125}$$

whence

$$z_2 = -\frac{1}{4\pi}, \qquad z_1 = 0.$$

Thus, the initial value of the $\frac{1}{2}$-periodic solution of system (3.115), in the first approximation, is

$$\operatorname{col}(z_1, z_2) = \operatorname{col}\left(0, -\frac{1}{4\pi}\right).$$

Let us take, instead of (3.121), the following values:

$$T = \frac{1}{2}, \quad b = -1, \quad d = 1, \quad a = \frac{1}{9}, \quad H = 1, \quad A = 1 \tag{3.126}$$

(the "soft spring case"). Then, in view of (3.118), the domain D is given by (3.122), where

$$\frac{19}{27} < B \leqslant 4. \tag{3.127}$$

In particular, for $A = 1$ and $B = 2$ the subset $D_{\frac{T}{2}M}$ is the following:

$$D_{\frac{T}{2}M} = \left\{ (x_1, x_2) \,\middle|\, |x_1| \leqslant \frac{1}{2}, |x_2| \leqslant \frac{19}{28} \right\}. \tag{3.128}$$

Taking into account (3.29) and performing the computation, we obtain that the first approximation is also given by formula (3.124). However, instead of (3.125), we have

$$\begin{aligned} \Delta_{21}(z) &= \frac{1}{T} \int_0^T \left[\sin 4\pi t + \frac{1}{4\pi} \cos 4\pi t - \frac{1}{9} z_1 + z_1^3 \right] \mathrm{d}t \\ &= -\frac{1}{9} z_1 + z_1^3 = 0, \end{aligned}$$

whence

$$z_1 \left(-\frac{1}{9} + z_1^2 \right) = 0, \quad z_1^{(1)} = 0, \quad z_1^{(2)} = \frac{1}{3}, \quad z_1^{(3)} = -\frac{1}{3}.$$

Thus, for the Duffing equation (3.114), (3.126) (the "soft spring case"), in the domain (3.128), on base of the first approximation, we find three initial values for the $\frac{1}{2}$-periodic solutions:

$$\begin{aligned} &\operatorname{col}(z_1, z_2) = \operatorname{col}\left(0, -\frac{1}{4\pi} \right), \\ &\operatorname{col}(z_1, z_2) = \operatorname{col}\left(\frac{1}{3}, -\frac{1}{4\pi} \right), \qquad \operatorname{col}(z_1, z_2) = \operatorname{col}\left(-\frac{1}{3}, -\frac{1}{4\pi} \right). \end{aligned} \tag{3.129}$$

Note that it is impossible to apply the results of Rouche and Mawhin [81] (see also Theorem 4.3.4 in Farkas [17]) to study the Duffing differential equation (3.114) with parameters (3.121), (3.126) in the domain D: $|x_1| \leqslant 1$, $|x_2| \leqslant 2$, because we assume that the "hard spring case" ($b > 0$) may take place and, moreover, the inequalities

$$aA + bA^3 + H \sin \omega t < 0, \quad -aA - bA^3 + H \sin \omega t > 0$$

of the mentioned [17, Theorem 4.3.4] (see also Corollary 5.6 from [81, p. 195]) do not hold in the domain D under consideration. These inequalities may hold in a "smaller" domain. So, this approach adds to the possibilities of investigation of the Duffing type equation (3.114).

EXAMPLE 3.35. Let us investigate the T-periodic solution of the non-autonomous Van der Pol equation with a periodic forcing term of the form

$$x''(t) + a\big(\big(x(t)\big)^2 - 1\big)x'(t) + x(t) = H \sin \omega t, \quad t \in [0, T], \tag{3.130}$$

where $T = 2\pi\omega^{-1}$, $a \in \mathbb{R}$, $H \in \mathbb{R}$. Equation (3.130) can be rewritten as the system

$$\begin{aligned} x_1'(t) &= x_2(t), \\ x_2'(t) &= H \sin \omega t - a\big(\big(x_1(t)\big)^2 - 1\big)x_2(t) - x_1(t), \quad t \in [0, T], \end{aligned} \tag{3.131}$$

which is considered in $[0, T] \times D$ with

$$D = \big\{(x_1, x_2) \mid |x_1| \leqslant A, |x_2| \leqslant B\big\}. \tag{3.132}$$

It is easy to see that f, the right-hand side function in (3.131), satisfies the estimate

$$\big|f(t, x)\big| \leqslant \operatorname{col}\big(B, |H| + |a|\big(A^2 + 1\big)B + A\big) \tag{3.133}$$

for any $(t, x) \in [0, T] \times D$. For M, we can thus take the term from the right-hand side of (3.133). Then

$$\begin{aligned} D_{\frac{T}{2}M} = \bigg\{(x_1, x_2) \,\bigg|\, & |x_1| \leqslant A - \frac{T}{2}B, \\ & |x_2| \leqslant B - \frac{T}{2}\big[|H| + |a|(A^2 + 1)B + A\big]\bigg\}. \end{aligned} \tag{3.134}$$

The set $D_{\frac{T}{2}M}$ is non-empty if

$$A - \frac{T}{2}B \geqslant 0, \tag{3.135}$$

$$B - \frac{T}{2}\big[|H| + |a|(A^2 + 1)B + A\big] \geqslant 0. \tag{3.136}$$

It is easy to see that inequalities (3.135) and (3.136) hold whenever

$$\frac{T[|H| + A]}{2 - T|a|(A^2 + 1)} \leqslant B \leqslant \frac{2}{T}A, \tag{3.137}$$

for a and A such that $T|a|(A^2 + 1) < 2$.

For the system (3.131) the Lipschitz condition (3.5) holds with the matrix

$$K = \begin{bmatrix} 0 & 1 \\ 1+2|a|AB & |a|\bigl(A^2+1\bigr) \end{bmatrix},$$

whose eigenvalues λ are given by the equalities

$$\lambda = \frac{|a|(A^2+1)}{2} \pm \sqrt{\frac{a^2(A^2+1)^2}{4} + 1 + 2|a|AB}.$$

The greatest eigenvalue of the matrix Q of the form (3.45) is, therefore, less then 1 whenever

$$|a|\bigl(A^2+1\bigr) + \sqrt{a^2\bigl(A^2+1\bigr)^2 + 4 + 8|a|AB} < \frac{20}{3T}. \tag{3.138}$$

Thus, conditions (3.5), (3.6), (3.7), and (3.8) are fulfilled for system (3.131) in domain (3.132) if (3.134), (3.137), and (3.138) are true. For instance, if

$$T = 1, \quad \omega = 2\pi, \quad a = -\frac{1}{2}, \quad A = 1, \quad H = \frac{1}{2}, \tag{3.139}$$

then (3.137) means that $\frac{3}{2} \leqslant B \leqslant 2$. Specifically, for the domain

$$D = \left\{ (x_1, x_2) \;\middle|\; |x_1| \leqslant 1 = A, |x_2| \leqslant \frac{7}{4} \right\} \tag{3.140}$$

corresponding to $B = \frac{7}{4}$, set (3.134) is given by the formula

$$D_{\frac{T}{2}M} = \left\{ (x_1, x_2) \;\middle|\; |x_1| \leqslant \frac{1}{8}, |x_2| \leqslant \frac{1}{8} \right\}. \tag{3.141}$$

Thus, for the Van der Pol system (3.131) conditions (3.5)–(3.140) with parameters (3.139), (3.141) and, hence, the successive approximations (3.29) are well-defined.

According to (3.29), the first approximation is

$$\begin{aligned} x_{11}(t,z) &= z_1 + \int_0^t \left[z_2 - \int_0^1 z_2 \,\mathrm{d}\tau \right] \mathrm{d}s = z_1, \\ x_{21}(t,z) &= z_2 + \int_0^t \left[\frac{1}{2}\sin 2\pi t + \frac{1}{2}\bigl(z_1^2 - 1\bigr) z_2 - z_1 \right. \\ &\qquad \left. - \int_0^1 \left(\frac{1}{2}\sin 2\pi\tau + \frac{1}{2}\bigl(z_1^2-1\bigr)z_2 - z_1 \right) \mathrm{d}\tau \right] \mathrm{d}s \\ &= z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t. \end{aligned}$$

The first approximation to determining equation (3.91) has the form

$$\Delta_{11}(z) = \int_0^1 \left[z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 4\pi t \right] \mathrm{d}t = z_2 + \frac{1}{4\pi} = 0,$$

$$\Delta_{21}(z) = \int_0^1 \left[\frac{1}{2}\sin 2\pi t + \frac{1}{2}\big(z_1^2 - 1\big)\left(z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t \right) - z_1 \right] \mathrm{d}t$$
$$= \int_0^1 \left[-\frac{1}{8\pi} z_1^2 + \frac{1}{8\pi} + \frac{1}{8\pi} z_1^2 - \frac{1}{8\pi} - z_1 \right] \mathrm{d}t = 0,$$

whence we find that

$$z_2 = -\frac{1}{4\pi}, \qquad z_1 = 0.$$

So, the approximate initial value of the 1-periodic solution of the Van der Pol system (3.131), (3.139) is given by the formula

$$\operatorname{col}(z_1, z_2) = \operatorname{col}\left(0, -\frac{1}{4\pi} \right).$$

The components of the second approximation are:

$$x_{12}(t, z) = z_1 + \int_0^t \left[z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t - \int_0^1 \left(z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi s \right) \right] \mathrm{d}t = z_1 - \frac{1}{8\pi^2}\sin 2\pi t,$$

$$x_{22}(t, z) = z_2 + \int_0^t \left[\frac{1}{2}\sin 2\pi t + \frac{1}{2}\big(z_1^2 - 1\big)\left(z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t \right) - z_1 - \int_0^1 \left[\frac{1}{2}\sin 2\pi s + \frac{1}{2}\big(z_1^2 - 1\big)\left(z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi s \right) - z_1 \right] \mathrm{d}s \right] \mathrm{d}t$$
$$= z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t - \frac{1}{16\pi^2}\big(z_1^2 - 1\big)\sin 2\pi t,$$

whereas the second approximate determining system

$$\Delta_{12}(z) = \int_0^1 \left[z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t - \frac{1}{16\pi^2}(z_1^2 - 1)\sin 2\pi t \right] \mathrm{d}t$$
$$= z_2 + \frac{1}{4\pi} = 0,$$

$$\begin{aligned}\Delta_{22}(z) &= \int_0^1 \biggl[\frac{1}{2}\sin 2\pi t + \frac{1}{2}\biggl(z_1^2 - \frac{1}{4\pi^2}\sin 2\pi t + \frac{1}{64\pi^4}\sin^2 2\pi t - 1\biggr) \\ &\quad \times \biggl(z_2 + \frac{1}{4\pi} - \frac{1}{4\pi}\cos 2\pi t - \frac{1}{16\pi^2}\bigl(z_1^2 - 1\bigr)\sin 2\pi t\biggr) \\ &\quad - z_1 + \frac{1}{8\pi^2}\sin 2\pi t\biggr]\,\mathrm{d}t \\ &= \frac{1}{2}\int_0^1 \biggl[\frac{1}{64\pi^4}\bigl(z_1^2 - 1\bigr)\sin^2 2\pi t - z_1\biggr]\,\mathrm{d}t \\ &= \frac{1}{128\pi^4}\bigl(z_1^2 - 1\bigr) - 2z_1 = 0,\end{aligned}$$

has the solution

$$z_2 = -\frac{1}{4\pi}, \qquad z_1 = 128\pi^4 \pm \sqrt{\bigl(128\pi^4\bigr)^2 + 1},$$

because z_1 satisfies the equality $z_1^2 - 256\pi^4 z_1 - 1 = 0$.

Taking into account the fact that $\operatorname{col}(z_1, z_2)$ must belong to domain (3.141), we obtain that, in the second approximation, the initial value of the 1-periodic solution of (3.131), (3.139) has the form

$$\operatorname{col}(z_1, z_2) = \operatorname{col}\biggl(128\pi^4 - \sqrt{\bigl(128\pi^4\bigr)^2 + 1}, -\frac{1}{4\pi}\biggr).$$

Again we note that Corollary 5.6 from [81, p. 195] cannot be applied to Van der Pol's system (3.131), (3.139) in domain (3.140), because the inequalities

$$-1 + \frac{1}{2}\sin\omega t > 0, \qquad 1 + \frac{1}{2}\sin\omega t < 0$$

from the assumptions of the corollary mentioned do not hold for all $t \in [0, T]$.

The following theorem gives a condition necessary for $G \subset D_{\frac{T}{2}M}$ to contain the initial value z^* of a T-periodic solution $x^*(t) = x^*(t, 0, z^*)$ of system (3.3).

THEOREM 3.36. *Suppose that the T-periodic boundary value problem* (3.3), (3.4) *satisfies conditions* (3.5), (3.6), (3.61), *and* (3.62). *Then in order that a subset $G \subset D_{\frac{T}{2}M}$ contain the initial value $z^* = x^*(0)$ of the T-periodic solution $x = x^*(t)$ of* (3.1) *at $t = 0$, it is necessary that, for arbitrary $w \in G$ and integer m, the following inequality be satisfied*:

$$\begin{aligned}\Delta_m(w) &\leqslant \sup_{z\in G} K\biggl[I + \frac{10}{27}TK(I-Q)^{-1}\biggr]|z - w| \\ &\quad + \frac{10}{27}TKQ^m(I-Q)^{-1}M, \end{aligned}\tag{3.142}$$

where Δ_m *is the* m*-th approximation* (3.91) *of the determining function* (3.85) *and* Q *is the matrix given by* (3.45).

PROOF. Assume that $z = z^*$ is a solution of the determining equation (3.85), i.e., $\Delta(z^*) = 0$. Consequently, according to Theorem 3.21, $z^* = x^*(0)$ is the initial value at $t = 0$ of the periodic solution $x^*(t) = x^*(t, z^*)$, $t \in [0, T]$, where $x^*(\cdot, z)$ is the limit function of the sequence (3.29).

Let apply estimate (3.86) from Theorem 3.23 with $z = z^*$, $y = w$. Then it follows from (3.86) that

$$\left|\Delta(w)\right| = K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]|z^* - w|. \tag{3.143}$$

In view of inequality (3.92) of Lemma 3.26, we obtain

$$\begin{aligned}
&\left|\Delta(w) - \Delta_m(w)\right| \leqslant \frac{10}{27}TKQ^m(I - Q)^{-1}M,\\
&\left|\Delta_m(w)\right| \leqslant \left|\Delta(w)\right| + \frac{10}{27}TKQ^m(I - Q)^{-1}M.
\end{aligned} \tag{3.144}$$

Combining (3.144) with (3.143), we prove the validity of inequality (3.142):

$$\begin{aligned}
\left|\Delta_m(w)\right| &\leqslant K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]|z^* - w| + \frac{10}{27}TKQ^m(I - Q)^{-1}M\\
&\leqslant \sup_{z \in G} K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]|z - w| + \frac{10}{27}TKQ^m(I - Q)^{-1}M.
\end{aligned}$$

The theorem is proved. □

REMARK 3.37. According to Theorem 3.36, we can indicate an algorithm for approximate determination of the initial value z^* of a solution of the T-periodic boundary value problem (3.3), (3.4). For this purpose, we represent the subset $D_{\frac{T}{2}M}$ defined in (3.8) as the union of finitely many subsets Ω_i, i.e.,

$$D_{\frac{T}{2}M} = \bigcup_{i=1}^{N} \Omega_i.$$

In every Ω_i, we choose an arbitrary point $w^i \in \Omega_i$ and, for a certain m, we compute the value of the mth successive approximation $x_m(t, w^i)$ according to formula (3.29) and the value of the corresponding approximate determining function, $\Delta_m(w^i)$ according to (3.91). Then, by using (3.142), we exclude the subsets Ω_i for an arbitrary point w^i of which the inequality inverse to (3.142), i.e.,

$$\left|\Delta_m(w^i)\right| > K\left[I + \frac{10}{27}TK(I - Q)^{-1}\right]\sup_{z \in G}|z - w^i| + \frac{10}{27}TKQ^m(I - Q)^{-1}M$$

holds. The reason for this is provided by Theorem 3.36, which guarantees that such subsets cannot contain initial values of solution of the periodic boundary value problem (3.3), (3.4).

The remaining subsets $\Omega_{i_1}, \Omega_{i_2}, \dots, \Omega_{i_s}$ form a certain set $\Omega_{m,N}$,

$$\Omega_{m,N} := \bigcup_{\nu=1}^{s} \Omega_{i_\nu},$$

such that only through its points the T-periodic solutions of system (3.1) can pass. When N and m tend to ∞, the set $\Omega_{m,N}$ "tends" (see Problem 10.1) to the set Ω^* of *all* the initial values of the T-periodic solutions with values in $D_{\frac{T}{2}M}$. Every point u from $\Omega_{m,N}$ can be regarded as an approximate value of an exact initial value $z^* \in D^*$. In this case, obviously,

$$\left|u - z^*\right| \leqslant \sup_{u \in \Omega_{m,N}} |u - z|, \tag{3.145}$$

and the function $x_m(\cdot, u)$ given by the recurrence formula (3.29) can naturally be taken as an approximate T-periodic solution of the T-periodic boundary value problem (3.3), (3.4).

Let us estimate the absolute error of the approximate T-periodic solution, i.e., the deviation of the limit function $x^*(\cdot, z^*)$ from the approximate T-periodic solution $x_m(\cdot, u)$.

THEOREM 3.38. *Let conditions* (3.5), (3.6), (3.61), *and* (3.62) *be satisfied for the periodic boundary value problem* (3.3), (3.4); z^* *be a solution of the exact determining equation* (3.85), *and* u *an arbitrary point from the subset* $\Omega_{m,N}$ *satisfying condition* (3.145). *Then for the deviation of the exact* T*-periodic solution* $x^*(\cdot, z^*)$ *from its approximation* $x_m(\cdot, u)$ *given by* (3.29), *the following inequality is true*:

$$\begin{aligned}\left|x^*(t, z^*) - x_m(t, u)\right| &\leqslant \bar{\alpha}_{1,T}(t) Q^m (I - Q)^{-1} M \\ &\quad + \left(I + \bar{\alpha}_{1,T}(t) K (I - Q)^{-1}\right) \sup_{z \in \Omega_{m,N}} |z - u|,\end{aligned} \tag{3.146}$$

where Q *is given by* (3.45) *and* $\bar{\alpha}_{1,T}$ *is the function* (3.37).

PROOF. Let us use the obvious inequality

$$\begin{aligned}\left|x^*(t, z^*) - x_m(t, u)\right| &\leqslant \left|x^*(t, z^*) - x_m(t, z^*)\right| \\ &\quad + \left|x_m(t, z^*) - x_m(t, u)\right|.\end{aligned} \tag{3.147}$$

We estimate the first term on the right-hand side of (3.147) by using (3.44):

$$\left|x^*(t, z^*) - x_m(t, z^*)\right| \leqslant \bar{\alpha}_{1,T}(t) Q^m (I - Q)^{-1} M, \tag{3.148}$$

whereas the second term is estimated according to (3.83):

$$\begin{aligned}
&\bigl|x_m(t,z^*)-x_m(t,u)\bigr|\\
&\quad\leqslant\bigl[I+\alpha_{1,T}(t)K+\alpha_{2,T}(t)K^2+\cdots+\alpha_{m,T}(t)K^m\bigr]|z^*-u|\\
&\quad\leqslant\left[I+\bar\alpha_{1,T}(t)\sum_{i=0}^{m-1}K\left(\frac{3T}{10}K\right)^i\right]|z^*-u|\\
&\quad\leqslant\bigl[I+\bar\alpha_{1,T}(t)K(I-Q)^{-1}\bigr]|z^*-u|.
\end{aligned}\tag{3.149}$$

Consequently, in view of (3.145), (3.146), (3.149) inequality (3.147) yields

$$\begin{aligned}
\bigl|x^*(t,z^*)-x_m(t,u)\bigr|\leqslant{}&\bar\alpha_{1,T}(t)Q^m(I-Q)^{-1}M\\
&+\bigl[I+\bar\alpha_{1,T}(t)K(I-Q)^{-1}\bigr]|z^*-u|,
\end{aligned}$$

or

$$\begin{aligned}
\bigl|x^*(t,z^*)-x_m(t,u)\bigr|\leqslant{}&\bar\alpha_{1,T}(t)Q^m(I-Q)^{-1}M\\
&+\bigl[I+\bar\alpha_{1,T}(t)K(I-Q)^{-1}\bigr]\sup_{z\in\Omega_{m,N}}|z-u|,
\end{aligned}\tag{3.150}$$

i.e., estimate (3.146) is true. □

4. Successive approximations for autonomous systems

In this section, we present some results concerning the application of the successive approximation techniques to autonomous systems of differential equations. Consider the case where the right-hand side of system (3.1) is independent of t:

$$x'(t)=f\bigl(x(t)\bigr),\quad -\infty<t<\infty.\tag{4.1}$$

Here, $f:D\to\mathbb{R}^n$ is a continuous function and $D\subset\mathbb{R}^n$ is a closed bounded set. We are interested in T-periodic solutions of system (4.1).

Unlike the non-autonomous systems, where the period T of the solution is known, in the autonomous case, besides the initial values of the periodic solution of (4.1), one should also find its period. Moreover, the T-periodic solution $x=x^*(t)$ of autonomous system (4.1) is not isolated in the extended phase space, which means that every member of the one-parameter family of functions

$$[0,T]\ni t\longmapsto x^*(t+\varphi),\quad \varphi\in[0,T],\tag{4.2}$$

is also a T-periodic solution. The latter circumstance, in particular, excludes every possibility of studying this problem via topological degree methods.

In the autonomous case (4.1), the direct application of the successive approximation techniques with the main equations (3.29), (3.41), (3.85), described above for the non-autonomous case, yields

$$\begin{aligned} x_m(t,z) &= z + \int_0^t f\big(x_{m-1}(s,z)\big)\,\mathrm{d}s - \frac{t}{T}\int_0^T f\big(x_{m-1}(s,z)\big)\,\mathrm{d}s, \\ \Delta(z) &= \frac{1}{T}\int_0^T f\big(x_{m-1}(t,z)\big)\,\mathrm{d}t, \end{aligned} \tag{4.3}$$

which implies that

$$x_m(t,z) = x_m^*(t,z) = z, \qquad \Delta(z) \equiv f(z) = 0.$$

Therefore, the successive approximation scheme determined by (4.3) “detects” only the stationary (i.e., constant) periodic solutions of the autonomous system (4.1). In order to find the non-constant T-periodic solutions of (4.1), the following modification can be used [90,91].

The change of variables

$$t = \frac{T}{\tilde{T}}\theta \tag{4.4}$$

allows one to study the periodic solution of (4.1) with a certain fixed period $\tilde{T} \in (0, +\infty)$, i.e., to investigate the following parametrised $\tilde{T}$-periodic boundary value problem

$$x'(\theta) = \mu f\big(x(\theta)\big), \tag{4.5}$$

$$x(0) = x(\tilde{T}), \tag{4.6}$$

where $x : [0, \tilde{T}] \to D$ and $\mu = T\tilde{T}^{-1}$.

Let us suppose that, for some fixed

$$\mu = \mu_0 > 0, \tag{4.7}$$

the $\tilde{T}$-periodic boundary value problem (4.5), (4.6) has a non-constant solution $x = \bar{x}(\theta)$. As in (4.2), the members of the one-parameter family

$$[0, T] \ni \theta \longmapsto \bar{x}(\theta + \varphi), \quad \varphi \in [0, \tilde{T}] \tag{4.8}$$

are also $\tilde{T}$-periodic solutions. Due to the periodicity and continuity of functions (4.8), the components of the solution

$$\bar{x}(\theta) = \mathrm{col}\big(\bar{x}_1(\theta), \bar{x}_2(\theta), \ldots, \bar{x}_n(\theta)\big) \tag{4.9}$$

assume their extremal values over the interval $[0, \tilde{T}]$ at some points θ_{i1}, θ_{i2}:

$$\max_{\theta\in[0,\tilde{T}]} \bar{x}_i(\theta) = \bar{x}_i(\theta_{i1}), \qquad \min_{\theta\in[0,\tilde{T}]} \bar{x}_i(\theta) = \bar{x}_i(\theta_{i2})$$

for $i = 1, 2, \dots, n$.

Since all the periodic solutions (4.8) represent one and the same trajectory, it follows that for all $i = 1, 2, \dots, n$

$$\max_{\theta\in[0,\tilde{T}]} \bar{x}_i(\theta+\varphi) = \bar{x}_i(\theta_{i1}), \qquad \min_{\theta\in[0,\tilde{T}]} \bar{x}_i(\theta+\varphi) = \bar{x}_i(\theta_{i2}).$$

Therefore, without loss of generality, having replaced x^0 by $x^0(\cdot+\varphi)$ with a suitable φ, we can assume in the subsequent consideration that a certain fixed, say jth, component of function (4.8) takes its extremal value over $[0, \tilde{T}]$ at the point $\theta = 0$:

$$\max_{\theta\in[0,\tilde{T}]} \bar{x}_j(\theta) = \bar{x}_j(0) \quad \text{or} \quad \min_{\theta\in[0,\tilde{T}]} \bar{x}_j(\theta) = \bar{x}_j(0).$$

Thus, for the boundary value problem (4.5), (4.6) to be solvable it is necessary that

$$\frac{\mathrm{d}\bar{x}_j}{\mathrm{d}\theta}(0) = 0,$$

i.e., the initial value $x_0 = \bar{x}(0)$ of the solution should lie on the hypersurface

$$\Gamma_j = \left\{x \in \mathbb{R}^n \mid f_j(x) = 0\right\},$$

where $f = \mathrm{col}(f_1, f_2, \dots, f_n)$.

Let us suppose that, in D, the equation

$$f_j(x) = 0 \tag{4.10}$$

has an $(n-1)$-parametric family of solutions

$$x = x_0(c), \tag{4.11}$$

where $c = \mathrm{col}(c_1, c_2, \dots, c_{n-1}) \in \mathbb{R}^{n-1}$ is a vector parameter. Therefore, according to our approach, the $\tilde{T}$-periodic solution of the boundary value problem (4.5), (4.6) will be determined on the set of solutions of the Cauchy problem of (4.5), (4.12):

$$x(0) = x_0(c). \tag{4.12}$$

4.1. *Non-linear substitution of variables*

The next step is to change the variable x according to the formula

$$x(\theta) = \Phi\big(\theta, y(\theta)\big), \quad \theta = \frac{\tilde{T}}{T}t,\ t \in [0, T], \tag{4.13}$$

which allows us to transform the autonomous system (4.5) into a non-autonomous one and then study problem (4.5), (4.6) near the hypothetical solution. The function

$$\Phi : \mathbb{R} \times \mathcal{B} \to D, \tag{4.14}$$

where $\mathcal{B} \subset \mathbb{R}^n$ is a bounded set, is $\tilde{T}$-periodic in the first variable and satisfies all conditions which are usually imposed on the change of variables, namely, $\Phi(\theta, y)$ is continuously differentiable with respect to the variables θ and y and satisfies the condition

$$\det\left[\frac{\partial\Phi(\theta, y)}{\partial y}\right] \neq 0, \quad (\theta, y) \in [0, \tilde{T}] \times \mathcal{B}. \tag{4.15}$$

As a result of the transformation of variables (4.13), Eq. (4.5) takes the form

$$y'(\theta) = F\big(\theta, y(\theta), \mu\big), \tag{4.16}$$

where

$$F(\theta, y, \mu) = \left[\frac{\partial\Phi(\theta, y)}{\partial y}\right]^{-1}\left[\mu f\big(\Phi(\theta, y)\big) - \frac{\partial\Phi(\theta, y)}{\partial\theta}\right]. \tag{4.17}$$

After the coordinate transformation (4.13), at $\theta = 0$, the hypersurface (4.9) turns into the hypersurface

$$\bar{\Gamma}_j = \big\{y_0(c) \mid c \in \mathbb{R}^n\big\},$$

where $y = y_0(c)$ is the solution of the equation

$$x_0(c) = \Phi(0, y). \tag{4.18}$$

This means that the initial value $x = x_0(c)$ that may determine a $\tilde{T}$-periodic solution of (4.12), turns into the initial value

$$y = y_0(c), \tag{4.19}$$

of the $\tilde{T}$-periodic solution of Eq. (4.16).

In order to use the successive approximation techniques with the main equations (3.29), (3.41), (3.85) for system (4.16), it will be assumed that for the values of parameter

$$\mu = \frac{T}{\tilde{T}} \tag{4.20}$$

from some interval

$$J = [\mu_1, \mu_2], \tag{4.21}$$

and for $(\theta, y) \in [0, \tilde{T}] \times \mathcal{B}$, conditions analogous to (3.5)–(3.7), and (3.8) are satisfied for system (4.16). More precisely, we suppose that:

(1) In the domain

$$G = [0, \tilde{T}] \times \mathcal{B} \times J, \tag{4.22}$$

the function F is bounded by the vector $M \in \mathbb{R}^n_+$ in the sense that

$$\frac{1}{2}\left[\max_{(\theta,y,\mu)\in G} F(\theta, y, \mu) - \min_{(\theta,y,\mu)\in G} F(\theta, y, \mu)\right] \leqslant M, \tag{4.23}$$

and, furthermore, satisfies the Lipschitz condition in the second argument with some matrix $K = \{K_{ij}\}_{i,j=1}^n \in \mathrm{GL}_n(\mathbb{R})$:

$$\bigl|F(\theta, u, \mu) - F(\theta, v, \mu)\bigr| \leqslant K|u - v| \tag{4.24}$$

for all $\theta \in [0, \tilde{T}]$, $u, v \in \mathcal{B}$, $\mu \in J$.

(2) The maximal eigenvalue $r(K)$ of the matrix K is such that

$$r(K) < \frac{10}{3\tilde{T}}. \tag{4.25}$$

(3) The set

$$\mathcal{B}_{\frac{\tilde{T}}{2}M} = \left\{ y \in \mathbb{R}^n \;\middle|\; B\left(y, \frac{\tilde{T}}{2}M\right) \subset \mathcal{B} \right\},$$

determined by the non-negative vector M in (4.23), is non-empty:

$$\mathcal{B}_{\frac{\tilde{T}}{2}M} \neq \varnothing. \tag{4.26}$$

REMARK 4.1. Similarly to (3.11), the following estimate holds:

$$\max_{(\theta,y,\mu)\in G} F(\theta, y, \mu) - \min_{(\theta,y,\mu)\in G} F(\theta, y, \mu) \leqslant 2 \max (\theta, y, \mu) \in G\bigl|F(\theta, y, \mu)\bigr|.$$

We note also that if the relations (4.25) and (4.26) are true for some $\mu = \mu_0$, then they also hold for all $\mu > \mu_0$.

In connection with Eq. (4.16), we introduce the sequence of $\tilde{T}$-periodic functions $\{y_m(\theta, c, \mu)\}$ defined by the recurrence relation

$$y_m(\theta, c, \mu) = y_0(c) + \int_0^\theta \Big[F\big(s, y_{m-1}(s, c, \mu), \mu\big) - \frac{1}{\tilde{T}} \int_0^{\tilde{T}} F\big(\tau, y_{m-1}(\tau, c, \mu), \mu\big)\, \mathrm{d}\tau \Big] \mathrm{d}s, \quad m = 1, 2, \ldots. \tag{4.27}$$

These functions depend on the n real parameters

$$c = \operatorname{col}(c_1, c_2, \ldots, c_{n-1}) \in \mathbb{R}^{n-1}, \quad \mu \in J.$$

We define the starting member of sequence (4.27) as

$$y_0(\theta, c, \mu) = y_0(c)$$

with c such that $y_0(c) \in \mathcal{B}_{\frac{\tilde{T}}{2}M}$. The set of all such c from $\mathbb{R}^{n-1}$ will be denoted by H_f. Recall that $y_0(c)$ is given by formulae (4.18) and (4.19)

The following statement establishes the convergence of the sequence (4.27).

THEOREM 4.2. *Let the function f in the autonomous system* (4.5) *and the coordinate transformation* (4.13) *be such that for the non-autonomous $\tilde{T}$-periodic system* (4.16) *with F given by* (4.17)*, conditions* (4.23)–(4.26) *hold. Then, for arbitrary values of the parameters*

$$c \in H_f, \qquad \mu \in J,$$

the following assertions are true:

(i) *The sequence $\{y_m(\theta, c, \mu)\}$ of $\tilde{T}$-periodic functions* (4.27) *is uniformly convergent,*

$$\lim_{m \to \infty} y_m(\theta, c, \mu) = y^*(\theta, c, \mu) \tag{4.28}$$

with respect to

$$(\theta, c, \mu) \in (-\infty, \infty) \times H_f \times J;$$

(ii) *The limit function $y^*(\theta, c, \mu)$ is the unique $\tilde{T}$-periodic solution of the integral equation*

$$y(\theta) = y_0(c) + \int_0^\theta F\big(s, y(s), \mu\big)\, \mathrm{d}s - \frac{\theta}{\tilde{T}} \int_0^{\tilde{T}} F\big(s, y(s), \mu\big)\, \mathrm{d}s, \tag{4.29}$$

with values in the domain $\mathcal{B}$; *alternatively, it is the unique* $\tilde{T}$*-periodic solution of the Cauchy problem for the integro-differential equation*

$$\frac{\partial y(\theta, c, \mu)}{\partial \theta} = F\bigl(\theta, y(s, c, \mu), \mu\bigr) - \Delta(c, \mu), \tag{4.30}$$

$$y(0, c, \mu) = y_0(c), \tag{4.31}$$

where

$$\Delta(c, \mu) = \frac{1}{\tilde{T}} \int_0^{\tilde{T}} F\bigl(\theta, y^*(\theta, c, \mu), \mu\bigr)\, \mathrm{d}\theta; \tag{4.32}$$

(iii) *The estimate*

$$\bigl|y^*(\theta, c, \mu) - y_m(\theta, c, \mu)\bigr| \leqslant \bar{\alpha}_{1,\tilde{T}}(\theta)\left(\frac{3\tilde{T}}{10}K\right)^m \left(I - \frac{3\tilde{T}}{10}K\right)^{-1} M \tag{4.33}$$

holds for an arbitrary $\theta \in (-\infty, \infty)$, *where the function* $\bar{\alpha}_{1,\tilde{T}}$ *is given by formulae* (3.37), (3.31).

PROOF. It is easy to see that Theorem 4.2 is rather similar to Theorem 3.17 and, hence, its proof is omitted. □

Let us establish a general condition necessary and sufficient for the existence of a T-periodic solution of the autonomous system (4.1).

THEOREM 4.3. *Let us assume that, for the autonomous system* (4.5), *for the coordinate transformation* (4.13), *and for the non-autonomous* $\tilde{T}$*-periodic system* (4.16), (4.17), *conditions* (4.23)–(4.26) *hold. Then the solution* $y = y(\theta, 0, y_0(c^*), \mu^*)$ *of the Cauchy problem*

$$y'(\theta) = F\bigl(\theta, y(\theta), \mu^*\bigr), \tag{4.34}$$

$$y(0) = y_0(c^*), \tag{4.35}$$

where $c \in H_f$ *and, hence* $y_0(c^*) \in \mathcal{B}_{\frac{T}{2}M}$, *is a* $\tilde{T}$*-periodic solution of* (4.34) *if and only if* $(c^*, \mu^*) \in H_f \times J$ *is a zero of the determining function* (4.32), *i.e.*

$$\Delta(c^*, \mu^*) := \frac{1}{\tilde{T}} \int_0^{\tilde{T}} F\bigl(\theta, y^*(\theta, c^*, \mu^*), \mu^*\bigr)\, \mathrm{d}\theta = 0, \tag{4.36}$$

and in this case $y = y(\theta, 0, y_0(c^*), \mu^*) = y^*(\theta, c^*, \mu^*)$, *where*

$$y^*(\theta, c^*, \mu^*) = \lim_{m \to \infty} y_m(\theta, c^*, \mu^*). \tag{4.37}$$

According to the change of variables (4.13), *the values* (c^*, μ^*) *and the* $\tilde{T}$*-periodic solution* $y^*(\theta, c^*, \mu^*)$ *of the non-autonomous system* (4.34) *determine the* T*-periodic solution of the autonomous system* (4.1)

$$x = x^*(t) = \Phi\left(\frac{t}{\mu^*}, y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right)\right) \tag{4.38}$$

and its period

$$T^* = \mu^* \tilde{T}. \tag{4.39}$$

PROOF. The sufficiency of condition (4.36) follows immediately from the fact that the function $y^*(\theta, c, \mu)$ is a $\tilde{T}$-periodic solution of the initial value problem (4.30), (4.31). It is obvious that if (4.36) holds, then this condition is sufficient for (4.37) to be a $\tilde{T}$-periodic solution of (4.16) and of the initial value problem (4.34), (4.35). Our change of variables,

$$\frac{t}{\mu} = \theta, \quad \tilde{T}\mu = T, \quad x = \Phi(\theta, y),$$

yields (4.38), (4.39).

The necessity of condition (4.36) can be established by analogy with the proof of Theorem 3.21. □

Now we establish some properties of the limit function (4.28) and the determining function (4.32).

THEOREM 4.4. *Let us suppose that, in domain* (4.22), *conditions* (4.23), (4.25), (4.26) *hold and, moreover, there exist some non-negative matrix* $K = \{K_{ij}\}_{i,j=1}^n \in \mathrm{GL}_n(\mathbb{R})$ *and vector* $\tilde{M} = \{\tilde{M}_i\}_{i=1}^n \in \mathbb{R}_+^n$ *such that the function* $(\theta, y, \mu) \mapsto F(\theta, y, \mu)$ *satisfies the following Lipschitz condition in* y *and* μ:

$$\left|F(\theta, u, \mu) - F(\theta, v, \xi)\right| \leqslant K|u - v| + |\mu - \xi|\tilde{M}. \tag{4.40}$$

Then the function $y^*(\theta, c, \mu)$ *given by* (4.28), (4.27) *and the determining function* $\Delta(c, \mu)$ *of the form* (4.32) *are Lipschitzian in the sense that, for all*

$$\{c, a\} \subset H_f, \quad \{\mu, \xi\} \subset J, \quad \theta \in [0, \tilde{T}], \tag{4.41}$$

we have

$$\begin{aligned} &\left|y^*(\theta, c, \mu) - y^*(\theta, a, \xi)\right| \\ &\quad \leqslant \left[I + \bar{\alpha}_{1,\tilde{T}}(\theta) K \left(I - \frac{3\tilde{T}}{10} K\right)^{-1}\right] \left|y_0(c) - y_0(a)\right| \\ &\qquad + \left[I + \left(I - \frac{3\tilde{T}}{10} K\right)^{-1}\right] \bar{\alpha}_{1,\tilde{T}}(\theta) |\mu - \xi| \tilde{M}, \end{aligned} \tag{4.42}$$

and the relations

$$\left|\Delta(c,\mu)-\Delta(a,\xi)\right| \leqslant K\left[I+\frac{10\tilde{T}}{27}K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\left|y_0(c)-y_0(a)\right| \\ + K\left[I+\frac{10\tilde{T}}{27}K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]|\mu-\xi|\tilde{M}, \tag{4.43}$$

$$\left|\Delta(c,\mu)-\Delta_m(c,\mu)\right| \leqslant \frac{10\tilde{T}}{27}K\left(\frac{3\tilde{T}}{10}K\right)^m\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}M, \tag{4.44}$$

hold true, where

$$\Delta_m(c,\mu) := \frac{1}{\tilde{T}}\int_0^{\tilde{T}} F\bigl(\theta, y_m(\theta,c,\mu),\mu\bigr)\,\mathrm{d}\theta \tag{4.45}$$

is the m*th approximation to function* (4.32) *and* $y_0(c)$, *and* $y_0(a)$ *are determined by* (4.11), (4.18), *and* (4.19).

PROOF. The uniform convergence of sequence (4.27) in domain (4.41) guarantees the continuity of the function $y^*(\theta,c,\mu)$ with respect to all the variables. Equality (4.32) ensures the continuity of the function $\Delta(c,\mu)$ in domain (4.41) and the fulfilment of the inequality

$$\left|\Delta(c,\mu)\right| \leqslant \max_{(\theta,y,\mu)\in[0,\tilde{T}]\times\mathcal{B}\times J}\left|F(\theta,y,\mu)\right|.$$

It follows directly from (4.27) that

$$\begin{aligned} & y_1(\theta,c,\mu)-y_1(\theta,a,\xi) \\ &\quad = y_0(c)-y_0(a)+\int_0^{\theta}\bigl[F\bigl(s,y_0(c),\mu\bigr)-F\bigl(s,y_0(a),\xi\bigr)\bigr]\,\mathrm{d}s \\ &\qquad - \frac{\theta}{\tilde{T}}\int_0^{\tilde{T}}\bigl[F\bigl(s,y_0(c),\mu\bigr)-F\bigl(s,y_0(a),\xi\bigr)\bigr]\,\mathrm{d}s \\ &\quad = y_0(c)-y_0(a)+\left(1-\frac{\theta}{\tilde{T}}\right)\int_0^{\theta}\bigl[F\bigl(s,y_0(c),\mu\bigr)-F\bigl(s,y_0(a),\xi\bigr)\bigr]\,\mathrm{d}s \\ &\qquad - \frac{\theta}{\tilde{T}}\int_{\theta}^{\tilde{T}}\bigl[F\bigl(s,y_0(c),\mu\bigr)-F\bigl(s,y_0(a),\xi\bigr)\bigr]\,\mathrm{d}s. \end{aligned} \tag{4.46}$$

Due to the Lipschitz condition (4.40) and equality (3.33) of Lemma 3.16, from (4.46) we get

$$\begin{aligned} & \left|y_1(\theta,c,\mu)-y_1(\theta,a,\xi)\right| \\ &\quad \leqslant \left|y_0(c)-y_0(a)\right|+\left(1-\frac{\theta}{\tilde{T}}\right)\int_0^{\theta}\bigl[K\left|y_0(c)-y_0(a)\right|+|\mu-\xi|\tilde{M}\bigr]\,\mathrm{d}s \end{aligned}$$

$$
\begin{aligned}
&+\frac{\theta}{\tilde{T}}\int_{\theta}^{\tilde{T}}\left[K\left|y_0(c)-y_0(a)\right|+|\mu-\xi|\tilde{M}\right]\mathrm{d}s\\
&=\left[I+\alpha_{1,\tilde{T}}(\theta)K\right]\left|y_0(c)-y_0(a)\right|+\alpha_{1,\tilde{T}}(\theta)|\mu-\xi|\tilde{M}.
\end{aligned}
\tag{4.47}
$$

Similarly, taking into account (4.47), we obtain

$$
\begin{aligned}
&\left|y_2(\theta,c,\mu)-y_2(\theta,a,\xi)\right|\\
&\quad\leqslant\left|y_0(c)-y_0(a)\right|\\
&\qquad+\left(1-\frac{\theta}{\tilde{T}}\right)\int_0^{\theta}\left[K\left|y_1(s,c,\mu)-y_1(s,a,\xi)\right|+|\mu-\xi|\tilde{M}\right]\mathrm{d}s\\
&\qquad+\frac{\theta}{\tilde{T}}\int_{\theta}^{\tilde{T}}\left[K\left|y_1(s,c,\mu)-y_1(s,a,\xi)\right|+|\mu-\xi|\tilde{M}\right]\mathrm{d}s\\
&\quad=\left[I+\alpha_{1,\tilde{T}}(\theta)K+\alpha_{2,\tilde{T}}(\theta)K^2\right]\left|y_0(c)-y_0(a)\right|\\
&\qquad+\left[\alpha_{1,\tilde{T}}(\theta)K+\alpha_{2,\tilde{T}}(\theta)K^2\right]|\mu-\xi|\tilde{M}.
\end{aligned}
$$

Proceeding analogously and arguing by induction, we finally conclude that

$$
\begin{aligned}
&\left|y_m(\theta,c,\mu)-y_m(\theta,a,\xi)\right|\\
&\quad\leqslant\left[I+\alpha_{1,\tilde{T}}(\theta)K+\alpha_{2,\tilde{T}}(\theta)K^2+\cdots+\alpha_{m,\tilde{T}}(\theta)K^m\right]\left|y_0(c)-y_0(a)\right|\\
&\qquad+\left[\alpha_{1,\tilde{T}}(\theta)K+\alpha_{2,\tilde{T}}(\theta)K^2+\cdots+\alpha_{m,\tilde{T}}(\theta)K^{m-1}\right]|\mu-\xi|\tilde{M},
\end{aligned}
\tag{4.48}
$$

where $\alpha_{m,\tilde{T}}$ is the function given by (3.33), i.e.,

$$
\alpha_{m+1,\tilde{T}}(\theta)=\left(1-\frac{\theta}{\tilde{T}}\right)\int_0^{\theta}\alpha_{m,\tilde{T}}(s)\,\mathrm{d}s+\frac{\theta}{\tilde{T}}\int_{\theta}^{\tilde{T}}\alpha_{m,\tilde{T}}(s)\,\mathrm{d}s.
\tag{4.49}
$$

In view of inequality (4.25) the maximal eigenvalue of the matrix $\frac{3\tilde{T}}{10}K$ is less than one and, therefore, by letting $m\to\infty$ in (4.48) and using estimates (3.36) of Lemma 3.16 and the inequality

$$
\alpha_{1,\tilde{T}}(\theta)\leqslant\frac{10}{9}\alpha_{1,\tilde{T}}(\theta)=\bar{\alpha}_{1,\tilde{T}}(t),
$$

we get

$$
\begin{aligned}
\left|y^*(\theta,c,\mu)-y^*(\theta,a,\xi)\right|\leqslant&\left[I+\bar{\alpha}_{1,\tilde{T}}(\theta)K\sum_{i=0}^{\infty}\left(\frac{3\tilde{T}}{10}K\right)^i\right]\left|y_0(c)-y_0(a)\right|\\
&+\left[I+\sum_{i=0}^{\infty}\left(\frac{3\tilde{T}}{10}K\right)^i\right]\bar{\alpha}_{1,\tilde{T}}(\theta)|\mu-\xi|\tilde{M}.
\end{aligned}
$$

Thus, we have

$$\begin{aligned}\big|y^*(\theta,c,\mu)-y^*(\theta,a,\xi)\big| \leqslant{}& \left[I+\bar{\alpha}_{1,\tilde{T}}(\theta)K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\big|y_0(c)-y_0(a)\big|\\ &+\left[I+\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\bar{\alpha}_{1,\tilde{T}}(\theta)|\mu-\xi|\tilde{M}.\end{aligned} \tag{4.50}$$

Equality (4.32), together with the Lipschitz condition (4.24), yields

$$\begin{aligned}\big|\Delta(c,\mu)-\Delta(a,\mu)\big| &= \frac{1}{\tilde{T}}\left|\int_0^{\tilde{T}}\big[F\big(\theta,y^*(\theta,c,\mu),\mu\big)-F\big(\theta,y^*(\theta,a,\xi),\xi\big)\big]\,\mathrm{d}\theta\right|\\ &\leqslant \frac{1}{\tilde{T}}K\int_0^{\tilde{T}}\big|y^*(\theta,c,\mu)-y^*((\theta,a,\xi),\xi)\big|\,\mathrm{d}\theta.\end{aligned} \tag{4.51}$$

Substituting (4.42) into (4.51) and taking into account the equality

$$\int_0^{\tilde{T}}\bar{\alpha}_{1,T}(\theta)\,\mathrm{d}\theta=\frac{10}{9}\int_0^{\tilde{T}}2\theta\left(1-\frac{\theta}{\tilde{T}}\right)\mathrm{d}\theta=\frac{10}{27}\tilde{T}^2, \tag{4.52}$$

we get

$$\begin{aligned}&\big|\Delta(c,\mu)-\Delta(a,\mu)\big|\\ &\quad\leqslant\frac{1}{\tilde{T}}K\int_0^{\tilde{T}}\left[I+\bar{\alpha}_{1,\tilde{T}}(\theta)K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\mathrm{d}\theta\big|y_0(c)-y_0(a)\big|\\ &\qquad+\frac{1}{\tilde{T}}K\int_0^{\tilde{T}}\left[I+\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\bar{\alpha}_{1,\tilde{T}}(\theta)|\mu-\xi|\tilde{M}\\ &\quad\leqslant K\left[I+\frac{10\tilde{T}}{27}K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\big|y_0(c)-y_0(a)\big|\\ &\qquad+K\left[I+\frac{10\tilde{T}}{27}K\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]|\mu-\xi|\tilde{M}.\end{aligned}$$

In view of estimate (4.33), it follows directly from (4.32), (4.45), and (4.52) that

$$\begin{aligned}\big|\Delta(c,\mu)-\Delta_m(c,\mu)\big| = \bigg|\frac{1}{\tilde{T}}\int_0^{\tilde{T}}&\big[F\big(\theta,y^*(\theta,c,\mu),\mu\big)\\ &-F\big(\theta,y_m(\theta,c,\mu),\mu\big)\big]\,\mathrm{d}\theta\bigg|\end{aligned}$$

$$\leqslant \frac{1}{\tilde{T}} K \int_0^{\tilde{T}} \left| y^*(\theta, c, \mu) - y_m(\theta, c, \mu) \right| \mathrm{d}\theta$$
$$\leqslant \frac{1}{\tilde{T}} K \left(\frac{3\tilde{T}}{10} K \right)^m \left(I - \frac{3\tilde{T}}{10} K \right)^{-1} M \int_0^{\tilde{T}} \overline{\alpha}_{1,\tilde{T}}(\theta) \, \mathrm{d}\theta$$
$$= \frac{10\tilde{T}}{27} K \left(\frac{3\tilde{T}}{10} K \right)^m \left(I - \frac{3\tilde{T}}{10} K \right)^{-1} M.$$

The theorem is proved. □

Theorem 4.3 provides the following numerical-analytic algorithm for finding a T-periodic solution of the autonomous system (4.1) approximately and for the determination of its unknown period T.

(1) We choose a $\tilde{T}$-periodic coordinate transformation (4.13) with properties (4.14) and (4.15) such that the transformed equation satisfies conditions (4.23)–(4.26) in domain (4.22);

(2) We find a $\tilde{T}$-periodic limit function $y^*(\theta, c, \mu)$ of sequence (4.27) starting from $y_0(\theta, c, \mu) = y_0(c) \in \mathcal{B}_{\frac{\tilde{T}}{2} M}$ given by formulae (4.18) and (4.19);

(3) Given the function $y^*(\theta, c, \mu)$, we construct the determining equation

$$\Delta(c, \mu) \equiv \frac{1}{\tilde{T}} \int_0^{\tilde{T}} F\big(\theta, y^*(\theta, c, \mu), \mu\big) \, \mathrm{d}\theta = 0; \tag{4.53}$$

(4) By using certain numerical methods for solving non-linear algebraic or transcendental equations, we find approximately the solution(s) $c = c^*$ of the determining equation (4.53) belonging to the set $D_{\frac{T}{2} M}$ and the value $\mu = \mu^*$ from J;

(5) According to the coordinate transformations (4.4) and (4.13), the function

$$x^*(t) = \Phi\left(\frac{t}{\mu^*}, y^*\left(\frac{t}{\mu^*}, c^*, \mu^* \right) \right) \tag{4.54}$$

gives the T-periodic solution of the autonomous system (4.1) with the period

$$T^* = \mu^* \tilde{T}. \tag{4.55}$$

This solution, by virtue of (4.12), can also be obtained by solving the Cauchy problem with the values of parameters given by (4.53).

The functions

$$x_m(t) = \Phi\left(\frac{t}{\mu^*}, y_m\left(\frac{t}{\mu^*}, c^*, \mu^* \right) \right), \tag{4.56}$$

$$\tilde{x}_m(t) = \Phi\left(\frac{t}{\mu_m}, y_m\left(\frac{t}{\mu_m}, c_m, \mu_m \right) \right) \tag{4.57}$$

are natural to be taken for the mth approximation of the exact T-periodic solution (4.54), where the pair (c_m, μ_m) satisfies the mth approximate determining equation

$$\Delta_m(c,\mu) \equiv \frac{1}{\tilde{T}} \int_0^{\tilde{T}} F\big(\theta, y_m(\theta, c, \mu), \mu\big)\, \mathrm{d}\theta = 0. \tag{4.58}$$

Let us estimate the differences $|x^*(t) - x_m(t)|$ and $|x^*(t) - \tilde{x}_m(t)|$. Assume that, for all $\{\theta_1, \theta_2\} \subset \mathbb{R}$ and $\{y, z\} \subset \mathcal{B}$, function (4.13) satisfies the Lipschitz condition

$$\big|\Phi(\theta_1, y) - \Phi(\theta_2, z)\big| \leqslant |\theta_1 - \theta_2| M_\Phi + K_\Phi |y - z| \tag{4.59}$$

with some non-negative vector $M_\Phi \in \mathbb{R}_+^n$ and matrix $K_\Phi \in \mathrm{GL}_n(\mathbb{R})$. Then, taking into account (4.54), (4.56), and (4.33), we obtain the estimate

$$\begin{aligned} \big|x^*(t) - x_m(t)\big| &= \left|\Phi\left(\frac{t}{\mu^*}, y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right)\right) - \Phi\left(\frac{t}{\mu^*}, y_m\left(\frac{t}{\mu^*}, c^ast, \mu^*\right)\right)\right| \\ &\leqslant K_\Phi \left| y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right) - y_m\left(\frac{t}{\mu^*}, c^*, \mu^*\right)\right| \\ &\leqslant \bar{\alpha}_{1,\tilde{T}}\left(\frac{t}{\mu^*}\right) K_\Phi \left(\frac{3\tilde{T}}{10} K\right)^m \left(I - \frac{3\tilde{T}}{10} K\right)^{-1} M. \end{aligned} \tag{4.60}$$

Furthermore, due to (4.54), (4.57), and (4.59),

$$\begin{aligned} \big|x^*(t) - \widetilde{x}_m(t)\big| &= \left|\Phi\left(\frac{t}{\mu^*}, y^*(\frac{t}{\mu^*}, c^*, \mu^*)\right) - \Phi\left(\frac{t}{\mu_m}, y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right)\right)\right| \\ &\leqslant \left|\frac{1}{\mu^*} - \frac{1}{\mu_m}\right| t M_\Phi + K_\Phi \left| y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right)\right. \\ &\qquad \left. - y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right)\right|. \end{aligned} \tag{4.61}$$

Obviously,

$$\begin{aligned} &\left| y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right) - y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right)\right| \\ &\quad \leqslant \left| y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right) - y_m\left(\frac{t}{\mu^*}, c_m, \mu_m\right)\right| \\ &\qquad + \left| y_m\left(\frac{t}{\mu^*}, c_m, \mu_m\right) - y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right)\right|. \end{aligned} \tag{4.62}$$

The first term in the right-hand side of (4.62) can be estimated by using (4.42):

$$\begin{aligned}&\left|y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right) - y_m\left(\frac{t}{\mu^*}, c_m, \mu_m\right)\right|\\&\quad\leqslant \left[I + \bar{\alpha}_{1,\tilde{T}}(\theta)K\left(I - \frac{3\tilde{T}}{10}K\right)^{-1}\right]\left|y_0(c^*) - y_0(c_m)\right|\\&\qquad + \left[I + \left(I - \frac{3\tilde{T}}{10}K\right)^{-1}\right]\bar{\alpha}_{1,\tilde{T}}(\theta)|\mu^* - \mu_m|\tilde{M}. \qquad (4.63)\end{aligned}$$

Let us put

$$\frac{1}{\mu^*} = \frac{1}{\mu_m} + \frac{1}{\gamma_m}. \qquad (4.64)$$

By virtue of Lemma 3.13, it then follows from (4.27) that

$$\begin{aligned}&\left|y_m\left(\frac{t}{\mu^*}, c_m, \mu_m\right) - y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right)\right|\\&\quad= \Bigg|y_0(c_m) + \int_0^{\frac{t}{\mu^*}}\Bigg[F\big(s, y_{m-1}(s, c_m, \mu_m), \mu_m\big)\\&\qquad - \frac{1}{\tilde{T}}\int_0^{\tilde{T}} F\big(\tau, y_{m-1}(\tau, c_m, \mu_m), \mu_m\big)\,\mathrm{d}\tau\Bigg]\mathrm{d}s\\&\qquad - y_0(c_m) - \int_0^{\frac{t}{\mu_m}}\Bigg[F\big(s, y_{m-1}(s, c_m, \mu_m), \mu_m\big)\\&\qquad - \frac{1}{\tilde{T}}\int_0^{\tilde{T}} F\big(\tau, y_{m-1}(\tau, c_m, \mu_m), \mu_m\big)\,\mathrm{d}\tau\Bigg]\mathrm{d}s\Bigg|\\&\quad= \Bigg|\int_{\frac{t}{\mu_m}}^{\frac{t}{\gamma_m}}\Bigg[F\big(s, y_{m-1}(s, c_m, \mu_m), \mu_m\big)\\&\qquad - \frac{1}{\tilde{T}}\int_0^{\tilde{T}} F\big(\tau, y_{m-1}(\tau, c_m, \mu_m), \mu_m\big)\,\mathrm{d}\tau\Bigg]\mathrm{d}s\Bigg|\\&\quad\leqslant \alpha_{1,\tilde{T}}(t)M, \quad t \in [0, \tilde{T}]. \qquad (4.65)\end{aligned}$$

Combining (4.63) and (4.65), we see that (4.62), (4.61) yield the following estimate:

$$\begin{aligned}\left|x^*(t) - \tilde{x}_m(t)\right| \leqslant{}& \left|\frac{1}{\mu^*} - \frac{1}{\mu_m}\right| t M_\Phi\\&+ K_\Phi\Bigg\{\left[I + \bar{\alpha}_{1,\tilde{T}}\left(\frac{t}{\mu_m}\right)K\left(I - \frac{3\tilde{T}}{10}K\right)^{-1}\right]\\&\times \left|y_0(c^*) - y_0(c_m)\right|\end{aligned}$$

$$+\left[I+\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}\right]\bar{\alpha}_{1,\tilde{T}}\left(\frac{t}{\mu_m}\right)|\mu^*-\mu_m|\tilde{M}\Bigg\}$$
$$+\alpha_{1,\tilde{T}}(t)M, \quad t\in[0,T]. \tag{4.66}$$

REMARK 4.5. By using inequality (4.44) of Theorem 4.4, one can obtain a condition sufficient for the absence of $\tilde{T}$-periodic solutions of system (4.16). Indeed, (4.44) implies

$$\left|\Delta(c,\mu)\right|\geqslant\frac{10\tilde{T}}{27}K\left(\frac{3\tilde{T}}{10}K\right)^{m}\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}M-\left|\Delta_m(c,\mu)\right|.$$

Therefore, the determining equation (4.53) has no solutions (c,μ) in the set $H_f\times J$ whenever

$$\sup_{(c,\mu)\in H_f\times J}\left|\frac{1}{\tilde{T}}\int_0^{\tilde{T}}F\big(\theta,y_m(\theta,c_m,\mu_m),\mu_m\big)\,\mathrm{d}\theta\right|$$
$$>\frac{10\tilde{T}}{27}K\left(\frac{3\tilde{T}}{10}K\right)^{m}\left(I-\frac{3\tilde{T}}{10}K\right)^{-1}M \tag{4.67}$$

for some $m\in\{0,1,2,\ldots\}$. Consequently, it follows from Theorem 4.3 that, under condition (4.67), the $\tilde{T}$-periodic system (4.16) has no $\tilde{T}$-periodic solutions and, hence, the autonomous system (4.1) has no T-periodic solutions.

4.2. *Linear substitution of variables*

It is clear that the simplest case of substitution (4.13) is the linear change of variables

$$x(\theta)=A(\theta)y(\theta)+b(\theta), \quad \theta\in\mathbb{R}, \tag{4.68}$$

where A and b are $\tilde{T}$-periodic matrix and vector-valued functions, respectively. We assume that these functions are continuously differentiable and such that

$$\det A(\theta)\neq 0, \quad \theta\in[0,\tilde{T}]. \tag{4.69}$$

The change of variable (4.68) transforms the autonomous system (4.1) into the non-autonomous system

$$\frac{\mathrm{d}y}{\mathrm{d}\theta}=F(\theta,y,\mu), \tag{4.70}$$

where μ is given by (4.20) and

$$F(\theta,y,\mu):=A(\theta)^{-1}\big[\mu f\big(A(\theta)y+b(\theta)\big)-A'(\theta)y-b'(\theta)\big].$$

The use of the linear substitution (4.68) instead of (4.13) simplifies the transformation of the autonomous system (4.1) to a non-autonomous one and the verification of conditions (4.23)–(4.26). In this case, the initial data (4.11) and (4.19), for which there may exist $\tilde{T}$-periodic solutions of (4.5) and (4.70), are related by the formula

$$x_0(c) = A(0)y_0(c) + b(0), \tag{4.71}$$

whence, in view of (4.69),

$$y_0(c) = A(0)^{-1}\big[x_0(c) - b(0)\big]. \tag{4.72}$$

Therefore, we can start our iteration (4.27) from $y_0(c)$ given by (4.72).

The T-periodic solution of the autonomous system (4.1) is given by the formula

$$x^*(t) = A\left(\frac{t}{\mu^*}\right)y^*\left(\frac{t}{\mu^*}, c^*, \mu^*\right) + b\left(\frac{t}{\mu^*}\right), \tag{4.73}$$

where the pair (c^*, μ^*) is a solution of the determining equation (4.36). Similarly, the approximate solutions (4.56), (4.57) take the form

$$x_m(t) = A\left(\frac{t}{\mu^*}\right)y_m\left(\frac{t}{\mu^*}, c^*, \mu^*\right) + b\left(\frac{t}{\mu^*}\right), \tag{4.74}$$

and

$$\tilde{x}_m(t) = A\left(\frac{t}{\mu_m}\right)y_m\left(\frac{t}{\mu_m}, c_m, \mu_m\right) + b\left(\frac{t}{\mu_m}\right), \tag{4.75}$$

where the pair (c_m, μ_m) is a solution of the approximate determining equation (4.58).

For the linear change of variable (4.68), the vector M_Φ and the matrix K_Φ in the Lipschitz condition (4.59) as well as in the error estimates (4.60), (4.66) are given by the formulae $K_\Phi = \max_{\theta\in[0,\tilde{T}]} |A(\theta)|$,

$$M_\Phi = \max_{(\theta,y)\in[0,\tilde{T}]\times\Omega} \big|A'(\theta)y + f'(\theta)\big|.$$

EXAMPLE 4.6. Let us suppose that the system (4.1) has the form

$$\begin{aligned} x_1'(t) &= f_1\big(x_1(t), x_2(t)\big),\\ x_2'(t) &= f_2\big(x_1(t), x_2(t)\big). \end{aligned} \tag{4.76}$$

Consider (4.76), (4.77) together with the T-periodic boundary conditions

$$x_1(0) = x_1(T), \qquad x_2(0) = x_2(T), \tag{4.77}$$

where $f_1 : \mathbb{R}^n \to \mathbb{R}^p$, $f_2 : \mathbb{R}^n \to \mathbb{R}^{n-p}$, p is even, and T is an positive constant.

Let us use the special case of the linear transformation (4.68) where

$$A(\theta) = \operatorname{diag}\big(\exp(A\theta), I_{n-p}\big), \qquad b(\theta) \equiv 0, \tag{4.78}$$

where A is a real skew-symmetric matrix with purely imaginary simple eigenvalues.

In this case, substitution (4.68) is rewritten as follows:

$$x_1(t) = \exp(A\theta)y_1(\theta), \qquad x_2(\theta) = y_2(\theta), \tag{4.79}$$

and the transformed system (4.16) corresponding to (4.76) has the form

$$\begin{aligned} y_1'(\theta) &= \mu \exp[-\theta A] f_1\big(\exp(\theta A)y_1(\theta), y_2(\theta)\big) - Ay_1(\theta),\\ y_2'(\theta) &= \mu f_2\big(\exp(\theta A)y_1(\theta), y_2(\theta)\big), \end{aligned}$$

where μ is given by (4.20).

EXAMPLE 4.7. Consider the autonomous system of the form

$$\begin{aligned} x_1'(t) &= Ax_1(t) + f_1\big(x_1(t), x_2(t)\big),\\ x_2'(t) &= f_2\big(x_1(t), x_2(t)\big), \end{aligned} \tag{4.80}$$

where $f_1 : \mathbb{R}^n \to \mathbb{R}^p$, $f_2 : \mathbb{R}^n \to \mathbb{R}^{n-p}$, p is even, $T > 0$, and A is a square matrix of dimension p having the same properties as in Example 4.6. Let us assume that the functions f_1 and f_2 are continuous in the domain

$$G = \big\{(x_1, x_2) \mid \|x_1\| \leqslant d, x_2 \in D_2\big\}, \tag{4.81}$$

where $\|x_1\|^2 \equiv \sum_{k=1}^{p} x_{1k}^2$ and D_2 is a closed bounded domain.

Suppose that the functions f_1 and f_2 satisfy the following conditions in domain (4.81): there exist some non-negative constants k_1, m_1, a non-negative vector $M_2 \in \mathbb{R}^{n-p}$, and a non-negative $(n-p) \times n$ matrix K_2 such that

$$\big\|f_1(x)\big\| \leqslant m_1, \qquad \big|f_2(x)\big| \leqslant M_2 \tag{4.82}$$

and

$$\big\|f_1(x_1, x_2) - f_1(z_1, z_2)\big\| \leqslant k_1\|x - z\|, \tag{4.83}$$

$$\big|f_2(x_1, x_2) - f_2(z_1, z_2)\big| \leqslant K_2|x - z| \tag{4.84}$$

for all (x_1, x_2) and (z_1, z_2) from domain (4.81).

The change of variable (4.68) with A given by (4.78) transforms system (4.80) to the form

$$\begin{aligned}\frac{dy_1}{d\theta} &= (\mu - 1)Ay_1 + \mu \exp[-\theta A] f_1\big(\exp(\theta A)y_1, y_2\big)\\ &=: \mu F_1(\theta, y_1, y_2), \\ \frac{dy_2}{d\theta} &= \mu f_2\big(\exp(\theta A)y_1, y_2\big) =: \mu F_2(\theta, y_1, y_2).\end{aligned} \tag{4.85}$$

Since A is skew-symmetric, it follows that the matrices $\exp(\pm\theta A)$ are orthogonal, i.e., $e^{\pm\theta A}(e^{\pm\theta A})^* = I_{p\times p}$ and, furthermore, x_1 and x_2 in (4.79) satisfy the relations

$$\|x_1\| = \|e^{\theta A} y_1\| = \|y_1\|, \tag{4.86}$$

$$\big\|e^{-\theta A} f_1(e^{\theta A} y_1, y_2)\big\| = \big\|f_1(e^{\theta A} y_1, y_2)\big\|. \tag{4.87}$$

It follows from (4.86), (4.87) that the right-hand side of system (4.85) is well defined and continuous in domain (4.81). Moreover, the functions $F_1(\theta, y_1, y_2)$ and $F_2(\theta, y_1, y_2)$ in (4.85) satisfy the inequalities

$$\begin{aligned}&\big|F_1(\theta, y_1, y_2)\big| \leqslant \bar{m}_1 e_p, \qquad \big|F_2(\theta, y_1, y_2)\big| \leqslant M_2, \\ &\big|F_1(\theta, y_1, y_2) - F_1(\theta, z_1, z_2)\big| \leqslant \bar{k}_1 J_{p\times n}|y - z|\end{aligned} \tag{4.88}$$

for all (y_1, y_2) and (z_1, z_2) from domain (4.81), where

$$\begin{aligned}\bar{m}_1 &= m_1 + (1 - \mu^{-1}) \max_{\|y_1\|\leqslant d} \|Ay_1\|, \\ \bar{k}_1 &= k_1 + (1 - \mu^{-1})\|A\|,\end{aligned} \tag{4.89}$$

and m_1 and k_1 are the same as in (4.82), (4.83). Here, e_p and $J_{p\times n}$ are the vector and matrix of dimension $p \times 1$ and $p \times n$, respectively, with all elements equal to 1.

It follows from inequalities (4.88), (4.89) that the functions in the right-hand side of system (4.85) satisfy conditions (4.23) and (4.24) with the vector

$$M = \mu \operatorname{col}(\bar{m}_1 e_p, M_2) \tag{4.90}$$

and matrix

$$K = \mu \begin{pmatrix} \bar{k}_1 J_{p\times n} \\ K_2 \end{pmatrix}, \tag{4.91}$$

where K_2 is the matrix from (4.84).

We thus see that, in some cases (in particular, for system (4.80)) one can verify conditions (4.23), (4.24) in terms of the constants m_1, M_2, k_1, and K_2 involved in conditions (4.82), (4.83), and (4.84) for the original system.

REMARK 4.8. Quite similarly, one can show that, for the autonomous system

$$x'(t) = Ax + f(x)$$

with A having the same properties as in Example 4.7, the linear change of variables

$$x(\theta) = \mathrm{e}^{\theta A} y(\theta) \tag{4.92}$$

brings the $T\mu^{-1}$-periodic problem (4.5), (4.6)

$$\frac{\mathrm{d}x}{\mathrm{d}\theta} = \mu\bigl[Ax + f(x)\bigr], \tag{4.93}$$

$$x(0) = x(\tilde{T}) \tag{4.94}$$

to the non-autonomous $\tilde{T}$-periodic problem (4.94) for the equation

$$\frac{\mathrm{d}y}{\mathrm{d}\theta} = (\mu - 1)Ay + \mu\mathrm{e}^{-\theta A} f(\mathrm{e}^{\theta A} y). \tag{4.95}$$

EXAMPLE 4.9. Let us consider the second-order autonomous differential equation

$$\ddot{x} + \dot{x}^2 + (x - \varepsilon)^2 + x = \varepsilon^2 + \varepsilon, \tag{4.96}$$

where ε is a real parameter, and try do determine the period, T, which a periodic solution of (4.96) may have.

To Eq. (4.96), we associate the first-order system

$$\begin{aligned} \frac{\mathrm{d}x_1}{\mathrm{d}t} &= x_2, \\ \frac{\mathrm{d}x_2}{\mathrm{d}t} &= (2\varepsilon - 1)x_1 - x_1^2 - x_2^2 + \varepsilon \end{aligned} \tag{4.97}$$

and the following T-periodic boundary conditions:

$$x_1(0) = x_1(T), \qquad x_2(0) = x_2(T). \tag{4.98}$$

System (4.97) will be considered for $x_1^2 + x_2^2 \leqslant \varrho^2$, where $\varrho \geqslant 2|\varepsilon|$.

It is clear that (4.97), (4.98) is equivalent to the problem on T-periodic C^2 solutions of (4.96).

Applying the coordinate transformation (4.4) with $\tilde{T} = 2\pi$, we transform (4.97), (4.98) into the system

$$\begin{aligned} \frac{\mathrm{d}x_1}{\mathrm{d}\theta} &= \mu x_2, \\ \frac{\mathrm{d}x_2}{\mathrm{d}\theta} &= \mu\bigl((2\varepsilon - 1)x_1 - x_1^2 - x_2^2 + \varepsilon\bigr) \end{aligned} \tag{4.99}$$

with the 2π-periodic conditions

$$x_1(0)=x_1(2\pi), \qquad x_2(0)=x_2(2\pi). \tag{4.100}$$

In (4.99), according to (4.20), $\mu = T(2\pi)^{-1}$.

Rewriting (4.99), (4.100) as (4.93) by putting

$$A=\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \qquad f(x)=\begin{pmatrix} 0 \\ -x_1^2-x_2^2+2\varepsilon x_1+\varepsilon \end{pmatrix} \tag{4.101}$$

and using transformation (4.92), we arrive at system (4.95) of the form

$$\begin{aligned} \frac{\mathrm{d}y}{\mathrm{d}\theta} &= \mu\Biggl[\left(1-\frac{1}{\mu}\right)\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} y \\ &\quad + \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} f\left(\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} y\right)\Biggr]. \end{aligned} \tag{4.102}$$

Here, we have used the equality

$$\exp(-A\theta)=\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \tag{4.103}$$

easily derived from the series expansion of $\exp(-A\theta)$ in a neighbourhood of 0.

It follows from (4.103) that, in our case, the variable transformation (4.92) is given by the equalities

$$x_1=\cos\theta y_1+\sin\theta y_2, \qquad x_2=-\sin\theta y_1+\cos\theta y_2 \tag{4.104}$$

and, hence, system (4.102) has the form

$$\begin{aligned} \frac{\mathrm{d}y_1}{\mathrm{d}\theta} &= (\mu-1)y_2+\mu\sin\theta\bigl[y_1^2+y_2^2-2\varepsilon(\cos\theta y_1+\sin\theta y_2)-\varepsilon\bigr], \\ \frac{\mathrm{d}y_2}{\mathrm{d}\theta} &= (1-\mu)y_1-\mu\cos\theta\bigl[y_1^2+y_2^2-2\varepsilon(\cos\theta y_1+\sin\theta y_2)-\varepsilon\bigr]. \end{aligned} \tag{4.105}$$

It is obvious from (4.104) that system (4.105) should be considered in the same ϱ-neighbourhood of zero as system (4.97).

We need to verify whether conditions (4.23)–(4.25) hold in our case.

As it has been already pointed out above, the vector M in (4.90) and matrix K in (4.91) are determined directly from the terms in the right-hand side of the original system (4.97), i.e., on base of the properties of function f given by (4.101).

It is easy to see that the function

$$W(x_1,x_2)=-x_1^2-x_2^2+2\varepsilon x_1+\varepsilon$$

takes its maximal value $W_{\max} = -|\varepsilon|(1 + |\varepsilon|)$ when $x_1 = \varepsilon$, $x_2 = 0$, whereas its minimal value $W_{\min} = -[\varrho^2 + 2\varepsilon^2 + (2\varrho + 1)|\varepsilon|]$ is achieved for $x_1 = \varrho \operatorname{sign} \varepsilon$, $x_2 = 0$. Therefore, according to (4.90), we may take the following vector M for system (4.105):

$$M = \mu_2\big[\varrho^2 + 2\varepsilon^2 + (2\varrho + 1)|\varepsilon| + |1 - \mu_2^{-1}|\varrho\big]e_2,$$

where $e_2 = \left[\begin{smallmatrix}1\\1\end{smallmatrix}\right]$.

Furthermore, as can readily be verified, for the number k_1 appearing in (4.83) and (4.89), we may take

$$k_1 = \max_{(x_1,x_2)\in B(0,\varrho)} \sqrt{r\big(\Gamma(x_1, x_2)\big)}, \tag{4.106}$$

where

$$\Gamma(x_1, x_2) = 4\begin{bmatrix} 0 & 0 \\ 0 & (x_1 - \varepsilon)^2 + x_2^2 \end{bmatrix}. \tag{4.107}$$

Indeed, it is easy to see that

$$\Gamma(x) = \frac{\partial f(x)}{\partial x}\left[\frac{\partial f(x)}{\partial x}\right]^*.$$

The maximal eigenvalue of matrix (4.107) is, obviously, given by the formula

$$r\big(\Gamma(x_1, x_2)\big) = 4\big[(x_1 - \varepsilon)^2 + x_2^2\big],$$

whence it follows that, according to (4.106), we may put

$$k_1 = 2\big(\varrho + |\varepsilon|\big).$$

Hence, since $\|\left[\begin{smallmatrix}0 & 1\\-1 & 0\end{smallmatrix}\right]\| = 1$, we see that the constant $\bar{k}_1$ in (4.89) is given by the formula

$$\bar{k}_1 = 2\big(\varrho + |\varepsilon|\big) + \left|1 - \frac{1}{\mu_2}\right|.$$

Therefore, we have the following matrix K in (4.91):

$$K = \mu_2\left[2\big(\varrho + |\varepsilon|\big) + \left|1 - \frac{1}{\mu_2}\right|\right]J_{2\times2},$$

where $J_{2\times2} = \left[\begin{smallmatrix}1 & 1\\1 & 1\end{smallmatrix}\right]$.

Since $r(J_{2\times2}) = 2$, it is not difficult to verify that conditions (4.25) and (4.26) are satisfied in $B(0, \varrho)$ whenever

$$2(\varrho + |\varepsilon|) + \left|1 - \frac{1}{\mu_2}\right| < \frac{5}{6\pi\mu_2} \tag{4.108}$$

and

$$\varrho^2 + 2\varepsilon^2 + (2\varrho + 1)|\varepsilon| + \left|1 - \frac{1}{\mu_2}\right|\varrho < \frac{\varrho}{\pi\mu_2}. \tag{4.109}$$

Inequalities (4.108) and (4.109) hold, for example, when

$$\varepsilon = 0.02, \quad \varrho = 0.06, \quad 0.95 < \mu < 1.05. \tag{4.110}$$

Thus, the techniques described above are applicable to our system (4.97). For system (4.97), Eq. (4.10) with $j = 1$ has the form

$$x_2 = 0$$

and, hence, the one-parametric family of solutions

$$x_1 = c, \qquad x_2 = 0,$$

where $c \in \mathbb{R}$. According to the coordinate transformation (4.92), we have

$$x_1(0) = y_1(0), \qquad x_2(0) = y_2(0).$$

Therefore, we may start the successive approximations (4.27) from the constant function

$$y_0(\theta, c, \mu) = \begin{pmatrix} c \\ 0 \end{pmatrix}.$$

Consider the approximate determining equation (4.58) with $m = 0$ and $\tilde{T} = 2\pi$:

$$\mu \int_0^{2\pi} \sin\theta[c^2 - 2\varepsilon c\cos\theta - \varepsilon]\,\mathrm{d}\theta = 0,$$
$$\int_0^{2\pi} \big[(1-\mu)c - \mu\cos\theta[c^2 - 2\varepsilon c\cos\theta - \varepsilon]\big]\,\mathrm{d}\theta = 0.$$

The first of these two equations is, in fact, an identity for an arbitrary c, whereas the second one means that, for all real c,

$$2\pi(1-\mu)c + 2\varepsilon\mu c\int_0^{2\pi}\cos^2\theta\,\mathrm{d}\theta = 0$$

whence it follows that

$$\mu = \frac{1}{1+\varepsilon},$$

and therefore, in the zero approximation, the period, T, of a solution of Eq. (4.96) is given by the formula

$$T = \frac{2\pi}{1-\varepsilon}.$$

For instance, in the case where ε, ϱ, and μ are given by (4.110), we have $T = 2.04\pi$.

Note that the autonomous equation (4.96) has the periodic solution

$$x(t) = \varepsilon(1+\sin t), \tag{4.111}$$

whose period is equal to 2π. Thus, for ε sufficiently small, even the zero approximation provides a reasonable degree of accuracy for the unknown value of the period.

5. Periodic solutions of differential systems with symmetries

In this section, we study a class of systems of non-linear non-autonomous ordinary differential equations that have "sufficiently many" periodic solutions possessing certain symmetry properties. The symmetry properties considered here (see Definition 5.1) are close to those studied by Hale [28] but, generally speaking, do not coincide with them; see Remark 5.43 in this relation. The theorem obtained in Section 5.7 contains, in particular, Theorem 6 from [70, p. 326] (see also [89]). Similar topics related to symmetries in differential equations were addressed to in the works of Fečkan [18,21–23], Mawhin and Walter [49] Vanderbauwhede [105].

We consider the problem on the T-periodic solutions of the system of n ordinary differential equations

$$x'(t) = f\big(t, x(t)\big), \quad -\infty < t < \infty, \tag{5.1}$$

where $f : \mathbb{R}^{n+1} \to \mathbb{R}^n$ is a certain function periodic in the first variable with the period T.

By a solution of the problem on the T-periodic solutions of system (5.1), we mean a continuously differentiable element of the Banach space C_T^n of continuous vector-functions $(-\infty,\infty) \to \mathbb{R}^n$ periodic with period T. The set of all continuous n-dimensional vector-functions $(-\infty,\infty)$ is denoted by the symbol C^n.

5.1. *Symmetry properties of periodic functions*

We are interested in those properties of the equations of the differential system (5.1) under which the T-periodic solutions of the system are "symmetric" in a certain sense. We restrict ourselves to the consideration of the following symmetry property.

DEFINITION 5.1. (See [63, Definition 3.1].) We say that a function $x \in C_T^n$ *possesses property* (τ, E) (or, alternatively, *is* (τ, E)*-proper*) for certain number τ and non-singular matrix $E \in \mathrm{GL}_n(\mathbb{R})$ if, for all real t, the equality

$$x(t) = Ex(-t-\tau) \tag{5.2}$$

is true.

The set of all functions from C_T^n possessing property (τ, E) will be denoted by $C_T^n(\tau, E)$:

$$C_T^n(\tau, E) := \left\{x \in C_T^n \mid \text{(5.2) holds for all } t \in (-\infty, \infty)\right\}. \tag{5.3}$$

The following lemma is obvious.

LEMMA 5.2. *For arbitrary point* $\tau \in (-\infty, \infty)$ *and non-singular* n*-dimensional matrix* E*, the set* $C_T^n(\tau, E)$ *forms a closed linear subspace in* C_T^n*.*

REMARK 5.3. It is clear from (5.2) that, for $x \in C_T^n(\tau, E)$, the vectors $x(kT)$, where $k = 0, \pm 1, \pm 2, \dots$, are fixed points of the linear operator determined by the matrix E.

The property dealt with in Definition 5.1 above can be regarded as a certain geometrical symmetry of the graph of the function under consideration. In particular, for $E \in \{-\mathbb{1}_n, \mathbb{1}_n\}$, where $\mathbb{1}_n$ stands for the unit matrix of dimension n, Definition 5.1 describes the very natural properties of τ-evenness and τ-oddness understood in the following sense.

DEFINITION 5.4. A function $x \in C_T^n$ will be called τ*-odd* (resp., τ*-even*) if, for an arbitrary t from $(-\infty, \infty)$, equality (5.2) holds with $E = -\mathbb{1}_n$ (resp., with $E = \mathbb{1}_n$).

Clearly, the usual notions of evenness and oddness of a vector-valued function of a scalar variable are obtained immediately from Definition 5.4 when $\tau = 0$.

REMARK 5.5. Properties similar to the τ-evenness and τ-oddness conditions arise in the theory of Fourier series [103]. Similar notions are used, e.g., in [62].

It is easy to construct examples of τ-even and τ-odd functions by using the following

PROPOSITION 5.6. *If a function* $x \in C_T^n$ *is even* (*resp., odd*), *then, for an arbitrary real* τ, *the corresponding function*

$$(-\infty, \infty) \ni t \longmapsto x\left(t + \frac{\tau}{2}\right) \tag{5.4}$$

is τ*-even* (*resp.,* τ*-odd*).

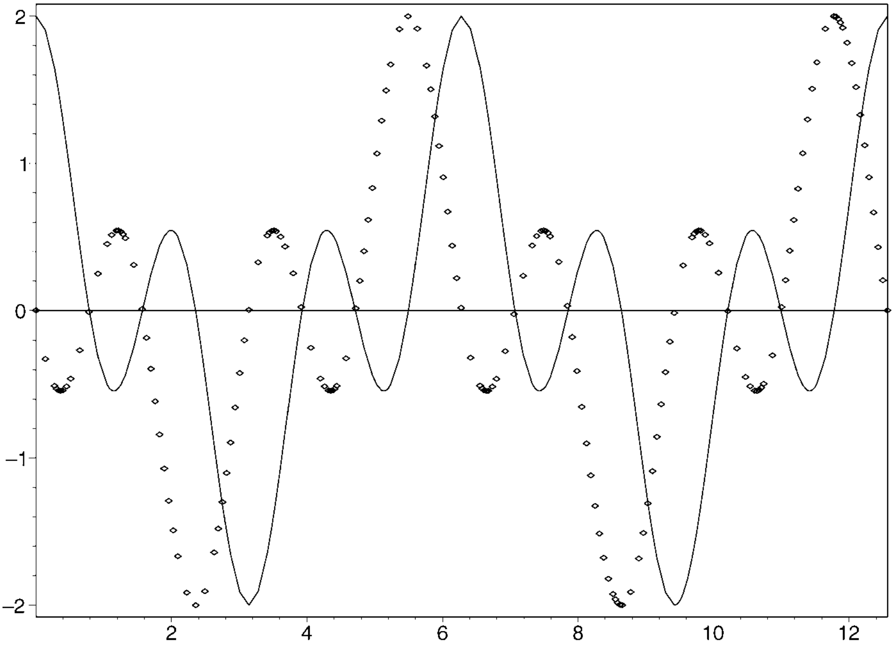

Fig. 1. Functions (5.5) and (5.6).

Proposition 5.6 is easily proved by using Corollary 5.11 of Proposition 5.10 below.

EXAMPLE 5.7. The function

$$u(t) := \cos\left(t + \frac{\pi}{4}\right) - \sin\left(3t + \frac{\pi}{4}\right), \quad t \in (-\infty, \infty), \tag{5.5}$$

is $\frac{\pi}{2}$-even.

Indeed, for the odd function x defined by the formula

$$x(t) := \cos t + \cos 3t, \quad t \in (-\infty, \infty), \tag{5.6}$$

the corresponding function (5.4) is given by equality (5.5). It remains to apply Proposition 5.6 for $T = 2\pi$ and $\tau = \frac{\pi}{2}$.

On Fig. 1, we draw with the “diamond” symbols the graph of the $\frac{\pi}{2}$-even function (5.5) obtained from the even function (5.6) through the shift of the argument by $\frac{\pi}{4}$.

EXAMPLE 5.8. The function

$$u(t) := \sin\left(t + \frac{\pi}{4}\right) - \cos\left(3t + \frac{\pi}{4}\right) - \sin\left(5t + \frac{\pi}{4}\right), \quad t \in (-\infty, \infty), \tag{5.7}$$

is $\frac{\pi}{2}$-odd.

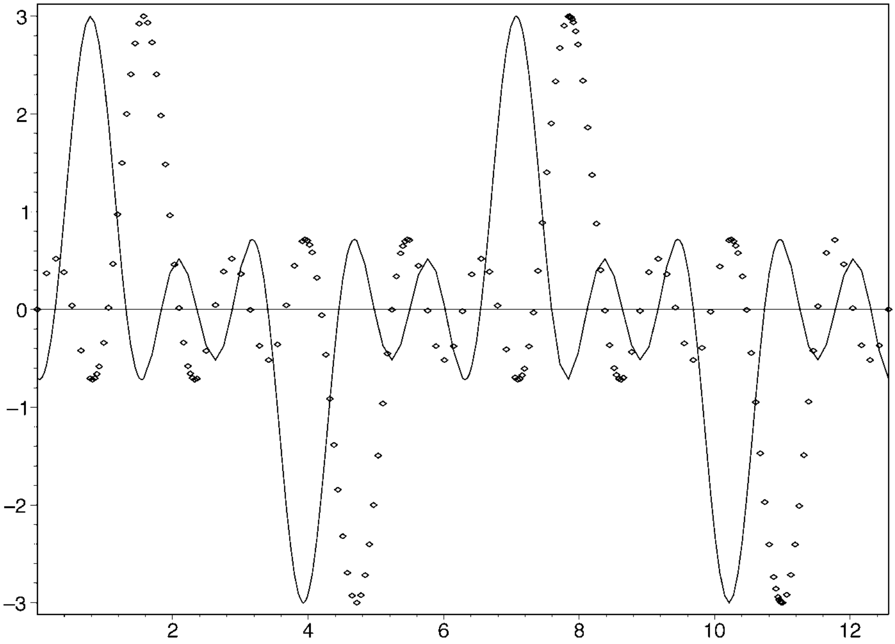

Fig. 2. Functions (5.7) and (5.8).

Indeed, for the even function x given by the formula

$$x(t) := \sin t - \sin 3t + \sin 5t, \quad t \in (-\infty, \infty), \tag{5.8}$$

the corresponding function (5.4) is defined by equality (5.7). Therefore, Proposition 5.6 with $T = 2\pi$ and $\tau = \frac{\pi}{2}$ implies the $\frac{\pi}{2}$-oddness of function (5.7).

On Fig. 2, the “diamond” symbols represent the graph of the $\frac{\pi}{2}$-odd function (5.7) obtained from the even function (5.8) through the shift of the argument by $\frac{\pi}{4}$.

REMARK 5.9. Proposition 5.6 is, in a sense, reversible (see Corollary 5.11 below).

It turns out that the functions with property (τ, E) can be relatively easily constructed from the functions possessing property $(0, E)$, and vice versa. This fact is a consequence of the following

PROPOSITION 5.10. *For arbitrary real σ and τ, the inclusion*

$$S_{-\frac{\tau}{2}} C^n_T(\sigma, E) \subset C^n_T(\sigma + \tau, E), \tag{5.9}$$

holds, where S_h stands for the operator of shift by $h \in [-T, T]$ acting in C^n_T, i.e.,

$$(S_h x)(t) := x(t - h), \quad t \in (-\infty, \infty). \tag{5.10}$$

PROOF. Assume that a certain function x belongs to $C_T^n(\sigma, E)$ and, hence, according to Definition 5.1, satisfies the condition

$$x(t) = Ex(-t-\sigma), \quad t \in (-\infty, \infty). \tag{5.11}$$

Let us set

$$x_\tau := S_{-\frac{\tau}{2}} x. \tag{5.12}$$

By virtue of the definition (5.10) of the operator $S_{-\frac{\tau}{2}}$, the function x_τ thus constructed satisfies the relations

$$\begin{aligned} x_\tau(-t-\sigma-\tau) &= x\left(-t-\sigma-\tau+\frac{\tau}{2}\right) = x\left(-t-\sigma-\frac{\tau}{2}\right) \\ &= x\left(-\left[t+\frac{\tau}{2}\right]-\sigma\right), \end{aligned}$$

whence, by (5.11), we have the relation

$$Ex_\tau(-t-\tau-\sigma) = x\left(t+\frac{\tau}{2}\right), \quad t \in (-\infty, \infty).$$

According to (5.12), the last equality can be rewritten as

$$Ex_\tau(-t-\tau-\sigma) = x_\tau(t), \quad t \in (-\infty, \infty),$$

whence, recalling Definition 5.4, we conclude that x_τ belongs to $C_T^n(\tau+\sigma, E)$. Since x is chosen arbitrarily from $C_T^n(\sigma, E)$, this proves the validity of the required inclusion (5.9). □

COROLLARY 5.11. *If a function* $x \in C_T^n$ *has property* $(0, E)$, *then, for an arbitrary real* τ, *the corresponding function*

$$(-\infty, \infty) \ni t \longmapsto x\left(t+\frac{\tau}{2}\right) \tag{5.13}$$

possesses property (τ, E). *Conversely, if a certain function* $x \in C_T^n$ *has property* (τ, E), *then the corresponding function*

$$(-\infty, \infty) \ni t \longmapsto x\left(t-\frac{\tau}{2}\right)$$

has property $(0, E)$.

PROOF. According to Proposition 5.10, inclusion (5.9) is true, which, for $\sigma = 0$, has the form

$$S_{-\frac{\tau}{2}} C_T^n(0, E) \subset C_T^n(\tau, E).$$

This means that, for an arbitrary function x from $C_T^n(0, E)$, the corresponding function (5.13) has property (τ, E), i.e., the first assertion is true.

On the other hand, for $\sigma = -\tau$, inclusion (5.9) takes the form

$$S_{-\frac{\tau}{2}} C_T^n(-\tau, E) \subset C_T^n(0, E),$$

whence it follows that, for $x \in C_T^n(\tau, E)$, function (5.13) belongs to $C_T^n(0, E)$, Replacing here τ by $-\tau$, we arrive at the second assertion of the corollary. □

The assertions of Corollary 5.11 are illustrated by the diagram

$$\begin{tikzcd} C_T^n(\tau, E) \arrow[r, "S_{\frac{\tau}{2}}"] & C_T^n(0, E) \arrow[r, "S_{-\frac{\tau}{2}}"] & C_T^n(\tau, E). \end{tikzcd}$$

A similar idea can sometimes be applied for the construction of (τ, E)-proper functions from even functions. Namely, the following statement holds.

PROPOSITION 5.12. *If $x \in C_T^n$ is an even function and E is a non-singular matrix of dimension n, then, for an arbitrary n-dimensional square matrix G whose columns belong to the kernel of the matrix $\mathbb{1}_n - E$, the function*

$$(-\infty, \infty) \ni t \longmapsto Gx\left(t + \frac{\tau}{2}\right), \tag{5.14}$$

has property (τ, E).

PROOF. For the function

$$u(t) := Gx\left(t + \frac{\tau}{2}\right)$$

given by formula (5.14), we have

$$Eu(-t - \tau) = EGx\left(-t + \frac{\tau}{2} - \tau\right) = EGx\left(-t - \frac{\tau}{2}\right). \tag{5.15}$$

Since, by assumption, the matrix G is such that

$$EG = G,$$

we see that, for the even functions x, relation (5.15) for an arbitrary $t \in (-\infty, \infty)$ implies the equality

$$Eu(-t - \tau) = u(t),$$

which means that the validity of the assertion required. □

REMARK 5.13. In contrast to Proposition 5.10, the recipe described by Proposition 5.12 is only efficient when $\det(\mathbb{1}_n - E) = 0$ because in the contrary case formula (5.14) defines the function equal identically to zero.

Some further information on the structure of the functions with property (τ, E) is contained in the following

PROPOSITION 5.14. *For an arbitrary function $x \in C_T^n$ having property (τ, E), its value $x(t)$ at every point $t \in (-\infty, \infty)$ belongs to the kernel of the matrix $\mathbb{1}_n - E^2$.*

PROOF. Indeed, let x belong to $C_T^n(\tau, E)$. According to Definition 5.1, this means that, for all real t, equality (5.2) is true, whence

$$x(-t-\tau) = Ex\bigl(-(-t-\tau)-\tau\bigr) = Ex(t), \quad t \in (-\infty, \infty). \tag{5.16}$$

Substituting (5.16) into (5.2), we get the equality

$$x(t) = E^2 x(t), \quad t \in (-\infty, \infty), \tag{5.17}$$

i.e., $x(t) \in \ker(\mathbb{1}_n - E^2)$ for all $t \in (-\infty, \infty)$, as required. □

REMARK 5.15. The peculiar property (5.17) of the functions from $C_T^n(\tau, E)$ that is dealt with in Proposition 5.14, is, obviously, absent when E satisfies the equality

$$E^2 = \mathbb{1}_n. \tag{5.18}$$

Proposition 5.14 yields the following characterisation of the property (τ, E) for the scalar functions.

COROLLARY 5.16. *For an arbitrary point $\tau \in (-\infty, \infty)$, the set $C_T^1(\tau, E)$ consists of the zero function when $E \neq 1$ and coincides with the set of all τ-even functions when $E = 1$.*

PROOF. It follows from Proposition 5.14 that, for an arbitrary (τ, E)-proper scalar function x, identity (5.17) is true. Since, in our case, $E \in (-\infty, \infty)$, it follows that either $E \neq 1$ and x is equal identically to 0, or $E = 1$ and x is τ-even in the sense of Definition 5.4. □

Corollary 5.16 implies that property (τ, E) with E different of $\mathbb{1}_n$ has essentially many-dimensional nature and may be of interest in the cases where $n \geqslant 2$ only.

EXAMPLE 5.17. Assume that τ is a fixed real number and $\theta : (-\infty, \infty) \to (-\infty, \infty)$ is an arbitrary function such that, for a certain $\sigma \in \{-1, 1\}$,

$$\theta(t) = \sigma\theta(-t-\tau), \quad t \in (-\infty, \infty), \tag{5.19}$$

i.e., θ is either τ-even ($\sigma = 1$) or τ-odd ($\sigma = -1$). Let us fix some real α, β, and γ such that $\alpha\beta \neq 0$, and construct the matrix

$$E = \begin{pmatrix} \alpha & \gamma \\ 0 & \beta \end{pmatrix}. \tag{5.20}$$

This matrix is, obviously, non-singular.

The following assertions hold.

(i) For an arbitrary real μ, the function

$$u(t) = \mu\theta(t) \begin{pmatrix} \gamma(\sigma - \alpha)^{-1} \\ 1 \end{pmatrix}, \quad t \in (-\infty, \infty), \tag{5.21}$$

belongs to the class $C_T^2(\tau, E)$ with the matrix E given by

$$E = \begin{pmatrix} \alpha & \gamma \\ 0 & \sigma \end{pmatrix} \tag{5.22}$$

for $\alpha \neq \sigma$.

(ii) For all real λ and μ, the function

$$u(t) = \theta(t) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \quad t \in (-\infty, \infty), \tag{5.23}$$

belongs to the class $C_T^2(\tau, E)$ if the matrix E is given by the formula

$$E = \begin{pmatrix} \sigma & 0 \\ 0 & \sigma \end{pmatrix}.$$

(iii) For arbitrary real λ, the function

$$u(t) = \theta(t) \begin{pmatrix} \lambda \\ 0 \end{pmatrix}, \quad t \in (-\infty, \infty),$$

belongs to the class $C_T^2(\tau, E)$ if matrix (5.20) has the form

$$E = \begin{pmatrix} \sigma & \gamma \\ 0 & \beta \end{pmatrix}$$

with $\beta \neq \sigma$.

It follows immediately from Proposition 5.14 that the functions u of the class $C_T^2(\tau, E)$ take the values in a subspace of a lower dimension. This dimension is either 0 or 1 in our case and, hence, every such function admits representation in form (5.23), where

$\theta:(-\infty,\infty)\to(-\infty,\infty)$ is continuous and T-periodic, and λ and μ are certain constants.

According to Definition 5.1, function (5.23) has property (τ, E) if, and only if, for all $t\in(-\infty,\infty)$,

$$\theta(t)\begin{pmatrix}\lambda\\ \mu\end{pmatrix}=\theta(-t-\tau)\begin{pmatrix}\alpha\lambda+\gamma\mu\\ \beta\mu\end{pmatrix}.$$

Therefore, analysing the system of linear algebraic equations

$$(\sigma-\alpha)\lambda=\gamma\mu,\qquad (\sigma-\beta)\mu=0$$

and taking into account our assumption (5.19) on the function θ, we arrive at the assertions desired.

EXAMPLE 5.18. The function

$$u(t)=\begin{bmatrix}-\cos(t+\frac{\pi}{4})+\sin(3t+\frac{\pi}{4})\\ \frac{1}{3}\cos(t+\frac{\pi}{4})-\frac{1}{3}\sin(3t+\frac{\pi}{4})\end{bmatrix},\quad t\in(-\infty,\infty),\tag{5.24}$$

has property $(\frac{\pi}{2}, E)$ for

$$E=\begin{bmatrix}2&3\\0&1\end{bmatrix}.\tag{5.25}$$

Indeed, it is easy to see that function (5.21) from Example 5.17 has form (5.24) if, for θ, we take the $\frac{\pi}{2}$-even function (5.5) from Example 5.7:

$$\theta(t)=\cos\left(t+\frac{\pi}{4}\right)-\sin\left(3t+\frac{\pi}{4}\right),\quad t\in(-\infty,\infty).\tag{5.26}$$

Matrix (5.25) coincides with (5.22) for $\sigma=1$, $\alpha=2$ and $\gamma=3$.

On Fig. 3, we present the graphs of the first (solid line) and second (“diamonds”) components of function (5.24). By the plus symbol, we draw the graph of the $\frac{\pi}{2}$-even function θ given by formula (5.26).

5.2. *Assumptions*

The implementation of the successive approximation method described below requires some technical assumptions on the function f in the right-hand side of Eq. (5.1). Namely, we assume the following conditions.

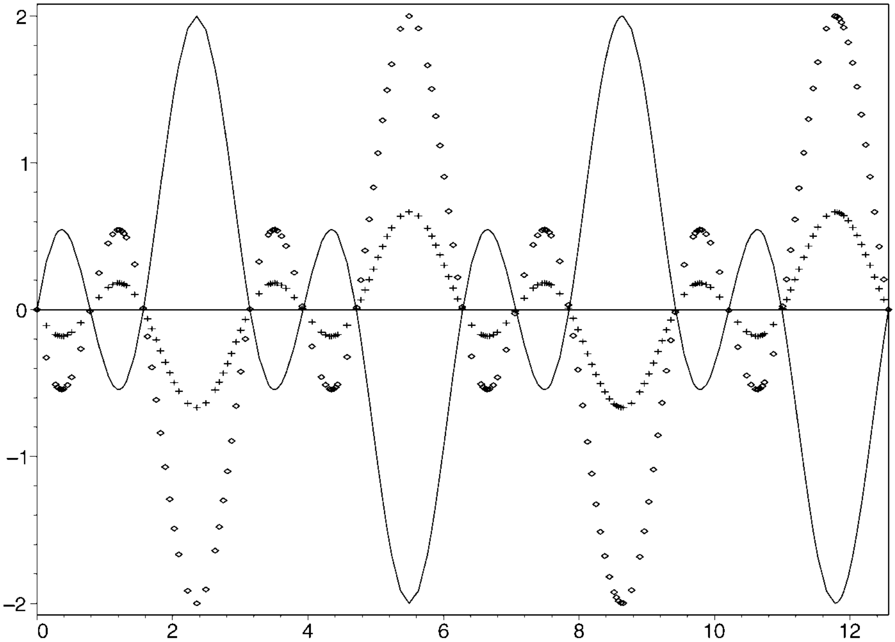

Fig. 3. The components of function (5.24), and function (5.26).

ASSUMPTION 5.19.

(1) The function $f : \mathbb{R}^{n+1} \to \mathbb{R}^n$ is periodic with period T with respect to the first variable and is continuous on the set $\mathbb{R} \times D$, where D is the closure of a bounded domain in $\mathbb{R}^n$.

(2) There exists a matrix-valued function $K : \mathbb{R} \to \mathrm{GL}_n(\mathbb{R})$ with non-negative Riemann integrable elements such that

$$\left| f(t, x_1) - f(t, x_2) \right| \leqslant K(t)|x_1 - x_2| \tag{5.27}$$

for all $t \in (-\infty, \infty)$ and $\{x_1, x_2\} \subset D$.

(3) There exists an non-negative vector $M \in \mathbb{R}^n_+$ such that

$$\frac{1}{2}\left[\max_{(t,x)\in(-\infty,\infty)\times D} f(t,x) - \min_{(t,x)\in(-\infty,\infty)\times D} f(t,x)\right] \leqslant M.$$

(4) The set $D_{\frac{T}{2}M}$ that consists of all the vectors x from $\mathbb{R}^n$ lying in D together with their closed $\frac{T}{2}M$-neighbourhood is non-empty.

REMARK 5.20. Here and below, the inequality sign, the notion of a neighbourhood, and the symbols “max” and “min” are understood componentwise.

5.3. *Auxiliary statements. The operator H_σ*

Given some $\sigma \in (-\infty, \infty)$, for an arbitrary function u from C_T^n, we set

$$(H_\sigma u)(t) = \left(1 + k_\sigma(t) - \frac{t-\sigma}{T}\right) \int_\sigma^{t - Tk_\sigma(t)} u(s)\,\mathrm{d}s \\ + \left(\frac{t-\sigma}{T} - k_\sigma(t)\right) \int_{t - Tk_\sigma(t)}^{T+\sigma} u(s)\,\mathrm{d}s \tag{5.28}$$

at every point $t \in (-\infty, \infty)$. Here, by definition,

$$k_\sigma(t) := \left\lfloor (t-\sigma)T^{-1} \right\rfloor, \tag{5.29}$$

the integer part of the number $(t-\sigma)T^{-1}$.

LEMMA 5.21. *For any $u \in C_T^n$ and $t \in (-\infty, \infty)$, the equality $(H_\sigma u)(t+T) = (H_\sigma u)(t)$ holds.*

This statement is obtained by direct computation. In view of Lemma 5.21, the mapping H_σ given by (5.28) can be regarded as an operator from C_T^n to C_T^n.

Let us set

$$R_{K,T} := r(H_\sigma K), \tag{5.30}$$

where K in the right-hand side of the equality stands for the operator of multiplication by the continuous matrix-valued function $K : (-\infty, \infty) \to \mathrm{GL}_n(\mathbb{R})$ denoted by the same letter,

$$C_T^n \ni u(\cdot) \longmapsto K(\cdot)u(\cdot). \tag{5.31}$$

The symbol $r(A)$, as usual, denotes the spectral radius of a bounded linear operator A. It is clear from Lemma 5.21 that the composition mapping $H_\sigma K$ can be regarded as a linear operator transforming the space C_T^n into itself.

LEMMA 5.22. *For an arbitrary integrable matrix-valued function $K : \mathbb{R} \to \mathrm{GL}_n(\mathbb{R})$, the number $R_{K,T}$ is independent of the value of σ in* (5.30). *Moreover,*

$$R_{K,T} = 1 \Big/ \min\left\{ |\mu| \;\Big|\; \det\left(\frac{T}{\mu}\mathbb{1}_n - \Omega_{\mu K,0}(T) \int_0^T s\,\Omega_{\mu K,0}^{-1}(s)\,\mathrm{d}s \right) = 0 \right\}. \tag{5.32}$$

Here and in the proof below, for $P:[\sigma, T+\sigma]\to \mathrm{GL}_n(\mathbb{R})$, the symbol $\Omega_{P,\sigma}$ stands for the normalised, at the point σ, fundamental matrix of the homogeneous linear differential system

$$x'(t)=\left(1-2\frac{t-\sigma}{T}\right)P(t)x(t),\qquad t\in[\sigma, T+\sigma].$$

PROOF OF LEMMA 5.22. Obviously, it is sufficient to consider the case where not all the elements of the matrix-valued function K are equal identically to zero.

Being compact, the linear integral operator $H_\sigma K : C^n_T \to C^n_T$ has discrete spectrum only. Let, therefore, λ be a non-zero eigenvalue of $H_\sigma K$ and $u \in C^n_T$ be an eigenfunction corresponding to it.

According to (5.29), for $t\in[\sigma, T+\sigma]$, we have $k_\sigma(t)=0$ and, therefore, (5.28) yields

$$\left(1-\frac{t-\sigma}{T}\right)\int_\sigma^t K(s)u(s)\,\mathrm{d}s+\frac{t-\sigma}{T}\int_t^{T+\sigma} K(s)u(s)\,\mathrm{d}s=\lambda u(t). \tag{5.33}$$

If we now set

$$y(t)=\int_\sigma^t K(s)u(s)\,\mathrm{d}s,\qquad t\in[\sigma, T+\sigma], \tag{5.34}$$

then (5.33) implies that, for all t from $[\sigma, T+\sigma]$,

$$\left(1-\frac{t-\sigma}{T}\right)K(t)y(t)+\frac{t-\sigma}{T}K(t)\big[y(T+\sigma)-y(t)\big]=\lambda y'(t). \tag{5.35}$$

Thus, if u is an eigenfunction of the operator $H_\sigma K$ corresponding to the eigenvalue λ, then function (5.34) necessarily satisfies the initial-value problem

$$\begin{aligned}&y'(t)=\frac{1}{\lambda}\left(1-2\frac{t-\sigma}{T}\right)K(t)y(t)+\frac{t-\sigma}{\lambda T}K(t)y(T+\sigma),\\ &\quad t\in[\sigma, T+\sigma],\\ &y(\sigma)=0.\end{aligned} \tag{5.36}$$

The solution of this problem, as can be readily verified, satisfies the functional equation

$$\begin{aligned}&y(t)=\frac{1}{\lambda T}\Omega_{\frac{1}{\lambda}K,\sigma}(t)\int_\sigma^t \Omega^{-1}_{\frac{1}{\lambda}K,\sigma}(s)(s-\sigma)\,\mathrm{d}s\cdot y(T+\sigma),\\ &\quad t\in[\sigma, T+\sigma].\end{aligned} \tag{5.37}$$

Recall that the matrix-valued function $\Omega_{\frac{1}{\lambda}K,\sigma}:[\sigma, T+\sigma]\to \mathrm{GL}_n(\mathbb{R})$ have been defined immediately before the begin of present proof, whereas $\Omega^{-1}_{\frac{1}{\lambda}K,\sigma}$ denotes the matrix inverse for $\Omega_{\frac{1}{\lambda}K,\sigma}$.

Relation (5.37) implies, in particular, that the vector

$$c = y(T+\sigma) \tag{5.38}$$

is a solution of the system of homogeneous linear algebraic equations

$$\left[\lambda \mathbb{1}_n - \frac{1}{T}\Omega_{\frac{1}{\lambda}K,\sigma}(T+\sigma)\int_{\sigma}^{T+\sigma}\Omega^{-1}_{\frac{1}{\lambda}K,\sigma}(s)(s-\sigma)\,\mathrm{d}s\right]c = 0. \tag{5.39}$$

Solution (5.38) of system (5.39) is non-trivial because, in the contrary case, (5.36) and (5.34) imply the triviality of the eigenfunction u of the operator $H_\sigma K$. Thus, for the given λ, the matrix $B_{\frac{1}{\lambda}K,\sigma}$, where

$$B_{P,\sigma} := \lambda \mathbb{1}_n - \frac{1}{T}\Omega_{P,\sigma}(T+\sigma)\int_{\sigma}^{T+\sigma}\Omega^{-1}_{P,\sigma}(s)(s-\sigma)\,\mathrm{d}s, \tag{5.40}$$

is singular. Consequently,

$$R_{K,T} \leqslant \max\left\{|\lambda| \mid \det B_{\frac{1}{\lambda}K,\sigma} = 0\right\}. \tag{5.41}$$

On the other hand, if we assume that

$$\det B_{\frac{1}{\lambda}K,\sigma} = 0 \tag{5.42}$$

for a certain non-zero λ, then there exists a non-trivial solution c of the linear algebraic system (5.39). Then, as can be shown by using (5.42), the unique solution y of the initial-value problem

$$y'(t) = \frac{1}{\lambda}\left(1 - 2\frac{t-\sigma}{T}\right)K(t)y(t) + \frac{t-\sigma}{\lambda T}K(t)c, \quad t \in [\sigma, T+\sigma], \tag{5.43}$$

$$y(\sigma) = 0 \tag{5.44}$$

satisfies Eq. (5.37), whence the validity of equality (5.38) follows. Therefore, the function y is also a solution of problem (5.36).

Let us set

$$u(t) := \frac{1}{\lambda}\left(1 - 2\frac{t-\sigma}{T}\right)y(t) + \frac{t-\sigma}{\lambda T}c, \quad t \in [\sigma, T+\sigma]. \tag{5.45}$$

It is obvious from (5.43) and (5.45) that

$$y'(t) = K(t)u(t), \quad t \in [\sigma, T+\sigma],$$

and, hence, by virtue of (5.44), equality (5.34) is true.

We have thus established the existence of a non-trivial function $u \in C_T^n$ whose corresponding function (5.34) satisfies Eq. (5.35) for all t from $[\sigma, T+\sigma]$. Integrating the expressions on both sides of (5.35) from σ to $t \in [\sigma, T+\sigma]$ and taking (5.44) into account, we obtain that u satisfies relation (5.33), i.e., u is an eigenfunction of the operator $H_\sigma K$ with the eigenvalue λ. Consequently,

$$R_{K,T} \geqslant \max\Big\{|\lambda| \;\Big|\; \det B_{\frac{1}{\lambda}K,\sigma} = 0\Big\}. \tag{5.46}$$

Finally, combining (5.41) and (5.46), we arrive at the equality

$$R_{K,T} = \max\Big\{|\lambda| \;\Big|\; \det B_{\frac{1}{\lambda}K,\sigma} = 0\Big\}. \tag{5.47}$$

Let us now show that the value of $R_{K,T}$ is independent of σ, which fact will justify notation (5.30). Indeed, since, by the well-known property of the fundamental matrix, we have

$$\Omega_{P,\sigma}(t) = \Omega_{P,0}(t)\Omega_{P,\sigma}(0),$$

it follows that

$$\begin{aligned} B_{P,\sigma} &= \lambda\mathbb{1}_n - \frac{1}{T}\Omega_{P,\sigma}(T+\sigma)\int_\sigma^{T+\sigma} \Omega_{P,\sigma}^{-1}(s)(s-\sigma)\,\mathrm{d}s \\ &= \lambda\mathbb{1}_n - \frac{1}{T}\Omega_{P,0}(T+\sigma)\Omega_{P,\sigma}(0)\int_0^T s\Omega_{P,\sigma}^{-1}(0)\Omega_{P,0}^{-1}(s+\sigma)\,\mathrm{d}s \\ &= \lambda\mathbb{1}_n - \frac{1}{T}\Omega_{P,0}(T+\sigma)\int_0^T s\Omega_{P,0}^{-1}(s+\sigma)\,\mathrm{d}s. \end{aligned} \tag{5.48}$$

However,

$$\Omega_0(s+\sigma) = \Omega_0(s)\Omega_0(\sigma),$$

and, therefore, (5.48) yields

$$\begin{aligned} B_{P,\sigma} &= \lambda\mathbb{1}_n - \frac{1}{T}\Omega_{P,0}(T)\Omega_0(\sigma)\int_0^T s\Omega_0^{-1}(\sigma)\Omega_{P,0}^{-1}(s)\,\mathrm{d}s \\ &= \lambda\mathbb{1}_n - \frac{1}{T}\Omega_{P,0}(T)\int_0^T s\Omega_{P,0}^{-1}(s)\,\mathrm{d}s. \end{aligned}$$

The last equality implies, in particular, that the matrix $B_{K\lambda^{-1},\sigma}$, in fact, does not depend on σ. This, by virtue of equality (5.47), means that number (5.30) has the same property.

Finally, setting $\sigma = 0$ in (5.47), we arrive at equality (5.32), which completes the proof of our lemma. □

COROLLARY 5.23. *Let the matrix-valued function* $K:(-\infty,\infty)\to \mathrm{GL}_n(\mathbb{R})$ *have the form*

$$K(t)=\operatorname{diag}\bigl(k_1(t),k_2(t),\dots,k_n(t)\bigr),\quad t\in(-\infty,\infty),$$

where $k_1, k_2, \dots, k_n$ *are certain continuous scalar functions on* $(-\infty,\infty)$. *Then the number* $1/R_{K,T}$ *is equal to the least of the absolute values of the numbers* μ *satisfying the relation*

$$\frac{T}{\mu}=\int_0^T s\exp\biggl[\mu\int_s^T\biggl(1-\frac{2\xi}{T}\biggr)k_\nu(\xi)\,\mathrm{d}\xi\biggr]\,\mathrm{d}s$$

for a certain $\nu\in\{1,2,\dots,n\}$.

PROOF. It remains to notice that, in the case considered, $\Omega_{\mu K,0}(t)$ is a diagonal matrix with the components

$$\exp\biggl[\mu\int_0^t\biggl(1-\frac{2\xi}{T}\biggr)k_\nu(\xi)\,\mathrm{d}\xi\biggr], \tag{5.49}$$

where $\nu\in\{1,2,\dots,n\}$. Applying Lemma 5.22 and substituting functions (5.49) into the expressions for the components of $\Omega_{\mu K,0}(t)$ in (5.32), we obtain the conclusion desired. □

REMARK 5.24. By using the well-known Krein–Rutman theorem on the maximal eigenvalue of a completely continuous positive operator (see Krein and Rutman [38], Theorem 6.2), one can show that, in formula (5.32), one may consider the positive real μ only.

COROLLARY 5.25. *For an arbitrary constant square matrix* K *of dimension* n, *the relation*

$$R_{K,T}\approx\frac{Tr(K)}{3.4161}$$

is true.

The assertion of Corollary 5.25 is known, e.g., from [64].

5.4. *Successive approximations and their convergence*

Having fixed some $\sigma\in(-\infty,\infty)$ and $z\in D_{\frac{T}{2}M}$, we introduce the sequence of functions $\{x_m(\cdot,z)\mid m\geqslant 0\}$ by the recurrence formula

$$x_{m+1}(t,z)=z+\int_\sigma^t f\bigl(s,x_m(s,z)\bigr)\,\mathrm{d}s-\frac{t-\sigma}{T}\int_\sigma^{T+\sigma} f\bigl(s,x_m(s,z)\bigr)\,\mathrm{d}s, \tag{5.50}$$

where $x_0(t,z)=z$ for all $t\in[\sigma,T+\sigma]$. Clearly, all the members of thus defined sequence belong to the space C_T^n.

LEMMA 5.26. *For all $x\in C_T^n$ and $t\in[\sigma,T+\sigma]$, the estimate*

$$\begin{aligned}&\left|\int_\sigma^t\left[x(s)-\frac{1}{T}\int_\sigma^{T+\sigma}x(\xi)\,\mathrm{d}\xi\right]\mathrm{d}s\right|\\&\quad\leqslant\frac{1}{2}\alpha_{1,T}(t-\sigma)\Big(\max_{s\in(-\infty,\infty)}x(s)-\min_{s\in(-\infty,\infty)}x(s)\Big)\end{aligned}\tag{5.51}$$

is true, where $\alpha_{1,T}$ is the function given by formula (3.34).

PROOF. Consider the expression from the left-hand side of the desired inequality (5.51). Taking into account the fact that, for y from C_T^n, the relation

$$\int_\sigma^{T+\sigma}y(s)\,\mathrm{d}s=\int_0^T y(s)\,\mathrm{d}s$$

holds, and carrying out the change of variables $\eta=s-\sigma$ in each of the integrals, we obtain

$$\int_\sigma^t\left[x(s)-\frac{1}{T}\int_0^T x(\xi)\,\mathrm{d}\xi\right]\mathrm{d}s=\int_0^{t-\sigma}\left[x(\xi+\sigma)-\frac{1}{T}\int_0^T x(\eta+\sigma)\,\mathrm{d}\eta\right]\mathrm{d}\xi.$$

In view of Lemma 2.3 from [70], the estimate

$$\left|\int_0^t\left[x(s)-\frac{1}{T}\int_0^T x(\xi)\,\mathrm{d}\xi\right]\mathrm{d}s\right|\leqslant\frac{1}{2}\alpha(t)\Big[\max_{s\in(-\infty,\infty)}x(s)-\min_{s\in(-\infty,\infty)}x(s)\Big]$$

holds for all $x\in C_T^n$ and $t\in(-\infty,\infty)$, where the scalar function α is given by (3.34). This yields that, for $t\in[\sigma,T+\sigma]$,

$$\begin{aligned}&\left|\int_\sigma^t\left[x(s)-\frac{1}{T}\int_0^T x(\sigma)d\xi\right]\mathrm{d}s\right|\\&\quad\leqslant\frac{1}{2}\alpha(t-\sigma)\Big[\max_{\xi\in(-\infty,\infty)}x(\xi+\sigma)-\min_{\xi\in(-\infty,\infty)}x(\xi+\sigma)\Big]\\&\quad=\frac{1}{2}\alpha(t-\sigma)\Big[\max_{\xi\in(-\infty,\infty)}x(\xi)-\min_{\xi\in(-\infty,\infty)}x(\xi)\Big],\end{aligned}$$

which coincides with the required estimate (5.51). The lemma is proved. □

Recall that, throughout all the paper, the inequalities and the symbols max and min are understood in the sense of Remark 5.20.

LEMMA 5.27. *For an arbitrary z from $D_{\frac{T}{2}M}$, the values of all the functions of sequence* (5.50) *belong to D.*

PROOF. The assertion of Lemma 5.27 is established similarly to the argument in Section 2, Chapter 1 of [70]. For this purpose, one should use assumptions 1, 3, and 4. □

Having fixed a certain arbitrary $\sigma \in (-\infty, \infty)$, for all u from C_T^n and $t \in (-\infty, \infty)$, we put

$$(\Lambda_\sigma u)(t) := \int_\sigma^{t - T k_\sigma(t)} u(s)\,\mathrm{d}s - \left(\frac{t-\sigma}{T} + k_\sigma(t)\right) \int_0^T u(s)\,\mathrm{d}s, \tag{5.52}$$

where $k_\sigma : (-\infty, \infty) \to \mathbb{Z}$ is the function defined by formula (5.29). By analogy with Lemma 5.21, it is not difficult to verify that $(\Lambda_\sigma u)(t+T) = (\Lambda_\sigma u)(t)$ for all $u \in C_T^n$ and $t \in (-\infty, \infty)$. Therefore, formula (5.52) defines a (bounded) linear operator $\Lambda_\sigma : C_T^n \to C_T^n$.

LEMMA 5.28. *For arbitrary non-negative u from C_T^n and all $t \in (-\infty, \infty)$, the componentwise inequality*

$$\left|(\Lambda_\sigma u)(t)\right| \leqslant (H_\sigma u)(t) \tag{5.53}$$

is true, where H_σ is the operator in C_T^n defined by formula (5.28).

PROOF. Let u belong to C_T^n, $u \geqslant 0$. Due to the T-periodicity of the functions Λ_σ and H_σ, it suffices to verify the validity of estimate (5.53) for $t \in [\sigma, T+\sigma]$ only.

According to (5.52) and (5.29), for $t \in [\sigma, T+\sigma]$, we have

$$(\Lambda_\sigma u)(t) = \left(1 - \frac{t-\sigma}{T}\right) \int_\sigma^t u(s)\,\mathrm{d}s + \frac{t-\sigma}{T} \int_t^{T+\sigma} u(s)\,\mathrm{d}s,$$

whence

$$\left|(\Lambda_\sigma u)(t)\right| \leqslant \left(1 - \frac{t-\sigma}{T}\right) \int_\sigma^t u(s)\,\mathrm{d}s + \frac{t-\sigma}{T} \int_t^{T+\sigma} u(s)\,\mathrm{d}s.$$

Recalling now the definition (5.28) of the operator H_σ, we arrive at (5.53). □

LEMMA 5.29. *For all $z \in D_{\frac{T}{2}M}$, $t \in (-\infty, \infty)$, and $m = 1, 2, \ldots$, the estimate*

$$\varrho_m(t, z) \leqslant \big(H_\sigma K \varrho_{m-1}(\cdot, z)\big)(t) \tag{5.54}$$

is true, where

$$\varrho_m(t,z) := \left|x_m(t,z) - x_{m-1}(t,z)\right| \tag{5.55}$$

and the functions $x_m(\cdot,z)$ $(m \geqslant 1)$ *are given by the recurrence formula* (5.50).

PROOF. According to Lemma 5.27, for all $z \in D_{\frac{T}{2}M}$, $t \in (-\infty,\infty)$, and $m = 1,2,\ldots,$ we have $x_m(t,z) \in D$. Therefore, in the estimate

$$\begin{aligned}\varrho_{m+1}(t) \leqslant{}& \left(1 - \frac{t-\sigma}{T}\right)\int_\sigma^t \left[f\left(s, x_m(s,z)\right) - f\left(s, x_{m-1}(s,z)\right)\right] \mathrm{d}s \\ &+ \frac{t-\sigma}{T}\int_t^{T+\sigma} \left[f\left(s, x_m(s,z)\right) - f\left(s, x_{m-1}(s,z)\right)\right] \mathrm{d}s, \\ t \in [\sigma, T+\sigma],\end{aligned}$$

which is an easy consequence of Corollary 5.50, we can use inequality (5.27) from assumption 2:

$$\begin{aligned}\varrho_{m+1}(t) \leqslant{}& \left(1 - \frac{t-\sigma}{T}\right)\int_\sigma^t K(s)\left|x_m(s,z) - x_{m-1}(s,z)\right| \mathrm{d}s \\ &+ \frac{t-\sigma}{T}\int_t^{T+\sigma} K(s)\left|x_m(s,z) - x_{m-1}(s,z)\right| \mathrm{d}s, \quad t \in [\sigma, T+\sigma].\end{aligned}$$

Taking notation (5.55) and definition (5.28) of the operator H_σ into account, we arrive immediately at (5.54). Moreover, due to the T-periodicity of the functions considered, relation (5.54) holds for all $t \in (-\infty,\infty)$. The lemma is proved. □

LEMMA 5.30. *Under the assumption that*

$$R_{K,T} < 1, \tag{5.56}$$

for all $z \in D_{\frac{T}{2}M}$, *the sequence* $\{x_m(\cdot,z) \mid m \geqslant 0\}$ *given by formula* (5.50) *converges uniformly to a certain function* $x(\cdot,z) \in C_T^n$. *Furthermore, for all* $[\sigma, T+\sigma]$, *the pointwise and componentwise estimate*

$$\begin{aligned}\left|x_m(\cdot,z) - x(\cdot,z)\right| \leqslant{}& \frac{1}{2}(H_\sigma K)^m (I - H_\sigma K)^{-1} \alpha_{1,T}(\cdot - \sigma) \\ &\times \left[\max_{s\in(-\infty,\infty)} f(s,z) - \min_{s\in(-\infty,\infty)} f(s,z)\right]\end{aligned} \tag{5.57}$$

is true, in which the function $\alpha_{1,T} : \mathbb{R} \to \mathbb{R}$ *is given by formula* (3.34).

For all z indicated, the function $x(\cdot, z)$ is the unique solution of the non-linear integral equation

$$x(t) = z + \int_\sigma^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s - \frac{t-\sigma}{T}\int_0^T f\bigl(s, x(s)\bigr)\,\mathrm{d}s,$$
$$t \in [\sigma, T+\sigma]. \tag{5.58}$$

This solution, moreover, satisfies the differential system (5.1) *if, and only if*

$$\int_0^T f\bigl(s, x(s, z)\bigr)\,\mathrm{d}s = 0. \tag{5.59}$$

The symbol I in inequality (5.57) stands for the identity operator in C_T^n.

PROOF. It is easy to see that the linear continuous operator $H_\sigma K : C_T^n \to C_T^n$ is positive in the sense that the (pointwise and componentwise) inequality $x \geqslant 0$ always yields $H_\sigma K x \geqslant 0$. Then, according to condition (5.56), the inverse operator $(I - H_\sigma K)^{-1}$ exists and, by virtue of the equality

$$(I - H_\sigma K)^{-1} = \sum_{m=0}^{+\infty} (H_\sigma K)^m, \tag{5.60}$$

is positive in the same sense. By virtue of the positivity of the operator $H_\sigma K$, Lemma 5.29 yields the pointwise inequality

$$\varrho_{m+1}(\cdot, z) \leqslant (H_\sigma K)^m \varrho_1(\cdot, z)$$

valid for all $m = 1, 2, 3, \ldots$. Therefore, according to (5.60), we have

$$\begin{aligned}\bigl|x_{m+k}(\cdot, z) - x_m(\cdot, z)\bigr| &\leqslant (H_\sigma K)^m \sum_{\nu=1}^{k} (H_\sigma K)^\nu \varrho_1(\cdot, z)\\ &\leqslant (H_\sigma K)^m \sum_{\nu=1}^{+\infty} (H_\sigma K)^\nu \varrho_1(\cdot, z)\\ &= (H_\sigma K)^m (I - H_\sigma K)^{-1} \varrho_1(\cdot, z).\end{aligned}$$

Thus, the sequence of continuous T-periodic vector-functions on $(-\infty, \infty)$ given by the recurrence formula (5.50) is fundamental in the uniform norm and, hence, is uniformly convergent.

On the other hand, it is clear from (5.55) that, for all (t, z) from $[\sigma, T+\sigma] \times D$,

$$\varrho_1(t,z) \leqslant \frac{1}{2}\alpha_{1,T}(t-\sigma)\Big[\max_{s\in(-\infty,\infty)} f(s,z) - \min_{s\in(-\infty,\infty)} f(s,z)\Big],$$

whence estimate (5.57) immediately follows.

Passing to the limit as $m \to +\infty$ in (5.50), we easily show that the relation

$$\lim_{m\to+\infty} \max_{t\in(-\infty,\infty)} \big|x_m(t,z) - x(t,z)\big| = 0$$

yields (5.58). The continuous differentiability of the function $x(\cdot,z)$ is obvious from the structure of equality (5.58). Differentiating both sides of the relation mentioned, we arrive at the system of non-linear integro-functional equations

$$x'(t,z) = f\big(t, x(t,z)\big) - \frac{1}{T}\int_0^T f\big(s, x(s,z)\big)\,\mathrm{d}s, \quad t \in (-\infty,\infty). \tag{5.61}$$

It is clear from the form of system (5.61) that every solution $x(\cdot,z)$, of system (5.61) satisfying equality (5.59) is also a solution of system (5.1), and *vice versa*. Thus, all the assertions of the lemma are proved. □

REMARK 5.31. It follows from assumption 5.19 that, under the conditions of Lemma 5.30, for all $m \geqslant 1$, the estimate

$$\big|x_m(\cdot,z) - x(\cdot,z)\big| \leqslant \frac{1}{2}(H_\sigma K)^m (I - H_\sigma K)^{-1}\alpha_{1,T}(\cdot-\sigma)M \tag{5.62}$$

holds on $[\sigma, T+\sigma]$. This estimate rougher but simpler than (5.57).

Note that, in the right-hand side of inequalities (5.57) and (5.62), the value of the operator $(H_\sigma K)^m(I - H_\sigma K)^{-1}$ is calculated on the function of the form

$$[\sigma, T+\sigma] \ni t \longmapsto \alpha_{1,T}(t-\sigma)c,$$

where $\alpha_{1,T}$ is the scalar function defined by formula (3.34) and $c \in \mathbb{R}^n$ is a constant vector independent of z.

REMARK 5.32. In the case where

$$K(t) \equiv K, \quad t \in (-\infty,\infty),$$

in assumption 2 from Section 5.2, condition (5.56), according to Corollary 5.25, takes the form

$$r(K) < \frac{3.4161\ldots}{T}, \tag{5.63}$$

where $r(K)$ is the greatest positive eigenvalue of the constant matrix K.

REMARK 5.33. The constant $r = 1/3.41613062\ldots$ has also appeared in [85] in the form $r = \inf_{t\in[0,1]} r(t)$, where $r(t)$, $t \in [0,1]$, is the convergence radius of the Poisson–Abel functional series

$$\sum_{k=0}^{\infty} \alpha_{k,1}(t)\lambda^k, \quad |\lambda| < r, \tag{5.64}$$

and $\alpha_{k,1}$, $k = 1, 2, \ldots$, are the functions given by formulae (3.35) for $T = 1$.

5.5. *Case of "large" Lipschitz constants*

Assuming the global Lipschitz condition 2 ((5.27) in Assumption 5.19), which, in other words, means the fulfilment of inequality (5.27) for arbitrary x and y from $\mathbb{R}^n$, one can drop condition (5.56). For this purpose, one can modify the recurrence formula (5.50) by using certain considerations from the paper of Ronto [61].

Let us consider problem (3.3), (3.4) under the following assumptions.

ASSUMPTION 5.34.

(1) $f : [0,T] \times D \to \mathbb{R}^n$ satisfies the Carathéodory conditions, i.e.,
  (a) The mapping $D \ni x \mapsto f(t,x)$ is continuous for almost every t from $[0,T]$;
  (b) The mapping $[0,T] \ni t \mapsto f(t,x)$ is Lebesgue measurable for all $x \in D$ and, moreover, the function

$$[0,T] \ni t \longmapsto M(t) := \sup_{x\in D} \bigl|f(t,x)\bigr| \tag{5.65}$$

  is Lebesgue integrable.

(2) There exists a matrix-valued function $K : [0,T] \to \mathrm{GL}_n(\mathbb{R})$ with Lebesgue integrable elements such that relation (5.27) holds for a.e. $t \in [0,T]$ and all $\{x_1, x_2\} \subset D$.

Let $\Phi : [0,T] \to \mathrm{GL}_n(\mathbb{R})$ be an arbitrary matrix-valued function with absolutely continuous elements possessing the property

$$\Phi(T) = \Phi(0) + \mathbb{1}_n. \tag{5.66}$$

It is obvious that such functions exist. One can always put, e.g.,

$$\Phi(t) := \operatorname{diag}\left(\frac{t^{\alpha_1} - \tau_1^{\alpha_1}}{T^{\alpha_1}}, \frac{t^{\alpha_2} - \tau_2^{\alpha_2}}{T^{\alpha_2}}, \ldots, \frac{t^{\alpha_n} - \tau_n^{\alpha_n}}{T^{\alpha_n}}\right), \quad t \in [0,T],$$

where $\{\tau_k \mid k = 1, 2, \ldots, n\} \subset \mathbb{R}$ and $\{\alpha_k \mid k = 1, 2, \ldots, n\} \subset (0, +\infty)$.

For any integrable function $x : [0,T] \to \mathbb{R}^n$, we put

$$(W_\Phi x)(t) := \bigl|\mathbb{1}_n - \Phi(t)\bigr| \int_0^t x(s)\,\mathrm{d}s + \bigl|\Phi(t)\bigr| \int_t^T x(s)\,\mathrm{d}s$$

at a.e. $t \in [0, T]$. It is clear that W_Φ can be regarded as a linear mapping from $L_1([0, T], \mathbb{R}^n)$ to $C([0, T], \mathbb{R}^n)$.

Let

$$\beta_\Phi := \max_{t \in [0,T]} (W_\Phi M)(t),$$

where $M : [0, T] \to \mathbb{R}^n$ is the integrable function (5.65) from Assumption 5.34.

ASSUMPTION 5.35. The set D_{β_Φ} is non-empty.

We recall that the set D_{β_Φ} is defined according to formula (1.3) in notation 1, Section 1. Assumption 5.35 means that the set D where f satisfies the Carathéodory and Lipschitz conditions is "large enough."

PROPOSITION 5.36. *Under Assumptions* 5.34 *and* 5.35:

(1) *For any solution x of the periodic problem* (3.3), (3.4), *there exists some $\xi \in \mathbb{R}^n$ such that*

$$x(t) = \xi + \int_0^t f\big(s, x(s)\big)\,\mathrm{d}s - \Phi(t) \int_0^T f\big(s, x(s)\big)\,\mathrm{d}s, \quad t \in [0, T]; \tag{5.67}$$

(2) *For any $\xi \in \mathbb{R}^n$, every solution x of Eq.* (5.67) *satisfies the T-periodic boundary condition* (3.4);

(3) *If $x(\cdot, \xi)$ is a solution of Eq.* (5.67) *and the value of ξ is such that*

$$\int_0^T f\big(s, x(s, \xi)\big)\,\mathrm{d}s = 0, \tag{5.68}$$

then $x(\cdot, \xi)$ also satisfies the differential system (3.3).

For the sake of simplicity, we now assume that

$$\Phi(0) = 0 \tag{5.69}$$

and, therefore, by (5.66), it follows that

$$\Phi(T) = \mathbb{1}_n. \tag{5.70}$$

THEOREM 5.37. (See [61, Theorem 2].) *Under Assumptions* 5.34 *and* 5.35, *there exists an absolutely continuous matrix-valued function $\Phi : [0, T] \to \mathrm{GL}_n(\mathbb{R})$ with properties* (5.69) *and* (5.70) *such that, for any $\xi \in D_{\beta_\Phi}$, Eq.* (5.67) *has a unique absolutely continuous solution $x(\cdot, \xi)$. For all such ξ, the function $x(\cdot, \xi)$ satisfies the relation*

$$\lim_{m \to \infty} \max_{t \in [0,T]} \big| x(t, \xi) - x_m(t, \xi) \big| = 0,$$

where, for any $t \in [0, T]$,

$$x_m(t,\xi) := \xi + \int_0^t f\bigl(s, x_{m-1}(s,\xi)\bigr)\,\mathrm{d}s \\ - \Phi(t)\int_0^T f\bigl(s, x_{m-1}(s,\xi)\bigr)\,\mathrm{d}s, \tag{5.71}$$

and $x_0(\cdot,\xi) \in C([0,T], D)$ *is arbitrary. Furthermore, for all* $m = 1, 2, \ldots$, *the error estimate*

$$|x - x_m| \leqslant \phi_m, \tag{5.72}$$

where

$$\phi_m := (I - W_\Phi K)^{-1}(W_\Phi K)^m |x_1 - x_0|, \tag{5.73}$$

holds coordinatewise and pointwise on $[0, T]$.

In (5.73), the symbol K stands for the operator of multiplication by the matrix-valued function $K : [0,T] \to \mathrm{GL}_n(\mathbb{R})$.

By analogy with formula (3.91), Section 3.2, the properties of sequence (5.71) described in Theorem 5.37 allow us to introduce the functions

$$D_{\beta_\Phi} \ni z \longmapsto \Delta_m(z) := \int_0^T f\bigl(t, x_m(t,z)\bigr)\,\mathrm{d}t \tag{5.74}$$

and consider the equation

$$\Delta_m(\xi) = 0$$

as an approximation of Eq. (5.68).

NOTATION 5.38. Let $G \subset \mathbb{R}^n$, $\Omega \subseteq G$, $\Omega \neq \varnothing$, and $X = (X_k)_{k=1}^n$ and $Y = (Y_k)_{k=1}^n$ be two functions from G to $\mathbb{R}^n$. We write $X \sqsupset_\Omega Y$ if and only if there exists a mapping $k : G \to \{1, 2, \ldots, n\}$ such that $X_{k(\xi)} > Y_{k(\xi)}$ for any $\xi \in \Omega$.

THEOREM 5.39. (See [61, Corollary 3].) *Let* $f : [0,T] \times D \to \mathbb{R}^n$ *satisfy Assumptions* 5.34 *and* 5.35. *Let* $\Phi : [0,T] \to \mathrm{GL}_n(\mathbb{R})$ *be an absolutely continuous matrix-valued function possessing properties* (5.69), (5.70) *and such that*

$$r(W_\Phi K) < 1. \tag{5.75}$$

Assume that the set D_{β_Φ} *contains a certain closed subdomain* Ω *such that, for a certain natural* m, *the relation*

$$|\Delta_m| \sqsupset_{\partial\Omega} \int_0^T K(t)\phi_m(t)\,\mathrm{d}t, \tag{5.76}$$

holds, where $\phi_m : [0, T] \to \mathbb{R}^n$ *is the function given by formula* (5.73). *If moreover,* $\deg(\Delta_m, \Omega, 0) \neq 0$, *then the boundary value problem* (3.3), (3.4) *has a solution* x *with* $x(0) \in \Omega$.

Theorems 5.37 is established with the aid of Theorem 5.39. The proof of Theorem 5.39, in turn, is based upon the following statement [61, Lemma 1].

LEMMA 5.40. *For an arbitrary* $\varepsilon \in (0, \infty)$ *one can specify some* $\delta_\varepsilon \in (0, \infty)$ *such that* $r(W_\Phi K) < \varepsilon$, *provided that* $\max_{k,j=1,2,\dots,n} \int_0^T |\Phi_{kj}(t)|\, \mathrm{d}t < \delta_\varepsilon$.

Here, Φ_{kj}, $k = 1, 2, \dots, n$, stand for the corresponding elements of the matrix $\Phi = (\Phi_{kj})_{k,j=1}^n$. It follows from Lemma 5.40 that an absolutely continuous function $\Phi : [0, T] \to \mathrm{GL}_n(\mathbb{R})$ having properties (5.69), (5.70), and (5.75) exists even in the cases where the integrals $\int_0^T |K_{kj}(t)|\, \mathrm{d}t$, $k, j = 1, 2, \dots, n$, of the elements of the variable matrix $K = (K_{kj})_{k,j=1}^n : [0, T] \to \mathrm{GL}_n(\mathbb{R})$ are arbitrarily large.

Thus, we can always suppose that condition (5.75) of Theorem 5.39 (unlike condition (5.56) of Lemma 5.30) is satisfied.

5.6. *Symmetries* (τ, E) *of solutions of the integral equation* (5.58)

Here, we describe certain conditions under which a certain (generally speaking, infinite) set of solutions of the n-parametric family of Eqs. (5.58) possess property (τ, E). For this purpose, we first state an important property of the linear operator $\Lambda_\sigma : C_T^n \to C_T^n$ given by formula (5.52).

LEMMA 5.41. *For an arbitrary point* $\sigma \in (-\infty, \infty)$ *and an arbitrary non-singular* n-*dimensional matrix* E, *the inclusion*

$$\Lambda_\sigma C_T^n(-2\sigma, -E^{-1}) \subset C_T^n(-2\sigma, E) \tag{5.77}$$

is true.

Inclusion (5.77) of Lemma 5.41 is proved by using [67, Lemma 5]. Recall that the linear set $C_T^n(-2\sigma, E)$ is defined by formula (5.3).

LEMMA 5.42. *Assume that the continuous function* $f : (-\infty, \infty) \times D \to \mathbb{R}^n$, *point* $\tau \in (-\infty, \infty)$, *and the non-singular* n-*dimensional matrix* E *are such that*

$$-f(-t - \tau, z) = Ef(t, Ez) \tag{5.78}$$

for all $z \in \mathbb{R}^n$ *and* $t \in (-\infty, \infty)$. *Then, for an arbitrary* (τ, E)-*proper function* $x \in C_T^n$, *the corresponding function*

$$(-\infty, \infty) \ni t \longmapsto f\big(t, x(t)\big)$$

possesses property $(\tau, -E^{-1})$.

Recall that the symmetry properties (τ, E) and $(\tau, -E^{-1})$ are described by Definition 5.1.

PROOF OF LEMMA 5.42. Let a function $x \in C_T^n$ have property (τ, E). According to Definition 5.1, this means that, for all t from $(-\infty, \infty)$, equality (5.2) is satisfied, whence

$$x(-t-\tau) = E^{-1}x(t), \quad t \in (-\infty, \infty). \tag{5.79}$$

Setting

$$u(t) := f\big(t, x(t)\big), \quad t \in (-\infty, \infty), \tag{5.80}$$

and taking relation (5.79) into account, we get

$$\begin{aligned} -E^{-1}u(-t-\tau) &= -E^{-1}f\big(-t-\tau, x(-t-\tau)\big) \\ &= -E^{-1}f\big(-t-\tau, E^{-1}x(t)\big). \end{aligned} \tag{5.81}$$

Using now condition (5.78) and definition (5.80), from equality (5.81) we find

$$-E^{-1}u(-t-\tau) = u(t), \quad t \in (-\infty, \infty).$$

The last equality means that u has property $(\tau, -E^{-1})$. Since the (τ, E)-proper function u is chosen arbitrarily, we have thus proved our lemma. □

REMARK 5.43. Condition (5.78) resembles condition (6.17) from Hale [28] that, in our notation, has form (5.78) with $\tau = 0$ and the matrix E possessing the properties

$$E^2 = \mathbb{1}_n, \qquad EP_0 = P_0E, \tag{5.82}$$

where P_0 is a certain projection operator defined on the set of continuous T-periodic functions. The former condition is, obviously, more general, because it involves the shift of the argument by an arbitrary τ. Moreover, we do not assume that the matrix E should satisfy (5.82) or any other related conditions used in the work cited.

Lemmata 5.30, 5.41, and 5.42 allow us to obtain the following statement.

THEOREM 5.44. *Assume that, for all real t, the function $f : \mathbb{R}^{n+1} \to \mathbb{R}^n$ satisfies condition* (5.78) *with certain number τ and non-singular n-dimensional matrix E. Let Assump-*

tion 5.19 *be true and, moreover, let inequality* (5.56) *hold. Then, for all* z *from* $D_{\frac{T}{2}M}$ *such that*[2]

$$Ez = z, \tag{5.83}$$

the integro-functional equation

$$\begin{aligned} x(t) = z &+ \int_{-\frac{\tau}{2}}^{t - T\lfloor T^{-1}(t+\frac{\tau}{2})\rfloor} f\big(s, x(s)\big)\,\mathrm{d}s \\ &- \frac{2(t - T\lfloor T^{-1}(t + \frac{\tau}{2})\rfloor) + \tau}{2T} \int_{-\frac{\tau}{2}}^{T-\frac{\tau}{2}} f\big(s, x(s)\big)\,\mathrm{d}s, \\ & t \in (-\infty, \infty), \end{aligned} \tag{5.84}$$

has a unique T*-periodic solution* $x(\cdot, z) : (-\infty, \infty) \to \mathbb{R}^n$*, and this solution possesses property* (τ, E)*.*

Moreover, the fulfilment of equality (5.59) *is necessary and sufficient for the function* $x(\cdot, z)$ *to be a solution of the differential system* (5.1).

Note that the restriction of Eq. (5.84) to the interval $[-\tau/2, T - \tau/2]$ has the form

$$\begin{aligned} x(t) = z &+ \int_{-\frac{\tau}{2}}^{t} f\big(s, x(s)\big)\,\mathrm{d}s \\ &- \frac{2t + \tau}{2T} \int_{-\frac{\tau}{2}}^{T-\frac{\tau}{2}} f\big(s, x(s)\big)\,\mathrm{d}s, \quad t \in \left[-\frac{\tau}{2}, T - \frac{\tau}{2}\right], \end{aligned} \tag{5.85}$$

and that every solution of (5.85) satisfies the condition $x(-\tau/2) = x(T - \tau/2)$.

PROOF. It follows from (5.29) that

$$k_{-\frac{\tau}{2}}(t) = \left\lfloor \frac{1}{T}\left(t + \frac{\tau}{2}\right)\right\rfloor, \quad t \in (-\infty, \infty).$$

Therefore, as can be readily verified, Eq. (5.84) can be rewritten as

$$x = z + \Lambda_{-\frac{\tau}{2}} \mathfrak{f} x,$$

where $\mathfrak{f}$ is the Nemytsky operator generated by the function $f : \mathbb{R}^{n+1} \to \mathbb{R}^n$,

$$u(\cdot) \longmapsto f\big(\cdot, u(\cdot)\big). \tag{5.86}$$

---

[2] A solution of Eq. (5.84) is unique for all $z \in D_{\frac{T}{2}M}$, not only for those satisfying condition (5.83). However, the fulfilment of the property (τ, E) is guaranteed only for those z indicated.

The T-periodicity of the function $f(\cdot, z)$ for z fixed ensures that the operator $\mathfrak{f}$ acts in the space C_T^n. We recall that the operator $\Lambda_{-\frac{\tau}{2}} : C_T^n \to C_T^n$ is defined by formula (5.52) for

$$\sigma = -\frac{\tau}{2}. \tag{5.87}$$

Let us set

$$x_{m+1} = z + \Lambda_{-\frac{\tau}{2}} \mathfrak{f} x_m, \quad m = 0, 1, 2, \ldots, \tag{5.88}$$

where $x_0 \equiv z$. It is obvious from (5.85) that the restriction of (5.88) to $[-\tau/2, T - \tau/2]$ coincides with (5.50) for σ given by (5.87).

Equality (5.83) that, by assumption, is satisfied by z, guarantees that the constant function x_0 belongs to $C_T^n(\tau, E)$ (see Definition 5.1). In view of Lemma 5.42, it follows from (5.78) and (5.87) that the function $\mathfrak{f} x_0$ possesses property $(\tau, -E^{-1})$, i.e., $u \in C_T^n(\tau, -E^{-1})$. By Lemma 5.41, this implies that, together with x_0, the function $\Lambda_{-\frac{\tau}{2}} \mathfrak{f} x_0$, also belongs to $C_T^n(\tau, E)$. Therefore, taking equality (5.88) and Lemma 5.2 into account, we conclude that $x_1 \in C_T^n(\tau, E)$. Arguing similarly, we show that all the members of the sequence of functions (5.88) possess property (τ, E).

Finally, applying Lemma 5.30 with σ given by (5.87) and taking condition (5.56) into account, we conclude that sequence (5.88) converges uniformly to a unique solution of the integro-functional Eq. (5.84). Since, by the consideration above, $x_m \in C_T^n(\tau, E)$ for all $m \geqslant 0$, we see that the corresponding limit function is also an element of the space $C_T^n(\tau, E)$, i.e., has property (τ, E).

It remains to note that the last assertion of Theorem 5.44 is also a consequence of Lemma 5.30. □

5.7. *Periodic solutions with property* (τ, E)

Now we are ready to establish the main theorem of the section. To prove it, besides the results of the preceding subsections, we need the following

LEMMA 5.45. *For an arbitrary function $x \in C_T^n$ having property (τ, G) with certain real τ and non-singular matrix G satisfying the condition*

$$\det(\mathbb{1}_n - G) \neq 0, \tag{5.89}$$

the equality

$$\int_0^T x(s)\,\mathrm{d}s = 0 \tag{5.90}$$

is true.

PROOF. Let us carry out the change of variables $s = -\xi - \tau$ in the integral from the left-hand side of (5.90). Taking into account the T-periodicity of the function $x \in C_T^n(\tau, G)$ and its property (τ, G), we get

$$\begin{aligned} G\int_0^T x(s)\,\mathrm{d}s &= -G\int_{-\tau}^{-T-\tau} x(-\xi-\tau)\,\mathrm{d}\xi \\ &= -G\int_0^{-T} x(-\xi-\tau)\,\mathrm{d}\xi \\ &= G\int_0^{T} x(-\xi-\tau)\,\mathrm{d}\xi \\ &= \int_0^T x(\xi)\,\mathrm{d}\xi, \end{aligned}$$

i.e.,

$$(\mathbb{1}_n - G)\int_0^T x(s)\,\mathrm{d}s = 0. \tag{5.91}$$

In view of (5.89), relation (5.91) yields the required equality (5.90). The lemma is proved. □

The statements obtained above lead us to the following theorem.

THEOREM 5.46. *Let us suppose that Assumption* 5.19[3] *hols for the functions* $f:\mathbb{R}^{n+1}\to\mathbb{R}^n$*, inequality* (5.56) *is true, and, moreover,* f *satisfies condition* (5.78) *with certain real* τ *and non-singular* n*-dimensional matrix* E *such that*

$$\det(\mathbb{1}_n + E) \neq 0. \tag{5.92}$$

Then every solution x *of the system of differential Eqs.* (5.1) *for which the value* $x(-\frac{\tau}{2})$ *belongs to the set* $D_{\frac{\tau}{2}M}$ *and satisfies the equality*

$$x\left(-\frac{\tau}{2}\right) = Ex\left(-\frac{\tau}{2}\right), \tag{5.93}$$

is a T*-periodic solution possessing property* (τ, E).

PROOF. According to Theorem 5.44, under our conditions, the integro-differential equation (5.84) has a unique solution $x(\cdot, z)$ for an arbitrary $z \in \mathbb{R}^n$. For all vectors z satisfying equality (5.83), this solution, moreover, has property (τ, E).

---

[3] Namely, conditions (5.19)–(5.19) from Section 5.2, p. 517.

By Lemma 5.42, condition (5.78) imposed on the function f allows us to claim that the function

$$(-\infty, \infty) \ni t \longmapsto f\bigl(t, x(t, z)\bigr) \tag{5.94}$$

has property $(\tau, -E^{-1})$. Since, obviously,

$$\mathbb{1}_n + E^{-1} = E^{-1}(\mathbb{1}_n + E),$$

this, in view of (5.92), implies that the matrix $G := -E^{-1}$ and function (5.94) belonging to the subspace $C_T^n(\tau, G)$ satisfy the assumptions of Lemma 5.45. The lemma mentioned yields the relation

$$\int_{-\frac{\tau}{2}}^{T-\frac{\tau}{2}} f\bigl(s, x(s, z)\bigr)\, \mathrm{d}s = 0$$

which, by virtue of the T-periodicity of the functions considered, coincides with equality (5.59).

Thus, the solution $x(\cdot, z)$ of Eq. (5.84) for all real t satisfies the relation

$$x(t, z) = z + \int_{-\frac{\tau}{2}}^{t} f\bigl(s, x(s, z)\bigr)\, \mathrm{d}s,$$

whence it follows that this function is a solution of the initial-value problem

$$x'(t) = f\bigl(t, x(t)\bigr), \quad -\infty < t < \infty,$$
$$x\left(-\frac{\tau}{2}\right) = z.$$

On the other hand, we have proved above that $x(\cdot, z)$ lies in $C_T^n(\tau, E)$ and, in particular, is periodic with period T. It remains only to note that all these facts are true for an arbitrary z with property (5.83), which means that every solution of system (5.1) satisfying equality (5.93) belongs to the subspace $C_T^n(\tau, E)$. The theorem is proved. □

A review of the proof of Theorem 5.46 given above allows us to complement it by the following remark.

REMARK 5.47. The derivative of each of the (τ, E)-proper solutions of the differential system (5.1) that are dealt with in Theorem 5.46 has property $(\tau, -E^{-1})$.

In the case where the Lipschitz condition (5.27) for the function f in the right-hand side of system (5.1) is satisfied in the entire space and with a constant matrix, i.e., when (3.5) holds for all $t \in (-\infty, \infty)$ and $\{x_1, x_2\} \subset \mathbb{R}^n$, where $K \in \mathrm{GL}_n(\mathbb{R})$, the conditions of Theorem 5.46 are simplified. Namely, the following statement holds.

COROLLARY 5.48. *Let the continuous function* $f:\mathbb{R}^{n+1}\to\mathbb{R}^n$ *be* T*-periodic in the first variable and satisfy the Lipschitz condition* (3.5) *with a certain* n*-dimensional matrix* K*, whose spectral radius fulfils inequality* (5.63). *Assume also that, for certain real number* τ *and non-singular* n*-dimensional matrix* E *with property* (5.92)*, the function* f *satisfies condition* (5.78).

Then every solution x *of the system of differential Eqs.* (5.1)*, whose value at the point* $-\frac{\tau}{2}$ *satisfies relation* (5.93)*, is a solution periodic with period* T *and possessing property* (τ, E).

A model example of a non-singular matrix E satisfying condition (5.92) of Theorem 5.46 is provided by the unit matrix $E = \mathbb{1}_n$, for which the validity of equality (5.2) means the τ-evenness of the function x. Recall that the notion of a τ-even function is described by Definition 5.4.

COROLLARY 5.49. *If the matrix* K *in the Lipschitz condition* (5.27) *is chosen to be constant, and the continuous function* $f:\mathbb{R}^{n+1}\to\mathbb{R}^n$ *is* T*-periodic with respect to the first variable and satisfies the condition*

$$-f(-t-\tau, z) = f(t, z), \quad -\infty < t < \infty, \tag{5.95}$$

then the fulfilment of inequality (5.63) *guarantees that all the solutions of the differential system* (5.1) *whose values at the point* $-\frac{\tau}{2}$ *lie in the set* $D_{\frac{T}{2}M}$*, are* τ*-even and periodic with period* T.

PROOF. According to Remark 5.32, inequality (5.63) guarantees the fulfilment of condition (5.56). It is also clear that (5.95) is a particular case of (5.78) with $E = \mathbb{1}_n$. Thus, the required assertion is a consequence of Theorem 5.46 for $E = \mathbb{1}_n$. □

The following statement is an immediate consequence of Corollary 5.49.

COROLLARY 5.50. *Let the continuous function* $f:\mathbb{R}^{n+1}\to\mathbb{R}^n$ *be* T*-periodic and odd in the first variable. If, moreover,* f *satisfies the Lipschitz condition* (3.5) *with a matrix* K *whose spectral radius* $r(K)$ *satisfies inequality* (5.63)*, then all the solutions of the differential system* (5.1) *are even and periodic with period* T.

REMARK 5.51. Corollary 5.50 implies, in particular, Theorem 6 from [70, p. 326].

COROLLARY 5.52. *If the function* f *in Eq.* (5.1) *satisfies condition* (5.78) *with a non-singular matrix* E*, then the non-linear differential system* (5.1) *admits the trivial solution.*

PROOF. It is easy to see that, by virtue of (5.78), the function

$$(-\infty, \infty) \ni t \longmapsto f(t, 0)$$

has property $(\tau, -E)$. Proposition 5.14 implies that

$$E^2 f(t,0) = 0, \quad t \in (-\infty, \infty). \tag{5.96}$$

Since E^2 is non-singular, relation (5.96) yields $f(t,0) = 0$ for all $t \in (-\infty, \infty)$. Therefore, system (5.1) admits the trivial solution $x \equiv 0$. □

6. Two-point boundary value problem with non-linear non-separated conditions

In Samoilenko and Ronto [91], Samoilenko and Taĭ [92], the methodology of the successive approximation method is extended in order to make possible studying the non-linear two-point boundary problem of the form

$$y'(t) = f\bigl(t, y(t)\bigr), \quad t \in [0, T], \tag{6.1}$$

$$g\bigl(y(0), y(T)\bigr) = 0, \tag{6.2}$$

for which purpose a general non-linear change of variable was applied to Eq. (6.1). Here, we use a simpler substitution, which, as is shown, essentially facilitates the subsequent application of the successive approximation method. In particular, all the assumptions are formulated in terms of the original problem, and not the transformed one.

6.1. *Reduction to a problem with linear conditions*

Consider the boundary value problem (6.1), (6.2), where the functions $f : [0, T] \times G \to \mathbb{R}^n$ and $g : G \times G \to \mathbb{R}^n$ are continuous, $G \subset \mathbb{R}^n$ being the closure of a bounded domain. Assume that, for $t \in [0, T]$ fixed, f satisfies the Lipschitz condition

$$\bigl|f(t, y_1) - f(t, y_2)\bigr| \leqslant K|y_1 - y_2|, \quad \{y_1, y_2\} \subset G, \tag{6.3}$$

where the square matrix K is supposed to have non-negative components. In (6.3), the absolute value sign and inequality are understood component-wise.

Let us introduce the traditional substitution

$$y(t) = x(t) + w, \tag{6.4}$$

where $w \in \Omega \subset \mathbb{R}^n$ is an unknown parameter. The domain, Ω, of w is chosen so that $D + \Omega \subset G$, whereas the new variable, x, is supposed to have range in D, the closure of a bounded subdomain of G. Substitution (6.4) allows one to rewrite (6.1), (6.2) as

$$x'(t) = f\bigl(t, x(t) + w\bigr), \quad t \in [0, T], \tag{6.5}$$

$$g\bigl(x(0) + w, x(T) + w\bigr) = 0. \tag{6.6}$$

Let us rewrite (6.6) in the form

$$Ax(0) + Bx(T) + g\bigl(x(0) + w, x(T) + w\bigr) = Ax(0) + Bx(T), \tag{6.7}$$

where A and B are some square matrices of dimension n such that $\det B \neq 0$.

The parameter w is natural to be determined from the additional equation

$$Ax(0) + Bx(T) + g\bigl(x(0) + w, x(T) + w\bigr) = 0. \tag{6.8}$$

Due to (6.7), condition (6.8) obviously implies that

$$Ax(0) + Bx(T) = 0. \tag{6.9}$$

Thus, the essentially non-linear problem (6.1), (6.2) is transformed into the equivalent problem (6.5), (6.6), and (6.8).

On the other hand, system (6.5), (6.6), (6.8) can be regarded as a collection of problems (6.9) for the differential system

$$x'(t) = f\bigl(t, x(t) + w\bigr), \tag{6.10}$$

parametrised by the vector parameter w belonging to a certain given set Ω. The essential advantage obtained thereby is that the boundary condition (6.9) is linear. Therefore, problems of the family (6.10), (6.9) can be studied by using the successive approximation method developed in [90,91].

Assume that

$$D_\beta := \bigl\{x \in \mathbb{R}^n \mid B\bigl(x, \beta(x)\bigr) \subset D\bigr\} \neq \varnothing, \tag{6.11}$$

where

$$\beta(x) := \frac{T}{4}\delta_G(f) + \bigl|(B^{-1}A + \mathbb{1}_n)x\bigr|. \tag{6.12}$$

Here, by definition,

$$\delta_G(f) := \max_{(t,y)\in[0,T]\times G} f(t, y) - \min_{(t,y)\in[0,T]\times G} f(t, y). \tag{6.13}$$

Moreover, we suppose that

$$r(K) < \frac{10}{3T}. \tag{6.14}$$

Introduce the sequence of functions

$$\begin{aligned} x_{m+1}(t, w, z) := z &+ \int_0^t f\bigl(s, x_m(s, w, z) + w\bigr)\,\mathrm{d}s \\ &- \frac{t}{T}\int_0^T f\bigl(s, x_m(s, w, z) + w\bigr)\,\mathrm{d}s - \frac{t}{T}(B^{-1}A + \mathbb{1}_n)z, \end{aligned} \tag{6.15}$$

where $m = 0, 1, \ldots$ and $x_0(t, w, z) \equiv z$. It is easily seen that all the members of sequence (6.15) satisfy condition (6.9) for every $z \in D_\beta$ and $w \in \Omega$. Furthermore, $x_m(0, w, z) = z$ for all $m \in \mathbb{N}$.

By virtue of (6.9), a solution x of (6.10), (6.9) satisfies the condition

$$x(T) = -B^{-1}Ax(0)$$

and, therefore, Eq. (6.8) can be rewritten as

$$g\bigl(x(0) + w, -B^{-1}Ax(0) + w\bigr) = 0. \tag{6.16}$$

Summarising the above-said, we conclude that problem (6.10), (6.9), (6.8) is equivalent to system (6.10), (6.9), (6.16). We suggest to solve it sequentially: first solve (6.10), (6.9), and then try to determine whether (6.16) can be fulfilled.

THEOREM 6.1. *Assume conditions* (6.3), (6.11), *and* (6.14). *Then*:

(1) *Sequence* (6.15) *has a limit* $x^*(\cdot, w, z)$ *uniform in* $(t, w, z) \in [0, T] \times D \times D_\beta$;

(2) *The limit function* $x^*(\cdot, w, z)$ *is a solution of problem* (6.9) *for the "perturbed" differential system*

$$x'(t) = f\bigl(t, x(t) + w\bigr) + \Delta(w, z), \quad t \in [0, T],$$

where, by definition,

$$\Delta(w, z) := -\frac{1}{T}(B^{-1}A + \mathbb{1}_n) - \frac{1}{T}\int_0^T f\bigl(s, x^*(s, w, z)\bigr)\, \mathrm{d}s.$$

Furthermore, $x^*(0, w, z) = z$.

(3) *The error estimate*

$$\bigl|x^*(t, w, z) - x_m(t, w, z)\bigr| \leqslant \frac{20}{9}t\left(1 - \frac{t}{T}\right)Q^{m-1}(\mathbb{1}_n - Q)^{-1}\left[\frac{1}{2}\delta_G(f) + K\bigl|(B^{-1}A + \mathbb{1}_n)z\bigr|\right] \tag{6.17}$$

holds, where $Q := \frac{3T}{10}K$ *and* $\delta_G(f)$ *is as in* (6.13).

PROOF. It is carried out similarly to that of Theorem 1 from [68] and Theorem 2.1 from [91, p. 32]. □

The following statement shows the relation of the function $x^*(\cdot, w, z)$ to problem (6.10), (6.9).

THEOREM 6.2. *Under assumptions* (6.3), (6.11), *and* (6.14), *the function* $x^*(\cdot, w, z^*)$ *is a solution of the boundary value problem* (6.10), (6.9) *if, and only if* $z = z^*$ *satisfies the "determining equation,"*

$$\bigl(B^{-1}A + \mathbb{1}_n\bigr)z + \int_0^T f\bigl(s, x^*(s, w, z)\bigr)\,\mathrm{d}s = 0,$$

where w *is considered as a parameter.*

PROOF. Analogous to that of Theorem 2.4 from the book of Samoilenko and Ronto [91, p. 36]. ☐

THEOREM 6.3. *Assume conditions* (6.3), (6.11), *and* (6.14). *Then, for the function* $x^*(\cdot, w, z^*)$ *to be a solution of the boundary value problem* (6.1), (6.2), *it is sufficient that the parameters* $z = z^*$, $w = w^*$ *satisfy the system of determining equations*

$$(B^{-1}A + \mathbb{1}_n)z + \int_0^T f\bigl(s, x^*(s, w, z)\bigr)\,\mathrm{d}s = 0, \tag{6.18}$$

$$g(z + w, -B^{-1}Az + w) = 0. \tag{6.19}$$

In this case,

$$y^*(t) = x^*\bigl(t, w^*, z^*\bigr) + w^* \tag{6.20}$$

is a solution of the boundary value problem (6.1), (6.2).

PROOF. It is obvious from the form of substitution (6.4) that Eqs. (6.18) and (6.19) hold whenever the transformed boundary value problem (6.10), (6.9), (6.16) coincides with (6.1), (6.2). ☐

REMARK 6.4. In [92,91], a change of variable more general than (6.4) was used,

$$y(t) = x(t) + h(t, w). \tag{6.21}$$

However, when $\partial h(t, w)/\partial t \not\equiv 0$, substitution (6.21) leads one to a more complicated transformed boundary value problem, as well as more complicated recursion sequence and determining equations. Furthermore, the basic assumptions should then be made on the *transformed* differential equation.

REMARK 6.5. Considering (6.20), on can treat the function

$$y_m(t) = x_m(t, w_m, z_m) + w_m \tag{6.22}$$

as the mth approximation to the exact solution, $y^*(\cdot, w^*, z^*)$, of the boundary value problem (6.1), (6.2). In (6.22), w_m and z_m are solutions of the "approximate determining equations,"

$$(B^{-1}A + \mathbb{1}_n)z + \int_0^T f\bigl(s, x_m(s, w, z)\bigr)\,\mathrm{d}s = 0, \tag{6.23}$$

$$g(z + w, -B^{-1}Az + w) = 0, \tag{6.24}$$

and $x_m(\cdot, z, w)$ is given by (6.15). We do not consider the strict substantiation, referring the reader to [91] where similar techniques are described.

REMARK 6.6. It follows from the consideration in Section 7.2 that the convergence of the recursion sequence (6.15) can be proved under the condition $r(K) < 3.4161\ldots \cdot T^{-1}$, which is weaker than (6.14). However, estimate (6.17) does not hold in this case.

REMARK 6.7. By using an idea from [61], one can obtain similar statements based on replacing (6.15) by the sequence

$$\begin{aligned} x_{m+1}(t, w, z) := z - (A + B)z + \int_0^t f\bigl(s, x_m(s, w, z) + w\bigr)\,\mathrm{d}s \\ - \Phi(t)\int_0^T f\bigl(s, x_m(s, w, z) + w\bigr)\,\mathrm{d}s, \end{aligned}$$

where Φ is an arbitrary continuous matrix-valued function such that

$$A\Phi(0) + B\Phi(T) = \mathbb{1}_n.$$

In this case, the restrictive conditions of type (6.14) can be avoided. However, an analogue of condition (6.11) is more difficult to verify unless f in Eq. (6.1) is globally Lipschitzian.

EXAMPLE 6.8. Consider the differential equation

$$y''(t) + \frac{t}{16}y(t) + \frac{t}{4}\bigl(y'(t)\bigr)^2 = \frac{t^2}{128}, \quad t \in [0, 1], \tag{6.25}$$

under the non-linear boundary conditions

$$\begin{aligned} &y'(1)y'(0) + \frac{1}{4}y(0) = 0, \\ &y(1)y'(0) - \frac{1}{2}y'(1) = -\frac{7}{128}. \end{aligned} \tag{6.26}$$

We reduce Eq. (6.25) to the first order system

$$\begin{aligned} y_1'(t) &= y_2(t), \\ y_2'(t) &= \frac{t^2}{128} - \frac{t}{16} y_1(t) - \frac{t}{4} y_2^2(t); \end{aligned} \tag{6.27}$$

conditions (6.26) then rewrite as

$$\begin{aligned} y_2(1) y_2(0) + \frac{1}{4} y_1(0) &= 0, \\ y_1(1) y_2(0) - \frac{1}{2} y_2(1) &= -\frac{7}{128}. \end{aligned}$$

Put $A = B = I_2$ and $T = 1$. It is not difficult to verify that the assumptions of the theorems above hold in the domain $G := \{(y_1, y_2) \mid |y_1| \leqslant 1, |y_2| \leqslant \frac{1}{2}\}$.

Namely, relation (6.11) holds whenever β from (6.12) satisfies the component-wise inequality

$$\beta(x_1, x_2) \leqslant \begin{pmatrix} \frac{1}{4} \\ \frac{17}{256} \end{pmatrix} + 2 \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

The vector function in the right-hand side of (6.27) satisfies (6.3) in G with $K = \left(\begin{smallmatrix} 0 & 1 \\ \frac{1}{16} & \frac{1}{4} \end{smallmatrix}\right)$. Since $r(K) = (1 + \sqrt{2})/4$, it is obvious that (6.14) holds.

Substitution (6.4) in (6.27) leads us to the system

$$\begin{aligned} x_1'(t) &= x_2(t) + w_2, \\ x_2'(t) &= \frac{t^2}{128} - \frac{t}{16}\big[x_1(t) + w_1\big] - \frac{t}{4}\big[x_2(t) + w_2\big]^2. \end{aligned}$$

In this case, the determining equation (6.24) has the form

$$\begin{aligned} w_2^2 - z_2^2 + \frac{1}{4}(z_1 + w_1) &= 0, \\ (w_1 - z_1)(w_2 + z_2) - \frac{1}{2}(w_2 - z_2) &= -\frac{7}{128}. \end{aligned} \tag{6.28}$$

Let us find the first approximation, $x_1 = \left(\begin{smallmatrix} x_{1,1} \\ x_{1,2} \end{smallmatrix}\right)$, in the sense of Remark 6.5. According to (6.15), we have

$$\begin{aligned} x_{1,1}(t, w_1, w_2, z_1, z_2) &= z_1 - 2t z_1, \\ x_{1,2}(t, w_1, w_2, z_1, z_2) &= z_2 + \frac{t^3}{384} - \frac{t^2}{32}(z_1 + w_1) - \frac{t^2}{8}(z_1 + w_2)^2 - \frac{t}{384} \\ &\quad + \frac{t}{32}(z_1 + w_1) + \frac{t}{8}(z_2 + w_2)^2 - 2t z_2. \end{aligned}$$

The first approximate determining equation (6.23) (i.e., that corresponding to $m = 1$), is equivalent to $\Delta_1(w, z) = 0$, where the function $\Delta_1 = \binom{\Delta_{1,1}}{\Delta_{1,2}}$ is given by the formula

$$\Delta_{1,1}(w_1, w_2, z_1, z_2) = \frac{385}{192} z_1 - \frac{1}{1536} + \frac{1}{192} w_1 + \frac{1}{48} (z_2 + w_2)^2 + w_2 \tag{6.29}$$

and

$$\begin{aligned}
\Delta_{1,2}(w_1, w_2, z_1, z_2) = {} & -\frac{1}{15360} z_1 z_2 w_2 + \frac{36863}{14155776} + \frac{107531}{10321920} z_1 \\
& + \frac{46079}{23040} z_2 - \frac{322549}{10321920} w_1 + \frac{1}{5760} w_2 \\
& - \frac{1}{15360} w_1 z_2 w_2 - \frac{1}{15360} {z_2}^4 - \frac{1}{15360} {w_2}^4 \\
& - \frac{107509}{2580480} {z_2}^2 + \frac{107531}{1290240} z_2 w_2 - \frac{322549}{2580480} {w_2}^2 \\
& - \frac{1}{245760} {z_1}^2 - \frac{1}{122880} z_1 w_1 - \frac{1}{30720} z_1 {z_2}^2 \\
& - \frac{1}{30720} z_1 {w_2}^2 - \frac{1}{245760} {w_1}^2 - \frac{1}{30720} w_1 {z_2}^2 \\
& - \frac{1}{30720} w_1 {w_2}^2 - \frac{1}{3840} {z_2}^3 w_2 - \frac{1}{2560} {z_2}^2 {w_2}^2 \\
& - \frac{1}{3840} z_2 {w_2}^3 + \frac{1}{3840} z_2 z_1 + \frac{1}{3840} z_2 w_1 \\
& - \frac{1}{320} {z_2}^2 w_2 - \frac{3}{320} z_2 {w_2}^2 - \frac{1}{768} w_2 z_1 \\
& - \frac{1}{768} w_2 w_1 + \frac{1}{960} {z_2}^3 - \frac{1}{192} {w_2}^3 .
\end{aligned} \tag{6.30}$$

Solving system (6.28) together with the approximate determining equations

$$\Delta_{1,1}(w_1, w_2, z_1, z_2) = 0, \qquad \Delta_{1,2}(w_1, w_2, z_1, z_2) = 0,$$

where $\Delta_{1,1}$ and $\Delta_{1,2}$ are given by (6.29) and (6.30), we obtain the following values for $z_1 = \binom{z_{1,1}}{z_{1,2}}$ and $w_1 = \binom{w_{1,1}}{w_{1,2}}$:

$$z_{1,1} \approx -0.06206890391, \qquad z_{1,2} \approx -0.00001967788609,$$
$$w_{1,1} \approx -0.0002202244703, \qquad w_{1,2} \approx 0.1247889518.$$

With these values of parameters, the first approximation, x_1, has the form

$$x_{1,1}(t) \approx -0.06228912838 + 0.1241378078t,$$

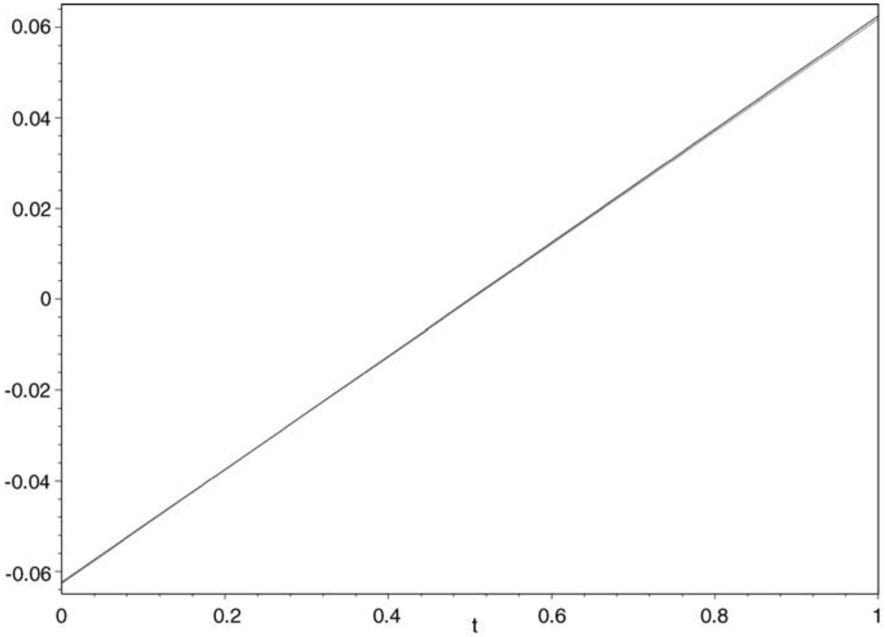

Fig. 4. The exact solution and the first approximation (Example 6.8, problem (6.25), (6.26)). The curves graphically almost coincide with one another.

$$
\begin{aligned}
x_{1,2}(t) \approx{}& -0.196778861 \times 10^{-4} + \frac{1}{384}t^3 + 0.613798 \times 10^{-6}t^2 \\
&- 0.2565424693 \times 10^{-2}t.
\end{aligned}
$$

Consequently, according to substitution (6.4), the solution, y, of problem (6.25), (6.26), up to the first approximation $y_1(t) = x_1(t) + w_1$, has the form

$$
\begin{aligned}
y_{1,1}(t) &\approx -0.06250935285 + 0.1241378078t, \\
y_{1,2}(t) &\approx 0.1247692739 + \frac{1}{384}t^3 + 0.613798 \times 10^{-6}t^2 \\
&\quad - 0.2565424693 \times 10^{-2}t.
\end{aligned}
$$

Note that the function $y^*(t) = \frac{t}{8} - \frac{1}{16}$ is an exact solution of problem (6.25), (6.26). As is seen from Figs. 4 and 5, the graphs of the exact solution and the first approximation almost coincide, whereas the deviation of their derivatives does not exceed 0.001. Thus, even the first iteration of the method gives a satisfactory approximation for the solution of the problem considered.

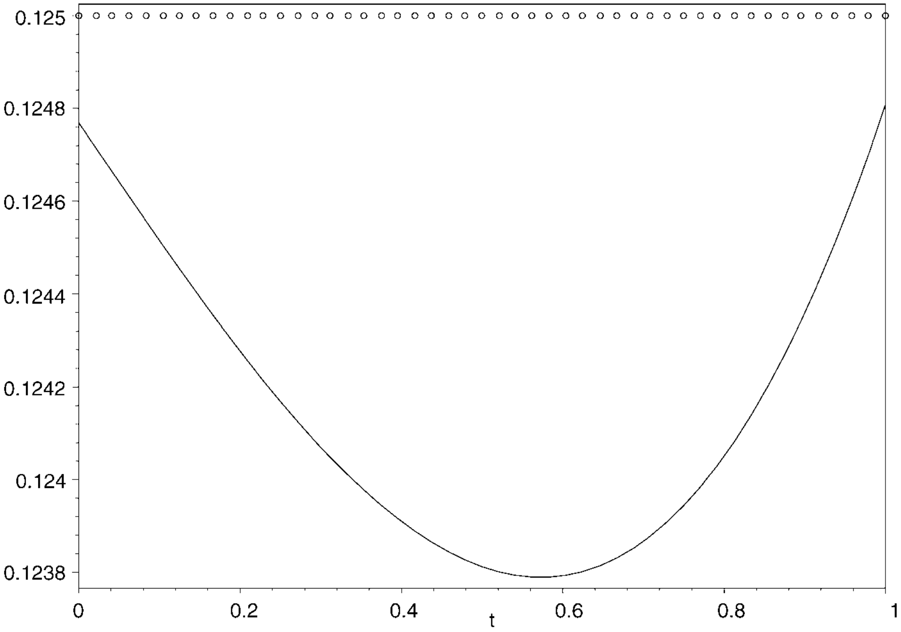

Fig. 5. The derivatives of the exact solution and the first approximation (Example 6.8, problem (6.25), (6.26)).

6.2. *A separated non-linear boundary condition*

It turns out that, in the case of separated, in a sense, boundary conditions, the successive approximation method can be applied without any change of variable.

Consider the two-point boundary value problem

$$x'(t) = f\big(t, x(t)\big), \quad t \in [0, T], \tag{6.31}$$

$$x(T) = a\big(x(0)\big), \tag{6.32}$$

where $a : D \to \mathbb{R}^n$ is continuous and f satisfies conditions (6.3) and (6.14) in the closure, D, of a bounded domain from $\mathbb{R}^n$.

Put $\gamma(x) := \frac{T}{4}\delta_D(f) + |a(x) - x|$, $x \in D$, and assume that

$$D_\gamma \neq \varnothing, \tag{6.33}$$

where the set D_γ is defined similarly to (6.11), whereas the number $\delta_D(f)$ is given by (6.13). Introduce the sequence of functions

$$\begin{aligned} x_{m+1}(t, z) := {} & z + \int_0^t f\big(s, x_m(s, z)\big)\,\mathrm{d}s \\ & - \frac{t}{T}\int_0^T f\big(s, x_m(s, z)\big)\,\mathrm{d}s + \frac{t}{T}\big[a(z) - z\big], \end{aligned} \tag{6.34}$$

where $m = 0, 1, \dots$ and $x_0(t, z) \equiv z \in D_\gamma$. Obviously, all the members of sequence (6.34) satisfy condition (6.32) for every $z \in D_\gamma$.

THEOREM 6.9. *Assume conditions* (6.3), (6.14), *and* (6.33). *Then*:

(1) *Sequence* (6.34) *converges uniformly in* $[0, T] \times D_\gamma$,

$$\lim_{n\to+\infty} \sup_{(t,z)\in[0,T]\times D_\gamma} \left\| x_n(t, z) - x^*(t, z)\right\| = 0.$$

1. *The function* $x^*(\cdot, z)$ *is a solution of problem* (6.32) *for the "perturbed" system*

$$x'(t) = f\big(t, x(t)\big) + \Delta(z), \quad t \in [0, T],$$

where

$$\Delta(z) := \frac{1}{T}\left(a(z) - z - \int_0^T f\big(s, x^*(s, z)\big)\, \mathrm{d}s\right).$$

Moreover, $x^*(\cdot, z)$ *satisfies* $x^*(0, z) = x_m(0, z) = z$ $(\forall m \in \mathbb{N})$.

(3) *The error estimate*

$$\begin{aligned} \left|x^*(t, w, z) - x_m(t, w, z)\right| \leqslant \frac{20}{9} t\left(1 - \frac{t}{T}\right) Q^{m-1}(\mathbb{1}_n - Q)^{-1} \\ \times \left[\frac{1}{2}\delta_D(f) + K\left|a(z) - z\right|\right] \end{aligned} \tag{6.35}$$

holds, where $Q := \frac{3T}{10}K$ *and* $\delta_D(f)$ *is defined by* (6.13).

PROOF. Analogous to that of Theorem 2.1 from [91, p. 32]. □

THEOREM 6.10. *Under conditions of Theorem* 6.9, *the limit function of sequence* (6.34) *is a solution of problem* (6.31), (6.32) *if, and only if the parameter* $z = z^*$ (*which stands for the initial value of the solution at* $t = 0$) *satisfies the determining equation*

$$a(z) - z = \int_0^T f\big(s, x^*(s, z)\big)\, \mathrm{d}s.$$

PROOF. Similar to that of Theorem 2.3 from [91, p. 36]. □

REMARK 6.11. If $a(z) \equiv z$ in (6.32), then (6.31), (6.32) is nothing but the T-periodic boundary value problem. In this case, sequence (6.34) is reduced to the well-known T-periodic successive approximations [89],

$$x_{m+1}(t, z) := z + \int_0^t f\big(s, x_m(s, z)\big)\, \mathrm{d}s - \frac{t}{T}\int_0^T f\big(s, x_m(s, z)\big)\, \mathrm{d}s, \quad t \in [0, T].$$

REMARK 6.12. Estimate (6.35) implies that the function $t \mapsto x_m(t, z_m)$ is natural to be taken as the mth approximation of the exact solution of problem (6.31), (6.32), when $z = z_m$ is a root of the mth approximate determining equation,

$$a(z) - z = \int_0^T f\big(s, x_m(s, z)\big)\,\mathrm{d}s. \tag{6.36}$$

EXAMPLE 6.13. Let us apply the technique described above to the problem

$$\begin{aligned} &x''(t) - \frac{t}{8}x'(t) + \frac{1}{2}\big(x'(t)\big)^2 = \frac{1}{4}, \quad t \in [0, 1],\\ &x(1) = \frac{1}{2}\big(x'(0)\big)^2 + \frac{1}{16},\\ &x'(1) = -x(0) + \frac{3}{16}. \end{aligned} \tag{6.37}$$

As usual, we rewrite the second order problem (6.37) in the form

$$\begin{aligned} &x_1'(t) = x_2,\\ &x_2'(t) = \frac{1}{4} + \frac{t}{8}x_2(t) - \frac{1}{2}x_2^2(t), \quad t \in [0, 1],\\ &x_1(1) = \frac{1}{2}x_2^2(0) + \frac{1}{16},\\ &x_2(1) = -x_1(0) + \frac{3}{16}. \end{aligned} \tag{6.38}$$

Consider (6.38) in the domain

$$(t, x_1, x_2) \in [0, 1] \times D, \quad D = \left\{(x_1, x_2) \;\middle|\; |x_1| \leqslant 1, |x_2| \leqslant \frac{3}{4}\right\}. \tag{6.39}$$

It is not difficult to verify that the conditions of Theorem 6.9 are fulfilled with

$$K = \begin{pmatrix} 0 & 1 \\ 0 & \frac{7}{8} \end{pmatrix}, \qquad \gamma(x) \leqslant \begin{pmatrix} \frac{7}{16} + \frac{1}{2}x_2^2 - x_1 \\ \frac{1}{2} - x_1 - x_2 \end{pmatrix}.$$

The corresponding quantity (6.13) is estimated as

$$\delta_D(f) \leqslant \begin{pmatrix} \frac{3}{4} \\ \frac{5}{8} \end{pmatrix},$$

and K satisfies (6.14) because $r(K) = \frac{7}{8}$.

According to (6.34), we have the following formulae for $x_1 = \binom{x_{1,1}}{x_{1,2}}$:

$$x_{1,1}(t,\zeta_1,\zeta_2) = \zeta_1 + t\left(\frac{1}{2}\zeta_2^2 - \zeta_1 + \frac{1}{16}\right), \tag{6.40}$$

$$x_{1,2}(t,\zeta_1,\zeta_2) = \zeta_2 + \frac{t^2}{16}\zeta_2 - \frac{1}{16}t\zeta_2 - t\left(\zeta_1 + \zeta_2 - \frac{3}{16}\right). \tag{6.41}$$

The first approximate determining equations (6.36) have the form

$$\Delta_{1,1}(\zeta_1,\zeta_2) = 0, \qquad \Delta_{1,2}(\zeta_1,\zeta_2) = 0, \tag{6.42}$$

where

$$\Delta_{1,1}(\zeta_1,\zeta_2) = \frac{1}{2}\zeta_2^2 - \frac{47}{96}\zeta_2 - \frac{1}{2}\zeta_1 - \frac{1}{32},$$
$$\Delta_{1,2}(\zeta_1,\zeta_2) = -\frac{49}{48}\zeta_1 - \frac{33}{512} - \frac{88165}{89088}\zeta_2 + \frac{827}{5120}\zeta_2{}^2 - \frac{31}{192}\zeta_2\zeta_1 + \frac{1}{6}\zeta_1{}^2.$$

The solution, $\zeta = \binom{\zeta_1}{\zeta_2}$, of system (6.42) has the form

$$\zeta_1 = -\frac{1}{16}, \qquad \zeta_2 = 0. \tag{6.43}$$

Inserting (6.43) into (6.40) and (6.41), we obtain the first approximation

$$x_{1,1}(t) = \frac{t}{8} - \frac{1}{16}, \qquad x_{1,2}(t) = \frac{t}{4}. \tag{6.44}$$

Note that the vector function with components

$$x_1^*(t) = \frac{t^2}{8} - \frac{1}{16}, \qquad x_2^*(t) = \frac{t}{4} \tag{6.45}$$

is an exact solution of problem (6.38).

Let us construct the second approximation. By (6.34), we have

$$x_{2,1}(t,\zeta_1,\zeta_2) = \zeta_1 + \frac{1}{48}\zeta_2 t^3 - \frac{1}{2}t^2\zeta_1 + \frac{3}{32}t^2 - \frac{17}{32}t^2\zeta_2$$
$$+ \frac{49}{96}\zeta_2 t - \frac{1}{2}t\zeta_1 - \frac{1}{32}t + \frac{1}{2}t\zeta_2^2, \tag{6.46}$$

$$
\begin{aligned}
x_{2,2}(t,\zeta_1,\zeta_2) = {} & \frac{95}{512}t - \frac{31}{192}t\zeta_2\zeta_1 + z_2 + \frac{17}{768}\zeta_2 t^3 - \frac{1}{32}t^2\zeta_2 - \frac{49}{48}t\zeta_1 \\
& - \frac{1733}{5120}t\zeta_2^2 + \frac{1}{512}t^3 - \frac{3041}{3072}\zeta_2 t - \frac{1}{2560}\zeta_2^2 t^5 + \frac{1}{64}t^4\zeta_2\zeta_1 \\
& - \frac{17}{48}t^3\zeta_2\zeta_1 + \frac{1}{2}t^2\zeta_2\zeta_1 - \frac{1}{1024}t^4\zeta_2 + \frac{17}{1024}t^4\zeta_2^2 + \frac{1}{48}t^3\zeta_1 \\
& - \frac{107}{512}t^3\zeta_2^2 - \frac{1}{6}t^3\zeta_1^2 + \frac{17}{32}t^2\zeta_2^2 + \frac{1}{6}t\zeta_1^2.
\end{aligned}
\tag{6.47}
$$

It is not difficult to verify that inserting into (6.46) and (6.47) even the roots (6.43) of the *first* determining system (6.42), we arrive at the exact solution (6.45) of problem (6.38).

7. A non-linear problem with another type of separated boundary conditions

Here, we suggest a constructive scheme for the investigation of non-linear differential systems (3.3) with non-linear two-point boundary conditions of the form (2.4).

The right-hand side of the equation is supposed to be Lipschitzian in a suitable bounded domain, Ω, and the spectrum of the corresponding Lipschitz matrix is assumed to be contained inside the circle of radius less than $r \approx 3.4161/T$. Under the latter assumption, the convergence of the method is proved by using some techniques developed in [70,64] and their appropriate modifications.

It is worth mentioning that we impose the only technical restriction (7.21) on the continuous mapping $b\colon \mathbb{R}^n \to \mathbb{R}^n$, and this condition is automatically satisfied whenever the domain Ω is large enough.

7.1. *Subsidiary lemmata*

The estimates related to the successive approximation method under consideration essentially use properties of the sequence of functions $\{\alpha_{k,T}\colon\ k \geqslant 0\} \subset C([0,T])$ given by the recurrence formula (3.35):

$$
\alpha_{k+1,T}(t) = \left(1 - \frac{t}{T}\right)\int_0^t \alpha_{k,T}(s)\,\mathrm{d}s + \frac{t}{T}\int_t^T \alpha_{k,T}(s)\,\mathrm{d}s, \qquad k = 0,1,\ldots,
\tag{7.1}
$$

and $\alpha_{0,T} \equiv 1$. Let us obtain some further properties of this sequence.

LEMMA 7.1.

(1) *The functions of sequence* (7.1) *are symmetric with respect to the point $T/2$, i.e., for all $k \geqslant 0$,*

$$
\alpha_{k,T}(t) = \alpha_{k,T}(T - t), \qquad t \in [0,T];
\tag{7.2}
$$

$$
\alpha_{k,T}(T/2 - t) = \alpha_{k,T}(T/2 + t), \qquad t \in [0,T/2];
\tag{7.3}
$$

(2) *Sequence* (7.1) *can be represented alternatively as*

$$\alpha_{k+1,T}(t) = \int_0^t \alpha_{k,T}(s)\,\mathrm{d}s + \frac{t}{T}\int_t^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s \tag{7.4}$$

$$= \frac{t}{T}\int_0^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s + \bigl(1-\frac{t}{T}\bigr)\int_{T-t}^{T} \alpha_{k,T}(s)\,\mathrm{d}s \tag{7.5}$$

$$= \int_0^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s + \left(1-\frac{t}{T}\right)\int_{T-t}^{t} \alpha_{k,T}(s)\,\mathrm{d}s; \tag{7.6}$$

(3) *The relations*

$$\alpha_{k,T}(0) = \alpha_{k,T}(T) = 0; \qquad \alpha_{k,T}(t) > 0 \quad \textit{for all } t \in (0,T),$$

hold for every $k \geqslant 0$;

(4) *For every* $k \geqslant 1$, *the maximal value of* $\alpha_{k,T}(t)$ *is achieved at* $t = T/2$, *namely,*

$$\max_{t\in[0,T]} \alpha_{k,T}(t) = \alpha_{k,T}(T/2) = T^k \alpha_{k,1}(1/2). \tag{7.7}$$

PROOF. *Assertion* 1. Obviously, (7.2) holds for $k = 0$. Let us assume that (7.2) is true for some k and prove that this relation remains valid when k is replaced by $k+1$. Indeed, we have

$$\int_0^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s = \int_0^{T-t} \alpha_{k,T}(T-s)\,\mathrm{d}s = \int_t^{T} \alpha_{k,T}(s)\,\mathrm{d}s \tag{7.8}$$

and, by (7.8),

$$\int_{T-t}^{T} \alpha_{k,T}(s)\,\mathrm{d}s = \int_0^{T} \alpha_{k,T}(s)\,\mathrm{d}s - \int_0^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s = \int_0^{t} \alpha_{k,T}(s)\,\mathrm{d}s. \tag{7.9}$$

Considering (7.1), (7.8), and (7.9), we obtain

$$\alpha_{k,T}(T-t) = \left(1-\frac{T-t}{T}\right)\int_0^{T-t} \alpha_{k,T}(s)\,\mathrm{d}s + \frac{T-t}{T}\int_{T-t}^{T} \alpha_{k,T}(s)\,\mathrm{d}s$$
$$= \left(1-\frac{t}{T}\right)\int_0^{t} \alpha_{k,T}(s)\,\mathrm{d}s + \frac{t}{T}\int_t^{T} \alpha_{k,T}(s)\,\mathrm{d}s = \alpha_{k,T}(t),$$

i.e., (7.2) holds. Equality (7.3) is an immediate consequence of (7.2) with t replaced by $t + T/2$.

Assertion 2. By virtue of (7.1) and (7.9), we have

$$\alpha_{k+1,T}(t) = \int_0^t \alpha_{k,T}(s)\,\mathrm{d}s - \frac{t}{T}\int_0^t \alpha_{k,T}(s)\,\mathrm{d}s$$

$$+\frac{t}{T}\int_t^{T-t}\alpha_{k,T}(s)\,\mathrm{d}s+\frac{t}{T}\int_{T-t}^{T}\alpha_{k,T}(s)\,\mathrm{d}s$$
$$=\int_0^t\alpha_{k,T}(s)\,\mathrm{d}s+\frac{t}{T}\int_t^{T-t}\alpha_{k,T}(s)\,\mathrm{d}s,$$

i.e. (7.4) holds. To establish relation (7.5), we note that (7.5) with t replaced by $T-t$ can be rewritten as

$$\alpha_{k+1,T}(t)=\left(1-\frac{t}{T}\right)\int_0^t\alpha_{k,T}(s)\,\mathrm{d}s+\frac{t}{T}\int_t^{T}\alpha_{k,T}(s)\,\mathrm{d}s,$$

which coincides with the left-hand side of equality (7.1), i.e., with the $(k+1)$th member of the sequence defined by formula (7.1). Taking assertion 1 into account and using the fact that the change of variable $t\mapsto T-t$ is invertible, we show that representation (7.5) holds. Finally, (7.6) follows immediately when, in (7.4), we replace t by $T-t$ and take (7.2) into account.

Assertion 3. The equalities $\alpha_{k,T}(0)=\alpha_{k,T}(T)=0$ $(k=0,1,\ldots)$ follow immediately from (7.1) and (7.2). Arguing by induction and using representation (7.4) of sequence (7.1), we show that all the functions $\alpha_0,\alpha_1,\ldots$ take positive values inside the interval $(0,T)$.

Assertion 4. Differentiating (7.4) with respect to t, we obtain

$$\alpha'_{k,T}(t)=\left(1-\frac{2}{T}t\right)\alpha_{k-1,T}(t)+\frac{1}{T}\int_t^{T-t}\alpha_{k-1,T}(s)\,\mathrm{d}s, \tag{7.10}$$

whence it follows by induction that, for every k, the function $\alpha_{k,T}$ is increasing on $(0,T/2)$ and, by (7.2), is decreasing on $(T/2,T)$. Since $\alpha'_{k,T}(T/2)=0$, we see that $T/2$ is the global maximum point of $\alpha_{k,T}$, and assertion 4 is thus proved.

It is obvious that, in order to prove the second part of equality (7.7), it will suffice to establish the following relation:

$$\alpha_{m,T}(\sigma T)=T^m\alpha_{m,1}(\sigma)\quad\text{for all }\sigma\in[0,1]. \tag{7.11}$$

By (7.1), we have

$$\alpha_{m,T}(\sigma T)=(1-\sigma)\int_0^{\sigma T}\alpha_{m-1,T}(u)\,\mathrm{d}s+\sigma\int_{\sigma T}^{T}\alpha_{m-1,T}(u)\,\mathrm{d}u$$
$$=T(1-\sigma)\int_0^{\sigma}\alpha_{m-1,T}(u)\,\mathrm{d}s+T\sigma\int_{\sigma}^{1}\alpha_{m-1,T}(u)\,\mathrm{d}u$$

for all $\sigma\in[0,1]$. Introducing the mappings $A:C([0,1],\mathbb{R}^n)\to C([0,1],\mathbb{R}^n)$ and $\mathcal{S}_T:C([0,1],\mathbb{R}^n)\to C([0,T],\mathbb{R}^n)$ by the formulae

$$(Ax)(\sigma):=(1-\sigma)\int_0^{\sigma}x(u)\,\mathrm{d}u+\sigma\int_{\sigma}^{1}x(u)\,\mathrm{d}u,\quad \sigma\in[0,1], \tag{7.12}$$

and

$$(\mathcal{S}_T x)(\sigma) := x(\sigma T), \quad \sigma \in [0,1],$$

we arrive at the relations

$$\mathcal{S}_T \alpha_{m,T} = A \mathcal{S}_T \alpha_{m-1,T}, \quad m = 1, 2, \ldots,$$

whence it follows that

$$\mathcal{S}_T \alpha_{m,T} = T^m \cdot A^m \mathcal{S}_T \alpha_0 \equiv T^m \cdot A^m \mathcal{S}_T 1 \equiv T^m \cdot A^m 1. \tag{7.13}$$

On the other hand, equality (7.1) with $T = 1$ yields

$$\alpha_{m,1}(\sigma) = (1-\sigma) \int_0^\sigma \alpha_{m-1,1}(u)\,\mathrm{d}u + \sigma \int_\sigma^1 \alpha_{m-1,1}(u)\,\mathrm{d}u, \quad \sigma \in [0,1],$$

or, which is the same, $\alpha_{m,1} = A\alpha_{m-1,1}$, $m = 1, 2, \ldots$, whence

$$\alpha_{m,1} = A^m \alpha_{0,1} \equiv A^m 1, \quad m = 1, 2, \ldots. \tag{7.14}$$

Combining (7.13) and (7.14), we arrive at (7.11). The second part of (7.7) is an immediate consequence of relation (7.11). The lemma is proved. □

REMARK 7.2. Assertion 4 of Lemma 7.1 can also be derived from Corollary 10 of Rontó, Rontó, Samoilenko, and Trofimchuk [64]. Properties 1, 3, and 4 of sequence (7.1), established by Lemma 7.1, are also given by Samoilenko [85] for $T = 1$.

LEMMA 7.3. *The relations*

$$\lim_{m\to+\infty} \max_{t\in[0,T]} \frac{\alpha_{m,T}(t)}{\alpha_{m+1,T}(t)} = \lim_{m\to+\infty} \frac{\max_{t\in[0,T]} \alpha_{m,T}(t)}{\max_{t\in[0,T]} \alpha_{m+1,T}(t)}$$
$$= \lim_{m\to+\infty} \frac{\alpha_{m,T}(T/2)}{\alpha_{m+1,T}(T/2)} = \frac{1}{Tr(A)}$$

hold, where $r(A)$ is the spectral radius of operator (7.12).

PROOF. In view of (7.11), for all $m = 0, 1, 2, \ldots$,

$$\frac{\alpha_{m,T}(T/2)}{\alpha_{m+1,T}(T/2)} = \frac{\alpha_{m,1}(1/2)}{T\alpha_{m+1,1}(1/2)}.$$

By [64, Lemma 10], one has $\lim_{m\to+\infty} \sqrt[m]{\alpha_{m,1}(1/2)} = r(A)$, whereas [64, Corollary 12] implies that $\lim_{m\to+\infty} \sqrt[m]{\alpha_{m,1}(\sigma)\,/\,\alpha_{1,1}(\sigma)} = r(A)$ uniformly in $\sigma \in [0,1]$. Since

$\lim_{m\to\infty} c_m = c$ implies $\lim_{m\to\infty} \sqrt[m]{c_m} = \lim_{m\to\infty} c_{m+1}c_m^{-1} = c$, we arrive at the desired equality. □

REMARK 7.4. The value of the spectral radius $r(A)$ can be found numerically (see, e.g., [64,85]). Note that $r(A) \approx 0.292728853011 \approx 1\,/\,3.416130626393$.

Lemma 7.5 below extends Lemma 3.16.

LEMMA 7.5. *For the sequence of functions defined by relation* (7.1),[4] *given an arbitrarily small* $\varepsilon \in (0, +\infty)$, *one can specify an* $m_\varepsilon \in \mathbb{N}$ *such that*

$$\alpha_{m+1,T}(t) \leqslant T\bigl(r(A) + \varepsilon\bigr)\alpha_{m,T}(t), \quad m \geqslant m_\varepsilon, \tag{7.15}$$

and, consequently,

$$\alpha_{m+1,T}(t) \leqslant T^{m-m_\varepsilon+1}\bigl(r(A) + \varepsilon\bigr)^{m-m_\varepsilon+1}\alpha_{m_\varepsilon,T}(t), \quad m \geqslant m_\varepsilon. \tag{7.16}$$

PROOF. Estimate (7.15) is easily proved with the help of Lemma 7.3, whereas (7.16) is obtained immediately from (7.15) by the induction argument. □

The latter lemma will be used to establish error estimates for the successive approximations to be constructed below. However, when obtaining the error estimates on practice, one may want the above logic somewhat reversed. Namely, having the mth iteration (whose error, as will be shown below, is estimated with the help of the function $\alpha_{m-1,T}$), specify a (possibly negative) number ε_m such that the estimate $\alpha_{m+1,T}(t) \leqslant T(r(A) + \varepsilon_m)\alpha_{m,T}(t)$ holds for all $t \in [0, T]$. This aim can obviously be achieved by putting $\varepsilon_m := \alpha_{m+1,1}(1/2)/\alpha_{m,1}(1/2) - r(A)$, a few values of ε_m being shown in Table 1.

REMARK 7.6. Lemma 7.5 improves the result of Lemma 4 from Rontó and Mészáros [69] because the former, together with the table below, shows, in particular, that

$$\alpha_{m+1}(t) \leqslant T\bigl(r(A) + \frac{1}{1000}\bigr)\alpha_{m,T}(t)$$

for all $t \in [0, T]$ and $m \geqslant 3$, whereas $r(A) + \frac{1}{1000} \approx 0.29372885 < \frac{3}{10}$.

We also need a generalisation of Lemma 3.13.

LEMMA 7.7. *For every continuous* $x : [0, T] \to \mathbb{R}$, *the inequality*

$$\begin{aligned}&\left|\int_0^{\theta(t)} \left(x(\tau) - \frac{1}{T}\int_0^T x(s)\,\mathrm{d}s\right)\mathrm{d}\tau\right| \\ &\quad \leqslant \frac{1}{2}\alpha_{1,T}(t)\Bigl[\max_{\tau\in[0,T]} x(\tau) - \min_{\tau\in[0,T]} x(\tau)\Bigr]\end{aligned} \tag{7.17}$$

---

[4] Or, which is the same, by (7.4), (7.5), or (7.6)

Table 1

m	approximate ε_m	$r(A)+\varepsilon_m$
1	$0.406044803222 \times 10^{-1}$	$\frac{1}{3}$

10	$0.153987313839 \times 10^{-9}$	$\frac{571245741}{1951450070} \approx 0.292728853165$
11	$0.488928250983 \times 10^{-11}$	$\frac{2961468157897}{10116762073110} \approx .292728853016$
12	$-0.130772159250 \times 10^{-11}$	$\frac{5201443062517}{17768808947382} \approx 0.292728853010$
$\cdots$	$\cdots$	$\cdots$
$+\infty$	0	$r(A) \approx 0.292728853011$

holds for all $t \in [0, T]$, *where* $\theta : [0, T] \to [0, T]$ *is defined either with* $\theta(t) := t$ *or* $\theta(t) := T - t$.

PROOF. When $\theta(t) \equiv t$, the statement constitutes inequality (4) of Lemma 3 from [69]. When $\theta(t) \equiv T - t$, by the above-said, we have

$$\begin{aligned}&\left|\int_0^{T-t}\left(x(\tau) - \frac{1}{T}\int_0^T x(s)\,\mathrm{d}s\right)\mathrm{d}\tau\right| \\ &\quad \leqslant \frac{1}{2}\alpha_{1,T}(T-t)\Bigl[\max_{\tau\in[0,T]} x(\tau) - \min_{\tau\in[0,T]} x(\tau)\Bigr].\end{aligned}$$

Since, in view of Lemma 7.1 (assertion 1), we have $\alpha_{m,T}(t) = \alpha_{m,T}(T-t)$ for all $m \geqslant 0$ and $t \in [0, T]$, the latter inequality yields (7.17). □

7.2. *Successive approximations for a problem with separated boundary conditions*

We consider the two-point boundary value problem

$$x'(t) = f\bigl(t, x(t)\bigr), \quad t \in [0, T], \tag{7.18}$$

$$x(0) = b\bigl(x(T)\bigr), \tag{7.19}$$

where $f : [0, T] \times \Omega \to \mathbb{R}^n$ and $b : \Omega \to \mathbb{R}^n$ are continuous and Ω is the closure of a bounded domain. We suppose that, for every $t \in [0, T]$ fixed, f satisfies the componentwise Lipschitz condition

$$\bigl|f(t, y_1) - f(t, y_2)\bigr| \leqslant K|y_1 - y_2| \text{ for all } \{y_1, y_2\} \subset \Omega, \tag{7.20}$$

where K is a square matrix of dimension n having non-negative components. We recall that, in (7.20) and similar relations below, the signs $|\cdot|$ and $\leqslant$ are understood componentwise.

Assume that

$$\Omega(\beta) := \bigl\{x \in \mathbb{R}^n \mid H_b(x, \beta) \subset \Omega\bigr\} \neq \varnothing, \tag{7.21}$$

where

$$H_b(x, \beta) := \bigl\{u \in \mathbb{R}^n \mid \max\bigl(|u - x|, |u - b(x)|\bigr) \leqslant \beta\bigr\} \tag{7.22}$$

with $\beta := \frac{T}{4}\delta_\Omega(f)$,

$$\delta_\Omega(f) := \max_{(t,x)\in[0,T]\times\Omega} f(t, x) - \min_{(t,x)\in[0,T]\times\Omega} f(t, x), \tag{7.23}$$

and

$$r(K) < \frac{1}{Tr(A)}. \tag{7.24}$$

Recall that A is the linear operator on the space $C([0, T], \mathbb{R}^n)$ defined by formula (7.12), and $1/r(A) \approx 3.4161306$.

In connection with the study of problem (7.18), (7.19), we introduce the sequence of functions

$$\begin{aligned} x_{m+1}(t, z) := {} & \frac{t}{T}z + \left(1 - \frac{t}{T}\right)b(z) + \int_0^t f\bigl(s, x_m(s, z)\bigr)\,\mathrm{d}s \\ & - \frac{t}{T}\int_0^T f\bigl(s, x_m(s, z)\bigr)\,\mathrm{d}s, \quad m = 0, 1, 2, \ldots, \end{aligned} \tag{7.25}$$

or, which is the same,

$$\begin{aligned} x_{m+1}(t, z) := {} & \frac{t}{T}z + \left(1 - \frac{t}{T}\right)b(z) - \int_t^T f\bigl(s, x_m(s, z)\bigr)\,\mathrm{d}s \\ & + \left(1 - \frac{t}{T}\right)\int_0^T f\bigl(s, x_m(s, z)\bigr)\,\mathrm{d}s, \quad m = 0, 1, 2, \ldots, \end{aligned}$$

where

$$x_0(t,z) := \frac{t}{T}z + \left(1 - \frac{t}{T}\right)b(z) \quad \text{for all } t \in [0,T], \tag{7.26}$$

and $z = \operatorname{col}(z_1, z_2, \dots, z_n) \in \Omega(\beta)$ is a parameter.

It can be easily verified that, for every $m \in \mathbb{N} \cup \{0\}$,

$$x_m(T,z) = z \quad \text{and} \quad x_m(0,z) = b(z), \tag{7.27}$$

i.e., functions (7.25) satisfy the boundary condition (7.19) for all $z \in \Omega(\beta)$.

THEOREM 7.8. *Assume that conditions* (7.20), (7.21), *and* (7.24) *hold for the boundary value problem* (7.18), (7.19). *Then*:

(1) *Sequence* (7.25) *has a limit $x^*(\cdot,z)$ uniform in $(t,z) \in [0,T] \times \Omega(\beta)$.*

(2) *The limit function $x^*(\cdot,z)$ is a solution of the "perturbed" problem*

$$\begin{aligned} &x'(t) = f\big(t, x, (t)\big) + \frac{1}{T}\Delta(z), \quad t \in [0,T], \\ &x(0) = b\big(x(T)\big) \end{aligned} \tag{7.28}$$

such that $x^*(T,z) = z$, where

$$\Delta(z) := z - b(z) - \int_0^T f\big(s, x^*(s,z)\big)\,\mathrm{d}s. \tag{7.29}$$

(3) *Given an arbitrarily small positive ε, one can choose a number $m_\varepsilon \in \mathbb{N}$ such that, for all $m \geqslant m_\varepsilon$, the following error estimate holds*:

$$\big|x_m(t,z) - x^*(t,z)\big| \leqslant \frac{1}{2}\alpha_{m_\varepsilon,T}(t)Q_\varepsilon^{m-m_\varepsilon}(\mathbb{1}_n - Q_\varepsilon)^{-1}Q_\varepsilon\delta_\Omega(f), \tag{7.30}$$

where $\delta_\Omega(f)$ is given by the component-wise relation (7.23) *and*

$$Q_\varepsilon := T\big(r(A) + \varepsilon\big) \cdot K. \tag{7.31}$$

REMARK 7.9. The value of $\alpha_{m_\varepsilon,T}(t)$ in (7.30) can be estimated from above by using formula (7.7).

PROOF OF THEOREM 7.8. We shall prove that, under the conditions assumed, (7.25) is a Cauchy sequence in the Banach space $C([0,T],\mathbb{R}^n)$ equipped with the usual uniform norm. First, we show that $x_m(t,z) \in \Omega$ for all $(t,z) \in [0,T] \times \Omega(\beta)$ and $m \in \mathbb{N}$.

Indeed, in view of Lemma 7.7, we have

$$x_1(t,z) - \frac{t}{T}z - \left(1 - \frac{t}{T}\right)b(z) = \int_0^t \left[f(s,z) - \int_0^T f(\tau,z)\,\mathrm{d}\tau\right]\mathrm{d}s$$

and, hence,

$$\begin{aligned}\bigl|x_1(t,z) - tT^{-1}z - \bigl(1 - tT^{-1}\bigr)b(z)\bigr| &\leqslant \frac{1}{2}\alpha_{1,T}(t)\delta_\Omega(f)\\ &\leqslant \frac{T}{4}\delta_\Omega(f) \equiv \beta. \qquad (7.32)\end{aligned}$$

It is easy to see from (7.21) and (7.22) that $z \in \Omega(\beta)$ if, and only if, for every $u \in \mathbb{R}^n$, the relation $\max_{t\in[0,T]} |tT^{-1}z + (1 - tT^{-1})b(z) - u| \leqslant \beta$ implies $u \in \Omega$. Therefore, by virtue of (7.32), we conclude that $x_1(t,z) \in \Omega$ whenever $(t,z) \in [0,T] \in \Omega(\beta)$. The fact that $x_m(t,z) \in \Omega$ for all $(t,z) \in [0,T] \in \Omega(\beta)$ and $m \in \mathbb{N}$ is proved quite similarly.

Now, consider the difference

$$\begin{aligned}x_{m+1}(t,z) - x_m(t,z) = &\int_0^t \bigl[f\bigl(s, x_m(s,z)\bigr) - f\bigl(s, x_{m-1}(s,z)\bigr)\bigr]\,\mathrm{d}s\\ &- \frac{t}{T}\int_0^T \bigl[f\bigl(s, x_m(s,z)\bigr) - f\bigl(s, x_{m-1}(s,z)\bigr)\bigr]\,\mathrm{d}s \qquad (7.33)\end{aligned}$$

and introduce the notation

$$d_m(t,z) := \bigl|x_m(t,z) - x_{m-1}(t,z)\bigr|, \quad m = 1, 2, \ldots. \qquad (7.34)$$

By virtue of identity (7.33) and the Lipschitz condition (7.20), we have

$$d_{m+1}(t,z) \leqslant K\left[\left(1 - \frac{t}{T}\right)\int_0^t d_m(s,z)\,\mathrm{d}s + \frac{t}{T}\int_t^T d_m(s,z)\,\mathrm{d}s\right] \qquad (7.35)$$

for every $m \geqslant 0$. According to (7.32),

$$d_1(t,z) \equiv \bigl|x_1(t,z) - tT^{-1}z - \bigl(1 - tT^{-1}\bigr)b(z)\bigr| \leqslant \frac{1}{2}\alpha_{1,T}(t)\delta_\Omega(f). \qquad (7.36)$$

Iterating (7.35) and taking into account (7.1) and (7.36), we obtain that, for all $m \geqslant 0$, $t \in [0,T]$, and $z \in \Omega_\beta$,

$$d_{m+1}(t,z) \leqslant \frac{1}{2}K^m\alpha_{m+1,T}(t)\delta_\Omega(f). \qquad (7.37)$$

By Lemma 7.5, for an arbitrary $\varepsilon \in (0,+\infty)$, estimate (7.16) holds for the function α_{m+1} [see (7.1)] whenever m is not less than some m_ε. Fixing the number ε and combining (7.37) and (7.16), we obtain

$$d_{m+1}(t,z) \leqslant \frac{1}{2}\alpha_{m_\varepsilon,T}(t)Q_\varepsilon^{m-m_\varepsilon+1}\delta_\Omega(f) \qquad (7.38)$$

for all $t \in [0, T]$, $z \in \Omega(\beta)$, and $m \geqslant m_\varepsilon$. Therefore,

$$\begin{aligned}\left|x_{m+j}(t,z) - x_m(t,z)\right| &\leqslant \sum_{i=0}^{j-1} \left|x_{m+j-i}(t,z) - x_{m+j-i-1}(t,z)\right| \\ &= \sum_{i=1}^{j} d_{m+i}(t,z) \quad \text{by (7.38)} \\ &\leqslant \frac{1}{2}\alpha_{m_\varepsilon,T}(t) \sum_{i=0}^{j-1} Q_\varepsilon^{m-m_\varepsilon+i+1} \delta_\Omega(f) \\ &= \frac{1}{2}\alpha_{m_\varepsilon,T}(t) Q_\varepsilon^{m-m_\varepsilon} Q_\varepsilon \sum_{i=0}^{j-1} Q_\varepsilon^i \delta_\Omega(f). \qquad (7.39)\end{aligned}$$

Since ε in (7.31) can be chosen arbitrarily small, relation (7.39) together with assumption (7.24) and definition (7.31) imply $\sum_{k=0}^{+\infty} Q_\varepsilon^k = (\mathbb{1}_n - Q_\varepsilon)^{-1}$ and $\lim_{m\to\infty} Q_\varepsilon^m = 0$. This means that (7.25) is a Cauchy sequence and, hence, assertion 7.8 holds.

Passing to the limit as $m \to +\infty$ in equality (7.25), we show that the function $x^*(\cdot, z) := \lim_{m\to+\infty} x_m(\cdot, z)$ satisfies the following integral equation:

$$\begin{aligned}x(t) = \frac{t}{T}z + \left(1 - \frac{t}{T}\right)b(z) + \int_0^t f\big(\tau, x(\tau)\big)\,\mathrm{d}\tau \\ - \frac{t}{T}\int_0^T f\big(\tau, x(\tau)\big)\,\mathrm{d}\tau. \qquad (7.40)\end{aligned}$$

It follows from (7.40) and (7.27) that $x^*(\cdot, z)$ satisfies the two-point boundary condition (7.19). It is also obvious from (7.40) that $x^*(T, z) = z$, which means that $x^*(\cdot, z)$ is a solution of problem (7.28), i.e., assertion 7.8 holds. Estimate (7.30) of assertion 7.8 is an immediate consequence of (7.39). ☐

REMARK 7.10. In a number of earlier works in this area (see, e.g., [70] for a survey), conditions of the form $r(K) < cT^{-1}$ with $2 < c < 1/r(A)$ were assumed instead of (7.24).

REMARK 7.11. Depending on the form of a particular boundary value problem, one may want to choose a different starting approximation, x_0, for the iteration process (7.25). For instance, if a "slowly varying" solution is expected, one may put $x_0(t, z) := z$, which was often done in the earlier works on the numerical-analytic method. In the latter case, on the assumption that

$$z \in \left\{u \in \mathbb{R}^n \;\middle|\; B\left(u, \frac{T}{4}\delta_\Omega(f)\right) \subset \Omega\right\} \neq \varnothing,$$

the convergence of sequence (7.25) as well as estimate (7.30) of Theorem 7.8 can easily be proved, e.g., by using Lemma 4 from [70, p. 384]. For this purpose, it suffices to replace (7.38) by the inequality

$$d_{m+1}(t,z) \leqslant \alpha_{m_\varepsilon,T}(t)\left[\frac{1}{2}Q_\varepsilon^{m-m_\varepsilon+1}\delta_\Omega(f) + K\,Q_\varepsilon^{m-m_\varepsilon}\big|b(z)+z\big|\right],$$

put $a_m := T\alpha_{m,1}(\frac{1}{2})K^{m-1}\delta_\Omega(f)$, $b_m := T\alpha_{m-1,1}(\frac{1}{2})K^{m-1}|b(z)+z|$, $u_m := \operatorname{col}(a_m, b_m)$ and $\phi_1(t) := \phi_2(t) := 1$, and notice that, for an arbitrary fixed positive ε and all m greater than some $m_\varepsilon \in \mathbb{N}$, estimate (7.15) of Lemma 7.5 implies the component-wise relation $u_{m+1} \leqslant T[r(A)+\varepsilon]\operatorname{diag}(K,K)u_m$. Then, similarly to [70, p. 385], assumption (7.24) implies that $\lim_{m\to+\infty} d_m(t,z) = 0$ uniformly in $(t,z) \in [0,T]\times\Omega(\beta)$, which, by (7.34), means that (7.25) is a Cauchy sequence.

Now we show that, in view of Theorem 7.8, the boundary value problem (7.18), (7.19) can be formally interpreted as a family of initial value problems for differential equations with "additively forced" right-hand side members. Namely, consider the Cauchy problem

$$x(T) = z \tag{7.41}$$

for the system

$$x'(t) = f\big(t, x(t)\big) + \mu, \quad t \in [0,T], \tag{7.42}$$

where $\mu \in \mathbb{R}^n$ and $z \in \Omega(\beta)$ are parameters.

THEOREM 7.12. *Under the conditions of Theorem* 7.8, *the solution of the initial value problem* (7.42) *satisfies the two-point condition* (7.19) *if, and only if* $\mu = \frac{1}{T}\Delta(z)$, *where* $\Delta : \Omega(\beta) \to \mathbb{R}^n$ *is the mapping defined by* (7.29).

REMARK 7.13. It is easy to show that the Lipschitz condition (7.20) implies that (7.42) has a unique solution for all $(\mu, z) \in \mathbb{R}^n \times \Omega(\beta)$.

PROOF OF THEOREM 7.12. It follows from the proof of Theorem 7.8 that, for every fixed $z \in \Omega(\beta)$, the function

$$x = x^*(\cdot, z) = \lim_{m\to+\infty} x_m(\cdot, z) \tag{7.43}$$

[see (7.25)] satisfies the integral equation (7.40). This implies immediately that (7.43) is the unique (see Remark 7.13) solution of the initial value problem (7.41) for the system

$$x'(t) = f\big(t, x(t)\big) + \frac{1}{T}\Delta(z), \quad t \in [0,T], \tag{7.44}$$

and, in addition, (7.43) satisfies the two-point condition (7.19). Since (7.44) coincides with problem (7.42) corresponding to $\mu = \frac{1}{T}\Delta(z)$. The fact that function (7.43) is not solution of (7.42) for any other value of μ, is obvious, e.g., from Eq. (7.40). □

COROLLARY 7.14. *Under the conditions of Theorem* 7.8, *the limit function* (7.43) *of sequence* (7.25) *is a solution of the two-point boundary value problem* (7.18), (7.19) *if, and only if the parameter* $z \in \Omega(\beta)$ *involved in* (7.25) *and* (7.43) *satisfies the following "determining equation"*:

$$z - b(z) = \int_0^T f\bigl(s, x^*(s, z)\bigr)\,\mathrm{d}s. \tag{7.45}$$

In Corollary 7.14, the parameter z can be interpreted as the value at $t = T$ of a possible solution of problem (7.18), (7.19).

PROOF. It suffices to apply Theorem 7.12 and notice that the differential equation in (7.44) coincides with (7.18) if, and only if z satisfies $\Delta(z) = 0$, i.e., when relation (7.45) holds. □

REMARK 7.15. On practise, it is natural to fix some natural m and consider the "approximate determining equation"

$$z - b(z) = \int_0^T f\bigl(s, x_m(s, z)\bigr)\,\mathrm{d}s. \tag{7.46}$$

In case Eq. (7.46) has an isolated root, say $z = z_m$, in some open subdomain of $\Omega(\beta)$, one can prove that, under certain additional conditions, the exact determining equation (7.45) is also solvable and, hence, the two-point problem (7.18), (7.19) has a solution x satisfying $x(T) \in \Omega(\beta)$; in addition, the function

$$\xi_m(t) := x_m(t, z_m), \quad t \in [0, T], \tag{7.47}$$

can be regarded as the "mth approximation" to the solution mentioned [see estimate (7.30)]. For that purpose, one can use some topological degree techniques (cf. Theorem 3.1 in [70, p. 43]) or the methods for the approximate solution of non-linear equations in Banach spaces extensively developed in the book of Krasnoselskii et al. [37] (see, e.g., Theorem 19.2 in [37, p. 281]). Here, we do not consider this problem in more detail.

We apply the above techniques to the following

EXAMPLE 7.16. Consider the two-point problem

$$\begin{aligned} & x''(t) - \frac{t}{8}x'(t) + \frac{1}{2}\bigl(x'(t)\bigr)^2 + \frac{1}{2}x(t) = \frac{9}{32} + \frac{t^2}{16}, \quad t \in [0, 1], \\ & x(0) = \bigl(x'(1)\bigr)^2, \\ & x'(0) = x'(1) - x(1) - \frac{1}{16}. \end{aligned} \tag{7.48}$$

By setting $x_1 := x$ and $x_2 := x'$, system (7.48) is rewritten as

$$\begin{aligned} x_1'(t) &= x_2(t), \\ x_2'(t) &= \frac{9}{32} + \frac{t^2}{16} + \frac{t}{8} x_2(t) - \frac{1}{2}\bigl(x_2(t)\bigr)^2 - \frac{1}{2} x_1(t), \\ x_1(0) &= \bigl(x_2(1)\bigr)^2, \\ x_2(0) &= x_2(1) - x_1(1) - \frac{1}{16}. \end{aligned} \tag{7.49}$$

Let us consider the first order problem (7.49) in the domain $(t, x_1, x_2) \in [0,1] \times \Omega$ with $\Omega := \{(x_1, x_2) \mid |x_1| \leqslant 1, |x_2| \leqslant \frac{3}{4}\}$. It is not difficult to verify that the corresponding quantity (7.23) is estimated as $\delta_\Omega(f) \leqslant \operatorname{col}(\frac{3}{2}, \frac{5}{4})$, and (7.20) holds with $\beta = \frac{1}{4}\delta_\Omega(f) \leqslant \operatorname{col}(\frac{3}{8}, \frac{5}{16})$, because $x \in \Omega(\beta)$ whenever $|x|$ is small enough. Condition (7.21) is satisfied with $K := \bigl(\begin{smallmatrix} 0 & 1 \\ \frac{1}{2} & \frac{1}{8} \end{smallmatrix}\bigr)$ and, by Remark 7.4, the spectral radius of the matrix K satisfies inequality (7.24): $r(K) = \frac{7+\sqrt{177}}{16} \approx 1.269 < 1/r(A)$.

Let us see how the “zero approximation” (in the sense of Remark 7.15), behaves. According to (7.26), we have

$$\begin{aligned} x_{0,1}(t,z) &= \bigl(z_1 - {z_2}^2\bigr)t + {z_2}^2, \\ x_{0,2}(t,z) &= \left(z_1 + \frac{1}{16}\right)t + z_2 - z_1 - \frac{1}{16}, \end{aligned} \tag{7.50}$$

where $x_k := \operatorname{col}(x_{k,1},\ x_{k,2})$ for $k = 0, 1, \ldots$. The corresponding system of approximate determining equations is written as

$$\begin{aligned} &\frac{3}{2} z_1 - {z_2}^2 + \frac{1}{32} - z_2 = 0, \\ &-\frac{3}{32} z_2 + \frac{31}{24} z_1 - \frac{365}{1536} + \frac{1}{6} {z_1}^2 - \frac{1}{2} z_2 z_1 + \frac{3}{4} {z_2}^2 = 0. \end{aligned}$$

It has a positive solution

$$z_1 \approx 0.1801357504, \qquad z_2 \approx 0.2425992362, \tag{7.51}$$

which, substituted into (7.50) according to (7.47), yields the zeroth approximation to the solution of problem (7.48):

$$\xi_0(t) \approx 0.1212813610 \cdot t + 0.05885438940, \quad t \in [0,1]. \tag{7.52}$$

Let us construct the first and the second approximations. According to formula (7.25), we have

$$x_{1,1}(t,z) = \frac{1}{2}\left(z_1 + \frac{1}{16}\right)t^2 + \left(\frac{1}{2} z_1 - {z_2}^2 - \frac{1}{32}\right)t + {z_2}^2, \tag{7.53}$$

and

$$
\begin{aligned}
x_{1,2}(t,z) = {} & \left(\frac{3}{128} - \frac{1}{6}\left(z_1 + \frac{1}{16}\right)^2 + \frac{1}{24}z_1\right)t^3 \\
& + \left(\frac{1}{16}z_2 - \frac{5}{16}z_1 - \frac{1}{256} - \frac{1}{2}\left(z_2 - z_1 - \frac{1}{16}\right)\left(z_1 + \frac{1}{16}\right)\right. \\
& \left. + \frac{1}{4}{z_2}^2\right)t^2 + \left[-\frac{1}{16}z_2 + \frac{61}{48}z_1 + \frac{11}{256} - \frac{1}{4}{z_2}^2 + \frac{1}{6}\left(z_1 + \frac{1}{16}\right)^2\right. \\
& \left. + \frac{1}{2}\left(z_2 - z_1 - \frac{1}{16}\right)\left(z_1 + \frac{1}{16}\right)\right]t + z_2 - z_1 - \frac{1}{16}.
\end{aligned}
$$

The corresponding two approximate determining equations (7.46) are

$$
\frac{281}{192}z_1 - \frac{23}{24}{z_2}^2 + \frac{75}{2048} + \frac{1}{24}{z_1}^2 - \frac{191}{192}z_2 - \frac{1}{12}z_2 z_1 = 0 \tag{7.54}
$$

and

$$
\begin{aligned}
& \frac{5524531}{4423680}z_1 - \frac{32309}{327680}z_2 + \frac{18407}{24576}{z_2}^2 + \frac{98797}{645120}{z_1}^2 - \frac{28847}{61440}z_2 z_1 \\
& \quad + \frac{1}{945}{z_1}^4 - \frac{1}{240}{z_2}^3 z_1 + \frac{1}{960}{z_2}^4 - \frac{53}{1280}{z_2}^3 + \frac{2467}{120960}{z_1}^3 + \frac{1}{160}{z_2}^2{z_1}^2 \\
& \quad - \frac{1}{240}{z_1}^3 z_2 - \frac{61}{768}z_2{z_1}^2 + \frac{391}{3840}{z_2}^2 z_1 = \frac{16965793}{70778880},
\end{aligned} \tag{7.55}
$$

respectively. Computing a non-negative solution of (7.54), (7.55), we obtain

$$
z_1 \approx 0.1875156187, \qquad z_2 \approx 0.2500152909, \tag{7.56}
$$

and, inserting (7.56) into (7.53), we arrive at the first approximation:

$$
\xi_1(t) \approx 0.06250764568 + 0.163710^{-6}t + 0.1250078094t^2, \quad t \in [0,1]. \tag{7.57}
$$

In a similar manner, one can establish that the second approximate system of determining equations has a positive solution

$$
z_1 \approx 0.1874363008, \qquad z_2 \approx 0.2499449264 \tag{7.58}
$$

and, by (7.47) and (7.58), the corresponding function of the second approximation has the form

$$
\begin{aligned}
\xi_2(t) \approx {} & 0.06247246623 - 0.2235410^{-5}t + 0.005208996698t^4 \\
& - 0.01041383249t^3 + 0.1301709057t^2, \quad t \in [0,1].
\end{aligned} \tag{7.59}
$$

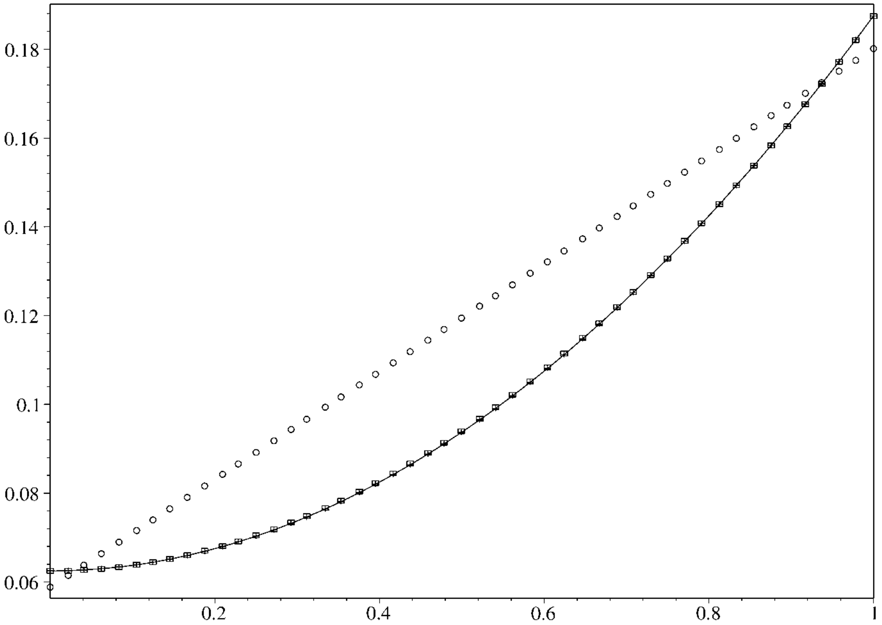

Fig. 6. The exact solution of problem (7.48) and functions (7.52), (7.57), and (7.59).

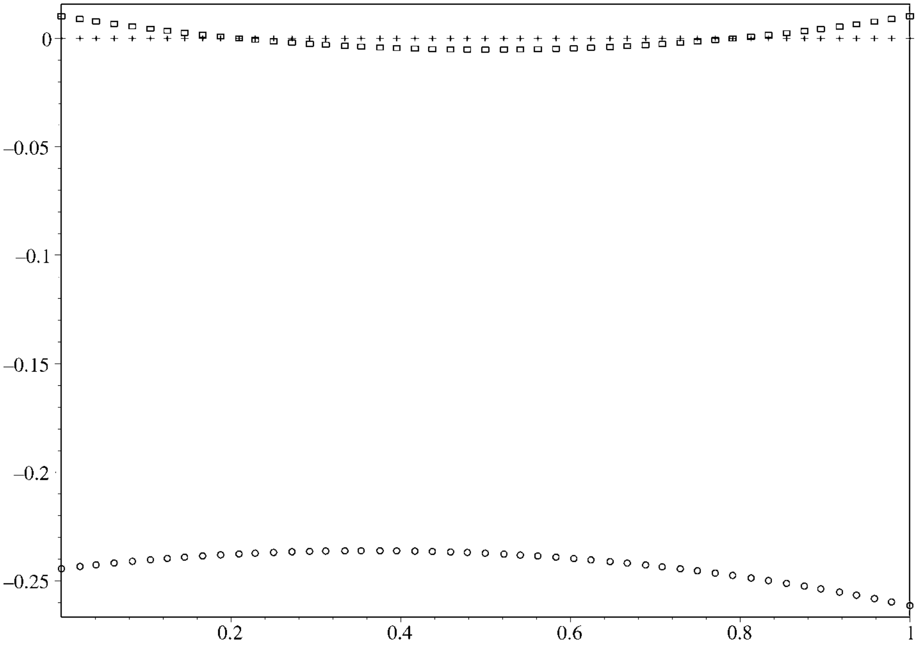

Fig. 7. Functions (7.61) for $k = 0, 1, 2$.

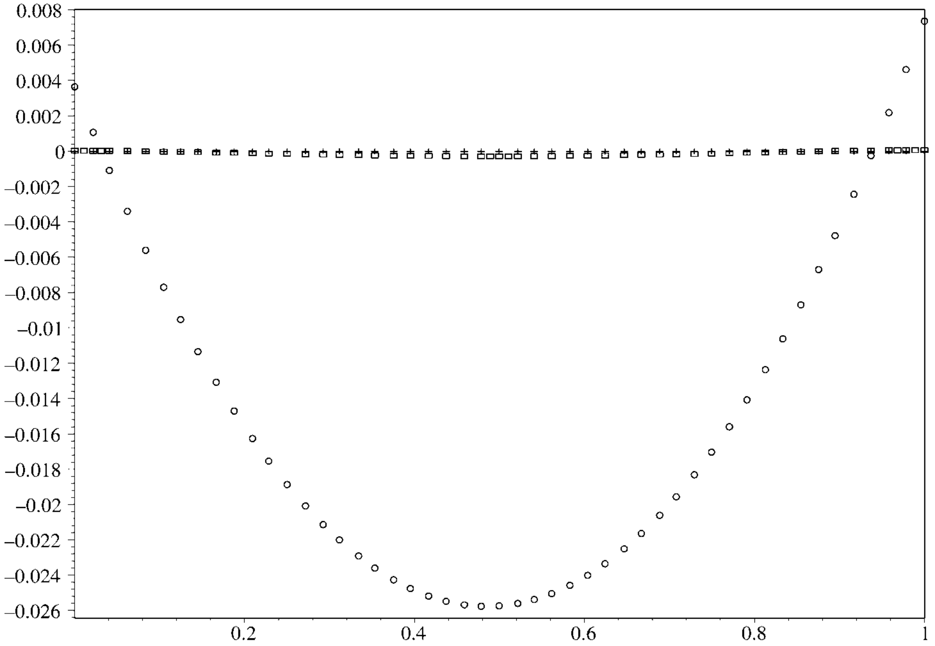

Fig. 8. The difference between the exact solution (7.60) of problem (7.48) and functions (7.52), (7.57), and (7.59).

Note that the two-point problem (7.48) has a solution

$$x(t) = \frac{t^2}{8} + \frac{1}{16}, \quad t \in [0, 1], \tag{7.60}$$

which, as is seen from Fig. 6, is well enough approximated by functions (7.52), (7.57), and (7.59) constructed above according to formula (7.47).

The functions

$$t \mapsto \xi_k''(t) - \frac{t}{8}\xi_k'(t) + \frac{1}{2}\bigl(\xi_k'(t)\bigr)^2 + \frac{1}{2}x\xi_k(t) - \frac{t^2}{16} - \frac{9}{32}, \quad k = 0, 1, 2, \tag{7.61}$$

obtained as a result of substitution of functions (7.52), (7.57), and (7.59) into the given differential equation, are plotted on Fig. 7, and the error of the approximate solutions with respect to function (7.60) is illustrated by Fig. 8. On all the figures, the symbols “circle”, “cross”, and “box” indicate the curves related to the zero, first, and second approximations, respectively. The graph of the exact solution (7.60) of problem (7.48) is drawn with the solid line [which, in fact, almost coincides with the graphs of functions (7.57) and (7.59)].

The computation shows that, e.g., function (7.59) satisfies the differential equation in (7.48) “up to 0.01” and differs from the exact solution (7.60) at most by 0.001.

8. Parametrisation method for three-point boundary value problems

Here, a three-point boundary-value problem for a system of non-linear differential equations is transformed to certain family of two-point problems the solutions of which are investigated by using successive approximation techniques.

Numerous approaches to investigation of boundary value problems with unknown parameters are available. Various iteration methods are used for such problems in the papers of Goma [26,25,27], Hosabekov [30], Kurpel′ and Marusjak [41]. In the works of Akhmedov, Svarichevskaya, and Yagubov [3], Luchka [45], Luchka and Zakhari͡ĭchenko [46], Samoilenko, Luchka, and Listopadova [93,94], the method of averaging of functional corrections and other projection-iterative methods are developed. Estimates of the number of solutions of certain singular two-point problems with parameters were obtained by Fečkan [19,20] by using the Nielsen fixed point theory. Various versions of the continuation method are studied, e.g., in the book of Gaines and Mawhin [24]. The are many works where different kinds of two-point and multipoint boundary value problems are studied by using numerical methods (see, e.g., the books of Ascher, Mattheij, and Russell [6], Keller [35] and the bibliography given therein for a survey).

It is important to note that the majority of works dealing with the numerical finding of solutions of boundary value problems are based upon the shooting method (see, e.g., [35, 6,10,1]). In particular, in the book of Keller [35], the two-point problem

$$y'(x) = f(x, y(x), \lambda_1, \lambda_2, \dots, \lambda_m), \quad x \in [a, b], \tag{8.1}$$

$$Ay(a) + By(b) = \gamma, \tag{8.2}$$

is considered, where $y : [a, b] \to \mathbb{R}^n$, A and B are given matrices of dimension $(m+n) \times n$, and λ_1, λ_2, …, λ_m are unknown parameters. Recall that the idea of the shooting method for the two-point problem (8.1), (8.2) is to replace it by the Cauchy problem for the same equation subjected to the initial conditions

$$y(a) = s. \tag{8.3}$$

In this case, the solution $y(\cdot, s, \lambda)$ of problem (8.1), (8.3) contains the unknown parameters $\lambda = \operatorname{col}(\lambda_1, \lambda_2, \dots, \lambda_m)$ and $s = \operatorname{col}(s_1, s_2, \dots, s_n)$ whose values are to be determined from the system of $n + m$ equations

$$Ay(a, s, \lambda) + By(b, s, \lambda) = \gamma. \tag{8.4}$$

It is then stated that the two-point problem (8.1), (8.2) has the same number of solutions as the system of numerical equations (8.4).

The main complication in this approach obviously lies in the numerical construction and investigation of system (8.4), which is possible only if the initial value problems (8.1), (8.3) for arbitrary values of λ and s have a unique solution *well-defined on the entire interval* $[a, b]$. In this relation, it is usually assumed that the function f involved in the right-hand side of (8.1) is continuous on the entire space and satisfies the Lipschitz condition with respect to the second argument on the entire $\mathbb{R}^n$.

The rigorous investigation of boundary value problems by using numerical methods tends to avoid the case where the range of solutions in question is restricted to a certain given (possibly, bounded) closed $D \subset \mathbb{R}^n$ and, correspondingly, one or another regularity assumption is imposed on the function f on the set $[a, b] \times D \times \mathbb{R}^m$ only. For example, in the case of the scalar two-point boundary value problem (8.2) for the equation

$$x'(t) = \big(x(t)\big)^2, \quad t \in [a, b], \tag{8.5}$$

the global Lipschitz condition for the right-hand side of (8.5) is obviously not satisfied. The local solution of the corresponding Cauchy problem (8.5), (8.3) has the form

$$x(t, s) = -\frac{1}{t - s^{-1} - a}, \quad t \in [a, b], \tag{8.6}$$

where s is a real parameter. It is clear from (8.6) that if $0 \leqslant s^{-1} \leqslant b - a$ then the solution of the initial value problem (8.5), (8.3) is undefined on the entire interval $[a, b]$ and, therefore, it does not make sense even to construct Eq. (8.4), not talking of its solution.

In many cases, the complications indicated can be overcome by using the approach of [89,70,60,66].

8.1. *Problem setting*

Let us consider the problem on finding a solution of the differential system (2.1) satisfying the three-point non-separated linear boundary conditions

$$Ax(0) + Bx(\xi) + x(T) = d, \tag{8.7}$$

where $f : [0, T] \times D \to \mathbb{R}^n$, D is the closure of a bounded domain in $\mathbb{R}^n$, $\{A, B\} \subset \mathrm{GL}_n(\mathbb{R})$, and $\xi \in (0, T)$ is given. It is easy to see that the tree-point boundary condition (2.5) with a non-singular matrix C can be brought to form (8.7) (it suffices to replace A, B, and d in (8.7) by $C^{-1}A$, $C^{-1}B$, and $C^{-1}d$, respectively). Conditions (8.7) are non-separated unless the matrices A and B are both equal to zero.

Here we show an approach to the investigation of problem (2.1), (8.7), which is based upon artificial introduction of a suitable number of parameters into the boundary conditions and allows one to construct approximate solutions in an analytic form.

We assume that the function $f : [0, T] \times D \to \mathbb{R}^n$ is continuous and, in the second variable, satisfies the Lipschitz condition (3.5) with a certain n-dimensional square matrix K with non-negative elements.

We restrict our consideration by the class of differential systems (2.1) for which the spectral radius $r(K)$ of the non-negative matrix K appearing in the Lipschitz condition (3.5) satisfies inequality (6.14).

8.2. *Transformation to a two-point problem with a parameter in boundary conditions*

Let us replace formally the value of the unknown solution of problem (2.1), (8.7) at the point ξ by the n-dimensional vector of parameters $(\lambda_k)_{k=1}^n$ that varies in a certain set $\Lambda \subset D$:

$$x(\xi) = \lambda. \tag{8.8}$$

Every function x satisfying relations (8.8) and (8.7) obviously has the property

$$Ax(0) + x(T) = d - B\lambda. \tag{8.9}$$

Let us consider problem (2.1), (8.9), in which the two-point boundary condition (8.9) contains an unknown parameter $\lambda \in \Lambda$.

REMARK 8.1. The set of solutions of the original three-point problem (2.1), (8.7), clearly, coincides with the set of those solutions of the two-point problem (2.1), (8.9) for which the parameter λ satisfies the additional condition (8.8).

For any $\{z, \lambda\} \subset \mathbb{R}^n$, we put

$$\beta(z, \lambda) := \frac{T}{4}\delta_D(f) + \left|d - B\lambda - (A + \mathbb{1}_n)z\right|, \tag{8.10}$$

where $\mathbb{1}_n$ is the unit matrix of dimension n and $\delta_D(f)$ is defined by equality (6.13). We shall assume in the sequel that the set $\Gamma \subseteq D$ given by the formula

$$\Gamma := \left\{z \in D\colon\ B\big(z, \beta(z, \lambda)\big) \subset D \text{ for all } \lambda \in \Lambda\right\} \tag{8.11}$$

is non-empty: $\Gamma \neq \varnothing$. Recall that, here and above, notation (12) of Section 1 is used.

With the parametrised problem (2.1), (8.9), we associate the sequence of functions

$$\begin{aligned} x_{m+1}(t, z, \lambda) := z &+ \int_0^t f\big(s, x_m(s, z, \lambda)\big)\,\mathrm{d}s - tT^{-1}\int_0^T f\big(s, x_m(s, z, \lambda)\big)\,\mathrm{d}s \\ &+ tT^{-1}[d - B\lambda - Az - z], \end{aligned} \tag{8.12}$$

where $\lambda \in \Lambda$, $z \in \Gamma$, $m = 0, 1, 2, \ldots$, $x_0(t, z, \lambda) \equiv z$. It is easy to see that $x_m(0, z, \lambda) = z$ for any $m \geqslant 0$, $\lambda \in \Lambda$, and $z \in \Gamma$ and, moreover,

$$x_m(T, z, \lambda) = d - B\lambda - Az, \tag{8.13}$$

i.e., function (8.12) satisfies the two-point condition (8.9).

REMARK 8.2. The two-point condition (8.9) obviously explicitly only p parameters among λ_1, λ_2, $\ldots$, λ_n, where $p = \operatorname{rank} B$. Therefore, relation (8.8), according to which the three-point condition (8.7) is replaced by the two-point boundary condition (8.9), can be replaced by the relation

$$Bx(\xi) = B\lambda. \tag{8.14}$$

In other words, it is sufficient to consider only those solutions of the two-point problem (2.1), (8.9), for which the additional condition (8.14) is satisfied. In this case, one completely excludes from consideration the $n - p$ parameters the values of which one need not to determine. If $p = n$ (i.e., $\det B \neq 0$), then conditions (8.14) and (8.8) have the same meaning.

One could also construct a similar scheme by replacing the three-point condition (8.7) by the condition

$$Ax(0) + x(T) = d - \mu \tag{8.15}$$

and seeking for those solutions x of the two-point problem (2.1), (8.15), for which $Bx(\xi) = \mu$.

8.3. *Convergence of successive approximations*

Let us present conditions sufficient for the uniform convergence of the recurrence sequence (8.12) and establish the relation between its limit and the sets of solutions of problems (2.1), (8.7) and (2.1), (8.9).

THEOREM 8.3. *Assume that the continuous function* $f : [0, T] \times D \to \mathbb{R}^n$ *satisfies condition* (3.5) *with the matrix* K *possessing property* (6.14). *Moreover, let the matrices* A, B *and the vector* d *be such that* $\Gamma \neq \varnothing$.

Then:

(1) *Sequence* (8.12) *converges uniformly in* $t \in [0, T]$ *for all* $(z, \lambda) \in \Gamma \times \Lambda$;

(2) *For any* $(z, \lambda) \in \Gamma \times \Lambda$, *the limit function*

$$x^*(t, z, \lambda) := \lim_{m\to+\infty} x_m(t, z, \lambda) \tag{8.16}$$

of sequence (8.12) *is the unique solution of the integral equation*

$$\begin{aligned} x(t) := z + \int_0^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s - tT^{-1}\int_0^T f\bigl(s, x(s)\bigr)\,\mathrm{d}s \\ + tT^{-1}[d - B\lambda - Az - z], \quad t \in [0, T], \end{aligned} \tag{8.17}$$

or, which is the same, of the integro-differential equation

$$x'(t) = f\bigl(t, x(t)\bigr) + T^{-1}\Delta(z, \lambda), \quad t \in [0, T], \tag{8.18}$$

where

$$\Delta(z,\lambda) := d - B\lambda - Az - z - \int_0^T f\bigl(s, x^*(s,z,\lambda)\bigr)\,\mathrm{d}s. \tag{8.19}$$

For $(z,\lambda) \in \Gamma \times \Lambda$, *this solution satisfies the boundary conditions* (8.9);

(3) *For all* $(t,z,\lambda) \in [0,T] \times \Gamma \times \Lambda$, *the estimate*

$$\bigl|x^*(t,z,\lambda) - x_m(t,z,\lambda)\bigr| \leqslant h(t,z,\lambda), \tag{8.20}$$

is true, where

$$h(t,z,\lambda) := \frac{20t}{9}\left(1 - \frac{t}{T}\right) Q^m (\mathbb{1}_n - Q)^{-1}\bigl[\delta_D(f) + K|d - B\lambda - Az - z|\bigr]$$

and $Q := \frac{3T}{10}K$.

Proof. Let us show that sequence (8.12) is a Cauchy sequence in the Banach space $C([0,T],\mathbb{R}^n)$. Let us first prove that the values of each of the functions (8.12) for all $(z,\lambda) \in \Gamma \times \Lambda$ are contained in D. By Lemma 7.7, for any continuous $x : [0,T] \to \mathbb{R}^n$, the estimate

$$\left|\int_0^t \left(x(\tau) - \frac{1}{T}\int_0^T x(s)\,\mathrm{d}s\right)\mathrm{d}\tau\right| \leqslant \frac{1}{2}\alpha_{1,T}(t)\Bigl[\max_{\tau\in[0,T]} x(\tau) - \min_{\tau\in[0,T]} x(\tau)\Bigr]$$

is true, where the function $\alpha_{1,T}$ has form (3.34). It follows from Lemma 7.1 that $\max_{t\in[0,T]}\alpha_{1,T}(t) = T/2$. Therefore, for $m = 0$, relation (8.12), in view of (8.10), implies that

$$\bigl|x_1(t,z,\lambda) - z\bigr| \leqslant \frac{1}{2}\alpha_{1,T}(t)\delta_D(f) + |d - B\lambda - z - Az| \leqslant \beta(z,\lambda),$$

for any $(t,z,\lambda) \in [0,T] \times \Gamma \times \Lambda$. Here the value $\delta_D(f)$ is given by formula (6.13). Therefore, in view of (8.11), it follows that $x_m(t,z,\lambda) \in D$ for all such (t,z,λ) and any $m = 0,1,2,\ldots$. Arguing similarly to the proof of [71, Theorem 1], one can show that, for all $m \geqslant 0$, $j \geqslant 0$ and $(t,z,\lambda) \in [0,T] \times \Gamma \times \Lambda$

$$\begin{aligned}\bigl|x_{m+j}(t,z,\lambda) - x_m(t,z,\lambda)\bigr| \leqslant \frac{10t}{9}\alpha_{1,T}(t)Q^m\Biggl[\frac{1}{2}\sum_{i=0}^{j-1} Q^i\delta_D(f) \\ + K\sum_{i=0}^{j-1} Q^{i-1}|d - B\lambda - z - Az|\Biggr].\end{aligned} \tag{8.21}$$

Since, by (6.14), $\lim_{m\to+\infty} Q^m = 0$ and $\sum_{i=0}^{+\infty} Q^i = (\mathbb{1}_n - Q)^{-1}$, it is obvious from (8.21) that (8.12) is a Cauchy sequence in the uniform norm. Passing to the limit when j

tends to $+\infty$ in (8.21), we obtain that the uniform limit (8.16) of sequence (8.12) satisfies inequality (8.20). Passing to the limit as $m \to +\infty$ in (8.12) and (8.13), we conclude that function (8.16) satisfies Eqs. (8.17), (8.18) and condition (8.9). ☐

REMARK 8.4. It is clear from the form of Eq. (8.17) that, under assumptions of Theorem 8.3, its unique solution (8.16) for all $(z, \lambda) \in \Gamma \times \Lambda$ satisfies condition

$$x^*(0, z, \lambda) = z. \tag{8.22}$$

REMARK 8.5. In some papers (e.g., in [41,100,101]), parametrised problems of type (2.1), (8.9) are studied by means of construction of two separate iteration processes for the unknown function and the vector of parameters.

The form of the "perturbed" equation (8.18) suggests the idea that the parametrised boundary value problem (2.1), (8.9) might be interpreted as the family of the Cauchy problems

$$x(0) = z \tag{8.23}$$

for the differential equations of the form

$$x'(t) = f\bigl(t, x(t)\bigr) + \mu, \quad t \in [0, T], \tag{8.24}$$

where the vector of parameters μ takes values in a suitable set. More precisely, the following statement holds.

THEOREM 8.6. *Let conditions of Theorem* 8.3 *be satisfied and let* $(z, \lambda) \in \Gamma \times \Lambda$ *and* $\mu \in \mathbb{R}^n$. *Then a solution of the Cauchy problem* (8.24), (8.23) *satisfies the two-point boundary conditions* (8.9) *if and only if the parameter* μ *in* (8.24) *is given by the equation*

$$\mu = \frac{1}{T}\Delta(z, \lambda), \tag{8.25}$$

where $\Delta : \Gamma \times \Lambda \to \mathbb{R}^n$ *is the function defined by formula* (8.19).

REMARK 8.7. It follows from Theorem 8.3 that, under the conditions indicated above, for any $(z, \lambda) \in \Gamma \times \Lambda$, there exists a limit function (8.16) of the recurrence sequence (8.12) and, therefore, mapping (8.19) is well-defined.

PROOF OF THEOREM 8.6. *Sufficiency.* Let us put $\mu = T^{-1}\Delta(z, \lambda)$, in (8.24), where $z \in \Gamma$ and $\lambda \in \Lambda$ are some fixed vectors, and Δ is given b formula (8.19). According to Remark 8.7, the expression $\Delta(z, \lambda)$ makes sense for all $(z, \lambda) \in \Gamma \times \Lambda$. Theorem 8.3 implies that, for the given z and λ, the uniform limit (8.16) of the corresponding sequence (8.12) coincides with the unique solution of the two-point problem (8.18), (8.9). As indicated in Remark 8.4, this function also satisfies the initial condition (8.22), i.e., is a solution of the Cauchy problem (8.24), (8.23) corresponding to the value (8.25) of the parameter μ.

Necessity. Let $z \in \Gamma$, $\lambda \in \Lambda$, and $\bar{\mu} \in \mathbb{R}^n$ be arbitrary vectors, and $\bar{x} : [0, T] \to \mathbb{R}^n$ be a solution of the Cauchy problem (8.23) for the equation

$$x'(t) = f\big(t, x(t)\big) + \bar{\mu}, \quad t \in [0, T], \tag{8.26}$$

satisfying, for the given value of λ, the two-point condition (8.9). Assume that there exists another value $\bar{\bar{\mu}}$, of the parameter μ, for which a certain solution $\bar{\bar{x}}$ of problem (8.23) for the equation

$$x'(t) = f\big(t, x(t)\big) + \bar{\bar{\mu}}, \quad t \in [0, T], \tag{8.27}$$

satisfies the two-point condition (8.9). It is obvious from (8.23), (8.26), and (8.27) that the functions $\bar{x}$ and $\bar{\bar{x}}$ satisfy the integral equations

$$\bar{x}(t) = z + \int_0^t f\big(s, \bar{x}(s)\big)\,\mathrm{d}s + \bar{\mu}t, \quad t \in [0, T], \tag{8.28}$$

and

$$\bar{\bar{x}}(t) = z + \int_0^t f\big(s, \bar{\bar{x}}(s)\big)\,\mathrm{d}s + \bar{\bar{\mu}}t, \quad t \in [0, T], \tag{8.29}$$

respectively. For $t = T$, relations (8.28), (8.29) yield

$$T\bar{\mu} = \bar{x}(T) - z - \int_0^T f\big(s, \bar{x}(s)\big)\,\mathrm{d}s \tag{8.30}$$

and

$$T\bar{\bar{\mu}} = \bar{\bar{x}}(T) - z - \int_0^T f\big(s, \bar{\bar{x}}(s)\big)\,\mathrm{d}s. \tag{8.31}$$

The function $\bar{x}$, by assumption, satisfies the two-point condition (8.9),

$$A\bar{x}(0) + \bar{x}(T) = d - B\lambda,$$

and the initial condition $\bar{x}(0) = z$, whence

$$\bar{x}(T) = d - B\lambda - Az.$$

Similarly, on can verify that

$$\bar{\bar{x}}(T) = d - B\lambda - Az.$$

Therefore, (8.30) and (8.31) yield

$$\bar{\mu} = \frac{1}{T}\left(d - B\lambda - Az - z - \int_0^T f\big(s, \bar{x}(s)\big)\,\mathrm{d}s\right) \tag{8.32}$$

and

$$\bar{\bar{\mu}} = \frac{1}{T}\left(d - B\lambda - Az - z - \int_0^T f\big(s, \bar{\bar{x}}(s)\big)\,\mathrm{d}s\right). \tag{8.33}$$

Substituting (8.32) and (8.33) into (8.28) and (8.29), respectively, we obtain that

$$\begin{aligned} \bar{x}(t) = z &+ \int_0^t f\big(s, \bar{x}(s)\big)\,\mathrm{d}s \\ &+ \frac{t}{T}\left[d - B\lambda - Az - z - \int_0^T f\big(s, \bar{x}(s)\big)\,\mathrm{d}s\right] \end{aligned} \tag{8.34}$$

and

$$\begin{aligned} \bar{\bar{x}}(t) = z &+ \int_0^t f\big(s, \bar{x}(s)\big)\,\mathrm{d}s \\ &+ \frac{t}{T}\left[d - B\lambda - Az - z - \int_0^T f(s, \bar{\bar{x}}(s))\,\mathrm{d}s\right] \end{aligned} \tag{8.35}$$

for any $t \in [0, T]$. We recall that here $z \in \Gamma$ and $\lambda \in \Lambda$. Therefore, similarly to the proof of Theorem 8.3, by using the form of Eqs. (8.34), (8.35) and definition (8.11) of the set Γ, we can show that all the values of the functions $\bar{\bar{x}}$ and $\bar{x}$ are contained in D:

$$\bar{x}\big([0, T]\big) \cup \bar{\bar{x}}\big([0, T]\big) \subset D. \tag{8.36}$$

It is obvious from (8.34) and (8.35) that

$$\begin{aligned} \bar{\bar{x}}(t) - \bar{x}(t) = &\int_0^t \big[f\big(s, \bar{\bar{x}}(s)\big) - f\big(s, \bar{x}(s)\big)\big]\,\mathrm{d}s \\ &- \frac{t}{T}\int_0^T \big[f\big(s, \bar{\bar{x}}(s)\big) - f\big(s, \bar{x}(s)\big)\big]\,\mathrm{d}s, \quad t \in [0, T], \end{aligned}$$

and, hence, by virtue of relation (8.36) and the Lipschitz condition (3.5), the function

$$r(t) := \big|\bar{\bar{x}}(t) - \bar{x}(t)\big|, \quad t \in [0, T],$$

satisfies the integral inequality

$$\begin{aligned} r(t) &\leqslant K\left[\int_0^t r(s)\,\mathrm{d}s + \frac{t}{T}\int_0^T r(s)\,\mathrm{d}s\right] \\ &\leqslant K\alpha_{1,T}(t) \max_{s\in[a,b]} r(s), \quad t \in [0, T], \end{aligned} \tag{8.37}$$

where the function $\alpha_{1,T}$ is given by formula (3.34). Using (8.37) sequentially, we arrive at the inequality

$$r(t) \leqslant K^m \alpha_{m,T}(t) \max_{s\in[a,b]} r(s), \quad t \in [0,T], \tag{8.38}$$

where the natural m is arbitrary and $\alpha_{m,T}$ is defined by relation (3.35). According to Lemma 2.4 from [70], functions (3.35) for all $t \in [0,T]$ and $k = 1, 2, \ldots$ admit estimate (3.36). Consequently, it follows from (8.38) that, for any natural m,

$$r(t) \leqslant \frac{10}{9} K\alpha_{1,T}(t)\left(\frac{3T}{10}K\right)^{m-1} \max_{s\in[a,b]} r(s), \quad t \in [0,T]. \tag{8.39}$$

Letting in (8.39) m tend to $+\infty$ and taking condition (6.14) into account, we conclude that $r \equiv 0$ on $[0,T]$, i.e., the functions $\bar{x}$ and $\bar{\bar{x}}$ coincide with one another, and hence $\bar{\mu} = \bar{\bar{\mu}}$. The contradiction obtained proves that $\mu = T^{-1}\Delta(z,\lambda)$ is the unique value of the parameter μ in Eq. (8.24), for which the solution of the initial value problem (8.24), (8.23) satisfies the two-point condition (8.9). □

REMARK 8.8. It follows from Lemma 7.5 that for an arbitrarily small positive ε there always exists a number $k_\varepsilon \in \mathbb{N}$ such that functions (3.35), starting with the k_εth one, admit the estimate

$$\alpha_{k,T}(t) \leqslant \left(\frac{T}{q} + \varepsilon\right)^{k-k_\varepsilon} \alpha_{k_\varepsilon,T}(t), \quad t \in [0,T],\ k \geqslant k_\varepsilon, \tag{8.40}$$

where $q \approx 3.416131$. Using (8.40) instead of estimate (3.36) and modifying appropriately the proofs of Theorems 8.3 and 8.6, one ca show that inequality (6.14) can be replaced by the weaker condition $r(K) < qT^{-1}$. All the related statements are preserved in this case at the expense of certain technical modifications of the argument (e.g., the form of the function h in estimate (8.20)).

Let us make clear how the function (8.16) defined in Theorems 8.3 and 8.6 is related to the set of solutions of the two-point problem (2.1), (8.9) containing a free parameter $\lambda \in \Lambda$.

PROPOSITION 8.9. *Under conditions of Theorem* 8.3, *the function* $x^*(\cdot, z, \lambda)$ *given by formula* (8.16) *for* $(z,\lambda) \in \Gamma \times \Lambda$, *is a solution of the two-point problem* (2.1), (8.9) *with the parameter* λ *if and only if* z *and* λ *satisfy the relation*

$$\int_0^T f\big(s, x^*(s,z,\lambda)\big)\,\mathrm{d}s = d - B\lambda - Az - z. \tag{8.41}$$

Function (8.16) *is a solution of the original three-point problem* (2.1), (8.7) *if and only if the pair* (z,λ) *satisfies condition* (8.41), *and, moreover,*

$$x^*(\xi, z, \lambda) = \lambda. \tag{8.42}$$

PROOF. It follows from Theorem 8.3 that for all $(z, \lambda) \in \Gamma \times \Lambda$ the function $x^*(\cdot, z, \lambda)$ is a solution of the two-point problem (8.18), (8.9). Equation (8.18) coincides with Eq. (2.1) if and only if z and λ satisfy condition $\Delta(z, \lambda) = 0$, i.e., equality (8.41) holds. The second assertion follows from Remark 8.1. □

8.4. *Practical realisation*

When putting the suggested scheme to practise, it is natural to fix a certain iteration number, m, in (8.12) and regard $x_m(\cdot, z, \lambda)$ as an approximation to the unknown function $x^*(\cdot, z, \lambda)$, the existence of which is stated in Theorem 8.3. In this case, instead of Eqs. (8.41), (8.42), the "approximate determining equations"

$$\int_0^T f\bigl(s, x_m(s, z, \lambda)\bigr)\,\mathrm{d}s = d - B\lambda - Az - z \tag{8.43}$$

and

$$\begin{aligned} z + \int_0^t f\bigl(s, x_m(s, z, \lambda)\bigr)\,\mathrm{d}s - tT^{-1}\int_0^T f\bigl(s, x_m(s, z, \lambda)\bigr)\,\mathrm{d}s \\ + tT^{-1}[d - B\lambda - Az - z] = \lambda. \end{aligned} \tag{8.44}$$

arise, from which we can find suitable values of the pair of parameters $(z, \lambda) \in \Gamma \times \Lambda$. If the system of $2n$ Eqs. (8.43), (8.44) has an isolated solution $(\bar{z}, \bar{\lambda}) \in \Gamma \times \Lambda$, then, by using topological and functional-analytic methods (see, e.g., Theorem 3.1 in [70] and Theorem 19.2 in [37]), under the appropriate additional assumptions, one can prove that system (8.41), (8.42) is also solvable and, thus establishing the existence of a solution of the original three-point problem. The function

$$\bar{x}_m(t) := x_m(\cdot, \bar{z}, \bar{\lambda}), \quad t \in [0, T], \tag{8.45}$$

can then be regarded as an approximation to a solution of problem (2.1), (8.7).

8.5. *Example of a two-dimensional three-point problem*

Let us consider the three-point boundary value problem

$$x_1'(t) = x_2(t), \tag{8.46a}$$

$$x_2'(t) = \frac{1}{8}tx_2 - \frac{1}{2}{x_2}^2 - \frac{1}{2}x_1 + \frac{9}{32} + \frac{1}{16}t^2, \quad t \in [0, 1], \tag{8.46b}$$

$$x_2(0) + x_1\left(\frac{1}{2}\right) + x_1(1) = \frac{9}{32}, \tag{8.46c}$$

$$x_1(0) + x_2(1) = \frac{5}{16}. \tag{8.46d}$$

Conditions (8.46c), (8.46d), clearly, can be written in form (8.7) with $T = 1$ and

$$A := \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad B := \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad d := \begin{bmatrix} \frac{9}{32} \\ \frac{5}{16} \end{bmatrix}, \quad \xi := \frac{1}{2}. \tag{8.47}$$

Let us restrict our consideration by those solutions of system (8.46a), (8.46b), all the values of which are contained in the set

$$D := \left\{ (x_1, x_2) \colon \ |x_1| \leqslant 1, |x_2| \leqslant \frac{3}{4} \right\}. \tag{8.48}$$

It is not difficult to verify that, for all $t \in [0, 1]$ and $\{u, v\} \subset D$, the function $f : [0, 1] \times D \to \mathbb{R}^2$ given by the formula

$$f(t, x_1, x_2) := \left[\ x_2 \tfrac{1}{8} t x_2 - \tfrac{1}{2} {x_2}^2 - \tfrac{1}{2} x_1 + \tfrac{9}{32} + \tfrac{t^2}{16} \ \right], \quad (t, x_1, x_2) \in [0, 1] \times D,$$

satisfies the Lipschitz condition (3.5) with the matrix

$$K := \begin{bmatrix} 0 & 1 \\ \frac{1}{2} & \frac{7}{8} \end{bmatrix}. \tag{8.49}$$

The greatest eigenvalue of matrix (8.49) is equal to $(7 + \sqrt{177})/16 \approx 1.27$, which is less than $\frac{10}{3}$, and, hence, inequality (6.14) holds.

Let us seek for the solutions of the three-point problem (8.46) among the solutions of system (8.46a), (8.46b) satisfying the parametrised two-point conditions

$$x_2(0) + x_1(1) = \frac{9}{32} - \lambda_1, \tag{8.50}$$

$$x_1(0) + x_2(1) = \frac{5}{16}. \tag{8.51}$$

Conditions (8.50), (8.51), obviously, coincide with (8.9) for A, B, and d given by (8.47). For the domain where the two-dimensional vector of parameters $\lambda = (\lambda_1, \lambda_2)$ varies, we take, e.g., the rectangle

$$\Lambda := \left\{ (\lambda_1, \lambda_2) \colon \ |\lambda_1| \leqslant \frac{1}{4}, |\lambda_2| \leqslant \frac{1}{2} \right\} \tag{8.52}$$

contained in set (8.48). A solution (x_1, x_2) of problem (8.46a), (8.46b), (8.50), (8.51) is a solution of the original three-point problem (8.46) if and only if the additional conditions $x_1(\frac{1}{2}) = \lambda_1$ and $x_2(\frac{1}{2}) = \lambda_2$ are satisfied.

Let us use the approach based on Theorem 8.3, for which purpose verify the fulfilment of its assumptions. It is easy to see that the value $\delta_D(f)$ in the case considered is given by the equality

$$\delta_D(f) = \frac{1}{2}\begin{bmatrix} 3 \\ \frac{355}{128} \end{bmatrix}. \tag{8.53}$$

Furthermore, it is clear from (8.48), (8.52), (8.47), and (8.53) that, for our problem, the components of the function $\binom{\beta_1}{\beta_2} : D \times \Lambda \to \mathbb{R}^2$ defined by equality (8.10) have the form

$$\beta_1(z_1, z_2, \lambda_1, \lambda_2) = \frac{3}{8} + \left|\frac{9}{32} - \lambda_1 - z_1 - z_2\right|,$$

$$\beta_2(z_1, z_2, \lambda_1, \lambda_2) = \frac{355}{1024} + \left|\frac{5}{15} - z_1 - z_2\right|.$$

Therefore, according to the definition (8.11) of the set Γ, a point (z_1, z_2) from D belongs to Γ if and only if

$$\left|\frac{9}{32} - \lambda_1 - z_1 - z_2\right| \leqslant \frac{5}{8}, \tag{8.54}$$

$$\left|\frac{5}{15} - z_1 - z_2\right| \leqslant \frac{413}{1024} \tag{8.55}$$

for all $\lambda_1 \in [-\frac{1}{4}, \frac{1}{4}]$. The set Γ of such pairs $(z_1, z_2) \in D$ is obviously non-empty. Thus, all the conditions of Theorem 8.3 are satisfied in this case and, therefore, for any $(z, \lambda) \in \Gamma \times \Lambda$, on [0, 1], the function (8.16) discussed in Theorem 8.6 and Proposition 8.9 is well-defined.

Let us construct approximate solutions of problem (8.46) by using the approach indicated in Section 8.4. For this purpose, we compute analytically several members of the recurrence function sequence (8.12) with the help of Maple [29]. Let us set the zeroth iteration to be equal identically to z, $z \in \Gamma$. Then for $m = 1$ relation (8.12) yields

$$x_{11}(t, z_1, z_2, \lambda_1, \lambda_2) = z_1 + \frac{9}{32}t - t\lambda_1 - z_1 t - z_2 t, \tag{8.56}$$

$$x_{12}(t, z_1, z_2, \lambda_1, \lambda_2) = z_2 + \frac{7}{24}t + \frac{1}{48}t^3 + \frac{1}{16}z_2 t^2 - \frac{17}{16}z_2 t - z_1 t \tag{8.57}$$

for any $t \in [0, 1]$, $(z_1, z_2) \in \Gamma$, and λ_1, λ_2 satisfying the inequalities

$$|\lambda_1| \leqslant \frac{1}{4}, \qquad |\lambda_2| \leqslant \frac{1}{2}.$$

Here and below, the symbols x_{k1} and x_{k2} designate, respectively, the first and the second components of the vector x_k.

For $m = 1$, the system approximate determining equations (8.43), (8.44) corresponding to problem (8.46) consists of the equations

$$\frac{25}{192} - \frac{143}{96}z_2 - \frac{1}{2}z_1 - \lambda_1 = 0, \tag{8.58}$$

$$\frac{40391}{483840} - \frac{28157}{23040}z_2 - \frac{583}{720}z_1 + \frac{827}{5120}z_2^2 - \frac{31}{192}z_2z_1 + \frac{1}{6}z_1^2 - \frac{1}{4}\lambda_1 = 0, \tag{8.59}$$

$$\frac{5}{8}z_1 + \frac{313}{3072} - \frac{3}{8}z_2 - \frac{3}{2}\lambda_1 = 0, \tag{8.60}$$

and

$$\begin{aligned}&\frac{129067}{294912}z_2 + \frac{98569}{589824} - \frac{899}{1536}z_1 - \frac{63}{1024}z_2^2\\ &\quad + \frac{1}{1024}z_2z_1 + \frac{1}{16}z_1^2 - \frac{1}{16}\lambda_1 - \lambda_2 = 0.\end{aligned} \tag{8.61}$$

REMARK 8.10. The rank of the matrix B corresponding to the two-point conditions (8.46c), (8.46d) rewritten in form (8.7) is equal to 1 (the conditions do not contain explicitly $x_2(\frac{1}{2})$). Therefore, in view of Remark 8.2, the determining equations — both those given above and the other ones — need not be solved with respect to the parameter λ_2 because its value does not play any role in for problem considered. In this example we, however, write down all the equations completely in order to illustrate the approach.

Solving the system of Eqs. (8.58)–(8.60), (8.61) numerically, we obtain

$$z_1 \approx 0.06775109879, \qquad z_2 \approx 0.006168107627, \tag{8.62}$$

$$\lambda_1 \approx 0.08714487359, \qquad \lambda_2 \approx 0.125. \tag{8.63}$$

Substituting (8.62), (8.63) into (8.56) and (8.57), we find a function of form (8.45) – the "first approximation" to a solution of the three-point problem (8.46) corresponding to the values (8.62), (8.63) of the parameters z_1, z_2 and λ_1, λ_2 computed above:

$$\begin{aligned}\bar{x}_{11}(t) &= 0.06775109879 + 0.1201859200t,\\ \bar{x}_{12}(t) &= 0.006168107627 + 0.2173619535t\\ &\qquad + \frac{t^3}{48} + 0.0003855067267t^2.\end{aligned} \tag{8.64}$$

Note that the given three-point problem (8.46) has the solution

$$x_1(t) = \frac{t^2}{8} + \frac{1}{16}, \quad x_2(t) = \frac{t}{4}, \quad t \in [0, 1], \tag{8.65}$$

passing through the point $(\frac{1}{16}, 0)$ of the set Γ at the moment of time 0.

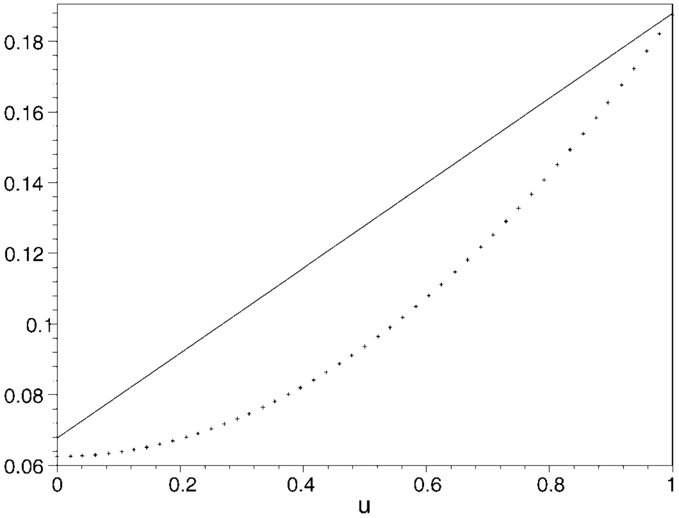

Fig. 9. The first component of the exact solution (8.65) and its “first approximation” (8.64).

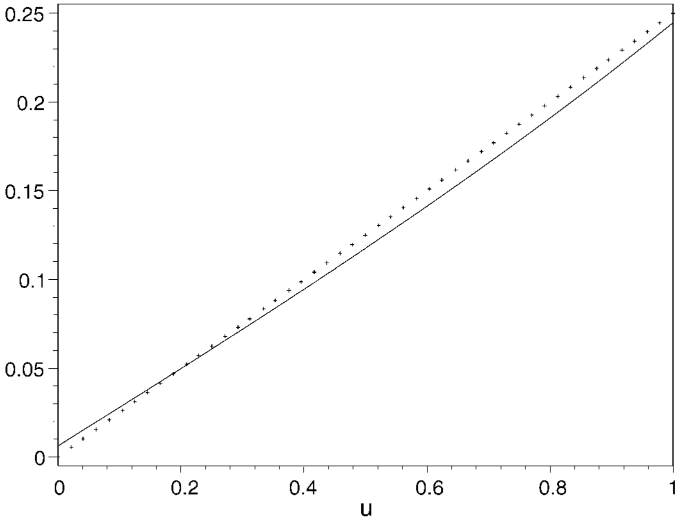

Fig. 10. The second component of the exact solution (8.65) and its “first approximation” (8.64).

Figs. 9 and 10 show the graphs of the first and the second components of the exact solution (8.65) of problem (8.46) (dotted line) and its “first approximation” (8.64) (solid line). The components of the deviation of the “first approximation” (8.64) from solution (8.65), i.e., the functions $x_1 - \bar{x}_{11}$ and $x_2 - \bar{x}_{12}$, are shown, respectively, on Figs. 13 and 14.

In a similar way, by using formulae (8.56) and (8.57) that have been derived above for the first iteration, one can find the second iteration $x_2(\cdot, z_1, z_2, \lambda_1, \lambda_2)$ (i.e., $m = 2$ in formula

(8.12)), the components of which have the form

$$\begin{aligned} x_{21}(t, z_1, z_2, \lambda_1, \lambda_2) = z_1 &+ \frac{t^4}{192} + \frac{t^3}{48} z_2 + \frac{7t^2}{48} - \frac{17t^2}{32} z_2 - \frac{t^2}{2} z_1 \\ &- \frac{47t}{96} z_2 + \frac{25t}{192} - \frac{t}{2} z_1 - t\lambda_1, \quad t \in [0, 1], \end{aligned} \tag{8.66}$$

and

$$\begin{aligned} x_{22}(t, z_1, z_2, \lambda_1, \lambda_2) = z_2 &+ \frac{176471}{483840} t - \frac{28157}{23040} z_2 t + \frac{17t^3}{288} z_2 + \frac{t^2}{6} z_2 + \frac{t^2}{4} z_1 \\ &- \frac{t^6 z_2}{4608} - \frac{943t}{720} z_1 - \frac{1733}{5120} z_2^2 t + \frac{17t^5 z_2}{3840} + \frac{t^5 z_1}{240} - \frac{t^5 z_2^2}{2560} \\ &- \frac{t^4 z_2}{128} + \frac{17t^4 z_2^2}{1024} - \frac{107t^3 z_2^2}{512} + \frac{t^3 z_1}{18} - \frac{t^3 z_1^2}{6} + \frac{65t^3}{3456} \\ &- \frac{9t^2}{128} - \frac{t^5}{1440} - \frac{t^7}{32256} + \frac{t^2}{2} z_2 z_1 + \frac{17t^2}{32} z_2^2 + \frac{t^2}{4} \lambda_1 \\ &+ \frac{t}{6} z_1^2 - \frac{t}{4} \lambda_1 + \frac{t^4}{64} z_2 z_1 - \frac{31}{192} t z_2 z_1 \\ &- \frac{17}{48} t^3 z_2 z_1, \quad t \in [0, 1], \end{aligned} \tag{8.67}$$

and construct the corresponding system of Eqs. (8.43), (8.44) for determining the values of z_1, z_2, λ_1, and λ_2. The system mentioned, as the computation shows, has the approximate solution

$$z_1 \approx 0.06242777432, \qquad z_2 \approx 0.0001215436768, \tag{8.68}$$

$$\lambda_2 \approx 0.125, \qquad \lambda_1 \approx 0.09364329365. \tag{8.69}$$

Substituting (8.68), (8.69) in (8.66) and (8.67), we obtain the "second approximation," the components of which are given by the formulae

$$\begin{aligned} \bar{x}_{21}(t) = 0.06242777432 &+ \frac{t^4}{192} + 0.2532159933 \times 10^{-5} t^3 \\ &+ 0.1145548760 t^2 + 0.0052916467 t, \quad t \in [0, 1], \end{aligned} \tag{8.70}$$

and

$$\begin{aligned} \bar{x}_{22}(t) = &-0.2637666597 \times 10^{-7} t^6 + 0.2600559795 t + 0.0001215436768 \\ &- 0.8307568908 \times 10^{-6} t^4 + 0.02163102627 t^3 - 0.03127067403 t^2 \\ &- 0.0004337906399 t^5 - \frac{t^7}{32256}, \quad t \in [0, 1], \end{aligned} \tag{8.71}$$

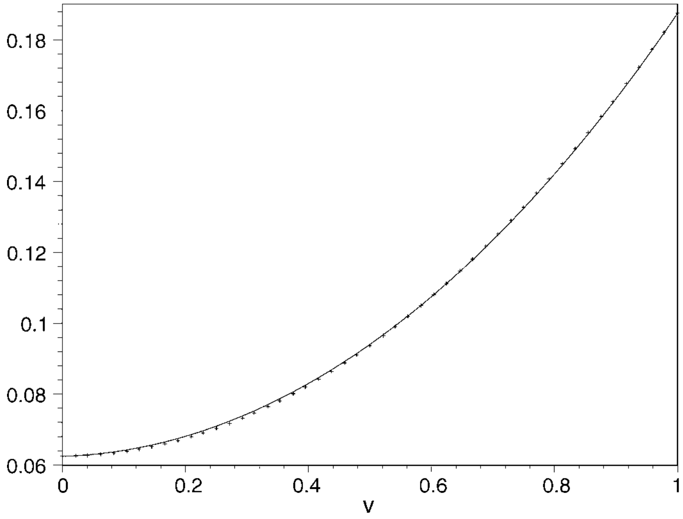

Fig. 11. The first component of solution (8.65) and its “second approximation” (8.70).

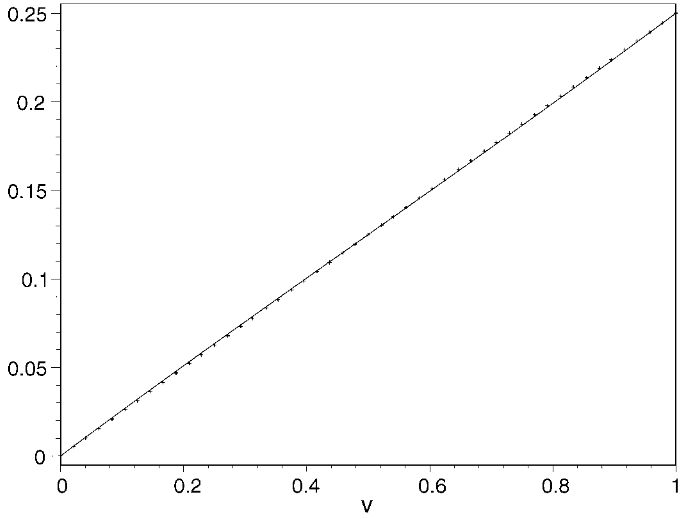

Fig. 12. The second component of solution (8.65) and its “second approximation” (8.71).

respectively.

Figure 11 shows the graph of the first component of the solution (8.65) of problem (8.46) (dotted line) and its “second approximation” (8.70) (solid line). On Fig. 12, the graphs of the second component of solution (8.65) (dotted line) and its “second approximation” (8.71) (solid line) are presented. The curves almost coincide with one another. The error of the second approximation is drawn on Figs. 15 and 16.

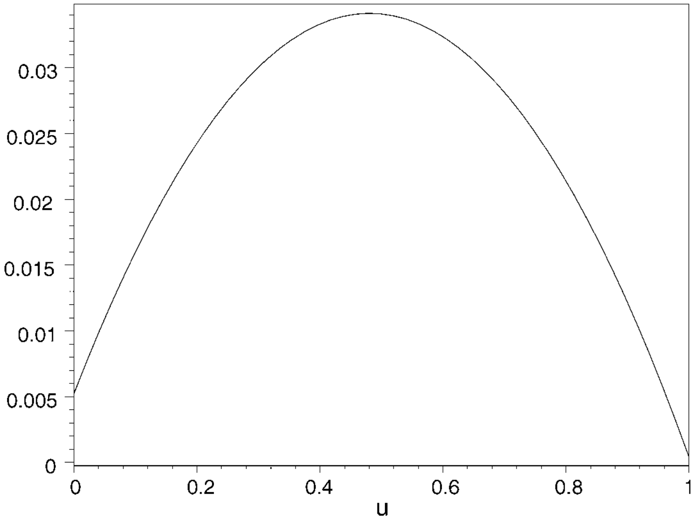

Fig. 13. Error of the first component of the “first approximation” (8.64) with respect to solution (8.65).

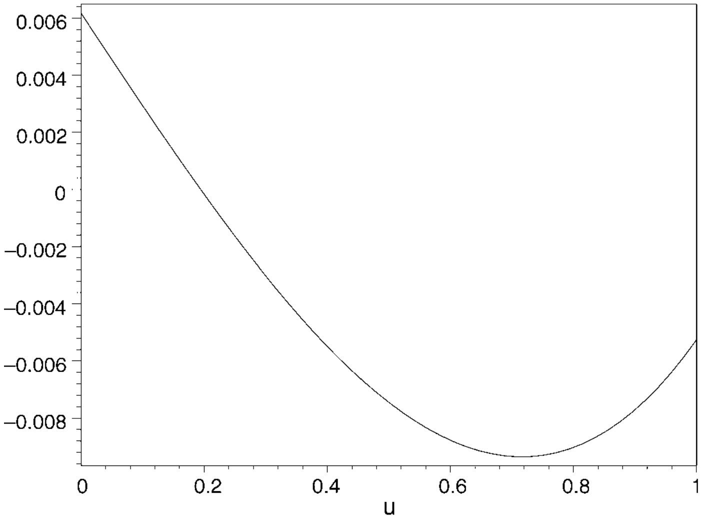

Fig. 14. Error of the second component of the “first approximation” (8.64) with respect to solution (8.65).

The computation shows that the third approximation constructed according to the scheme indicated above gives the absolute error which does not exceed 0.00035 for the first component and 0.0001 for the second one.

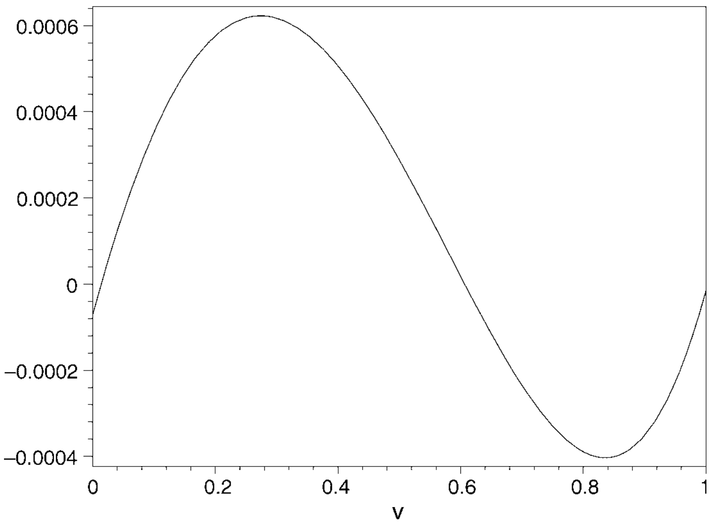

Fig. 15. Error of the “second approximation” (8.70) to the first component of solution (8.65).

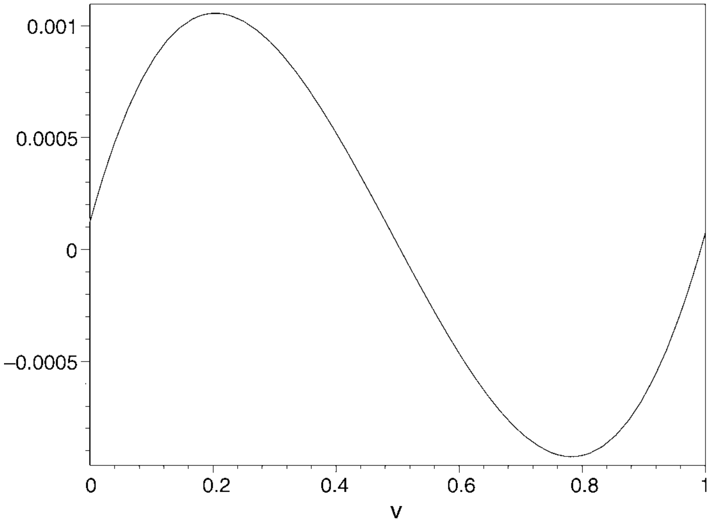

Fig. 16. Error of the “second approximation” (8.71) to the second component of solution (8.65).

9. Historical remarks

The basic concepts of the successive approximation method considered here had been first introduced by Samoilenko [82,83] in connection with the study of the periodic boundary value problem (2.1), (2.2) and was referred to as the “numerical-analytic method” and “periodic successive approximations method”. Some its aspects, as was noticed afterwards, have common points with other methods oriented to the investigation of periodic solutions of non-autonomous systems of differential equations.

The survey papers [74,76,77,75,78–80] analyse the history of the method and many interesting works inspired by it. Among the other works concerning the successive approximation method for boundary value problems, we mention the paper [74] and the Appendix of the book [70] which analyse the relation of the method to the Lyapunov–Schmidt equation [48], with the Cesari–Hale method for weakly non-linear differential equations [12], with the Cesari scheme for essentially non-linear systems of ordinary differential equations [11], and with the integral operator M_J introduced by Mawhin [81, pp. 98–107] as a mapping in C_T whose fixed points coincide with the solutions of a T-periodic boundary value problem for system (2.1). For example, the result on the existence of T-periodic solutions established in [81] (see Theorem 2.3, Corollary 4.4, and Remark 4.5 in [81]) can also be obtained with the help of the successive approximations method discussed here. In [70, Appendix] by Rontó, Samoilenko, and Trofimchuk, such a result is presented as Theorem 10, in the formulation borrowed from [72].

Note that a result close to the above-mentioned Theorem 10 from [70] had been first proved by Mawhin in 1969 for a locally Lipschitzian equation by using the Cesari method [81]. The statement indicated can be regarded as a consequence of the coincidence degree theory (see [81, p. 225] and [24]).

The improvement of the applicability conditions of the successive approximations method under consideration and estimates appearing in Theorems 3.17, 3.22, 3.23, 3.28, 3.36, 4.2, 6.1, and 8.3, Lemma 3.26, and inequality (4.25), involving the matrix Q of form (3.9), is closely related to the refinement of the constant q. Clearly, the more q is, the wider the domain of application of the iteration scheme will be. The following list describes, in the chronological order, the constants used in various estimates related to the successive approximation method:

1965 Samoilenko [82,83]; $q = 3.1$.

1976 Samoilenko and Ronto [88]; $q = \pi$.

1982 Samoilenko and Laptinskii [86]; $q = 3.416\ldots$. The proof has a gap which can be eliminated by using the Krein–Rutman theorem [38].

1985 Evhuta and Zabreiko [15,16]; $q = 3.416\ldots$.

1990 Trofimchuk [104]; $q = 3.416\ldots$. It is also proved that $q \leqslant 2\pi$. The estimates obtained are rather complicated and difficult to apply due to the need to compute the values of some integral operators.

1992 Kwapisz [42]; $q = \sqrt{10} = 3.1622\ldots$.

1996 Rontó and Mészáros [69]; $q = \frac{10}{3}$.

1996 Rontó, Rontó, Samoilenko, and Trofimchuk [64]; $q = 3.416\ldots$. Convenient techniques for the computation of constants in estimates are suggested.

2001 Perov, Dikareva, Oleinikova, and Portnov [57]; $q = \pi$. Three methods of proof are presented. In the first one, certain inaccuracies in some auxiliary statements used in [82,83,88] are corrected, whereas the second one uses the Steklov inequality [55, 56,14]. The third approach suggested allowed the authors to improve the a priori estimates by determining the maximal eigenvalues of certain integral operators.

2003 Samoilenko [85]; $q = 3.416\ldots$. The value of the constant was determined as the convergence radius of the Poisson–Abel series (5.64).

Using the idea of the successive approximations method first introduced for the study of the periodic solutions, many authors developed its versions adopted to the investigation of other kinds of boundary value problems for various types of ordinary differential, integro-differential, and more general functional differential equations and their systems. Many such papers are discussed in [74,76,77,75,78–80] and in the Appendix of [70].

Section A3.1 in [70, Appendix] analyses, in particular, the analogues of the successive approximations (3.29) constructed directly for the scalar second-order non-linear Lipschitzian differential equation

$$x''(t) + \omega^2 x(t) = f\big(t, x(t), x'(t)\big), \quad t \in [0, T], \tag{9.1}$$

without reduction of (9.1) to an equivalent system of first order equations. The convergence corresponding conditions turned out to be significantly worse compared to their counterparts for first order systems [70, p. 339]. The scheme of the successive approximations was adjusted for finding the periodic solutions of second order equations by Strizhak [102] and Samoilenko and Ronto [89]. Some modifications of the method were applied by Mitropolskii, Khoma, and Gromyak [50] in order to prove existence theorems to the T-periodic problem

$$x(0) = x(T), \qquad x'(0) = x'(T), \tag{9.2}$$

for Eq. (9.1) with $\omega \neq 0$, both in the non-resonance and resonance cases. The conditions of convergence of the scheme from [50] in the non-resonance case are rather restrictive.

Existence and uniqueness results for the non-resonance T-periodic boundary value problem (9.1), (9.2) were established by Chornyĭ [13]. Another scheme, which is also applicable in the cases where the Lipschitz constants for f in (9.1) are large, was suggested by Perestyuk and Ronto [53]. Problem (9.2) for some types of second order differential equations was studied by Shlapak [97,98], Sobkovich [99], Ronto and Martynyuk [73], and many others (see, e.g., [70, Appendix] for references).

Modified versions of the successive approximation scheme of form (3.29) for the study of T-periodic solutions of the delay differential system

$$x'(t) = f\big(t, x(t), x(t-\delta)\big), \quad t \in [0, T], \tag{9.3}$$

was first introduced by Martynyuk and Samoilenko [47], Mitropolʹskiĭ, Samoilenko, and Martynyuk [51] and the role of the delay, δ, pointed out.

Versions of the successive approximations obtained from (3.29) by a certain change of variables were used by Augustynowicz and Kwapisz [7], Kwapisz [42,44,43] for the investigation of solutions of the neutral type functional differential equation

$$x'(t) = f\big(t, x\big(\alpha(t)\big), x'\big(\beta(t)\big)\big), \quad t \in [0, T], \tag{9.4}$$

subjected to the two-point boundary conditions of the form

$$Ax(0) + Bx(T) = d,$$

where $\{A, B\} \subset \mathrm{GL}_n(\mathbb{R})$, $d \in \mathbb{R}^n$, and α, β are functions mapping the interval $[0, T]$ into itself (see Section A3.2.2 in [70, p. 369]).

Techniques based upon successive approximations of the kind indicated were used by Baĭnov and Sarafova [8] for integro-differential equations and Sarafova [95,96,9] Ronto [62] for differential equations with “maxima.” Zavalykut [107], Zavalykut and Nurzhanov [106] extended the techniques discussed to the more general differential operator equations of the form

$$x'(t) = (Ax)(t), \quad t \in (-\infty, \infty),$$

where A is a continuous mapping defined on the space C_T (see also [70, Section A3.3]).

Successive approximation techniques were applied for impulsive systems by Samoilenko [84], Samoilenko and Perestyuk [87], Kurbanbaev [40], Perestyuk and Shovkoplyas [54].

In [78], the application of the successive approximations method to difference equations is analysed. The paper [79] deals with its application to various non-linear boundary value problems (see also [60,39]). The paper [80] gives a survey of works devoted to successive approximation techniques for differential equations in Banach spaces, certain types of implicit differential equations, and to boundary value problems containing a control parameter (see also Akhmet and Zafer [4], Jankowski [34,32,33,31], Ronto, Ronto, and Shchobak [65]).

10. Exercises

Here, we suggest several exercises related to the techniques discussed.

EXERCISE 10.1. Study in which sense the family of sets $\{\Omega_{m,N}\}$ tends to the set Ω^* in Remark 3.37.

EXERCISE 10.2. For Eq. (4.96) in Example 4.9, by using the scheme (4.96), construct the functions $y_1(\theta, c, \mu)$ and $y_2(\theta, c, \mu)$. Write down the corresponding determining equations (4.45) and construct the 1st and the 2nd approximate periodic solutions (4.56) of Eq. (4.96). Find the corresponding values of c and T, compare them to ε and 2π (cf. (4.111)).

EXERCISE 10.3. Investigate the properties of the sequence $\alpha_{m,T}$, $m \geqslant 0$, given by formula (3.35). Prove the equality

$$\begin{aligned}\lim_{m\to\infty} \max_{t\in[0,T]} \frac{\alpha_{m,T}(t)}{\alpha_{m+1,T}(t)} &= \lim_{m\to\infty} \frac{\max_{t\in[0,T]} \alpha_{m,T}(t)}{\max_{t\in[0,T]} \alpha_{m+1,T}(t)} \\ &= \lim_{m\to\infty} \frac{\alpha_{m,T}(T/2)}{\alpha_{m+1,T}(T/2)} = \frac{1}{Tr(\mathcal{A})},\end{aligned}$$

where $\mathcal{A}$ is the linear operator in the space $C([0,1])$ given by the formula

$$(\mathcal{A}x)(s) := (1-s)\int_0^s x(\xi)\,\mathrm{d}\xi + s\int_s^1 x(\xi)\,\mathrm{d}\xi, \quad s \in [0,1]. \tag{10.1}$$

EXERCISE 10.4. Compute approximately the spectral radius $r(\mathcal{A})$ of operator (10.1). Hint: $r(\mathcal{A}) \approx 0.29$, see [60].

EXERCISE 10.5. Show how is it possible to relax condition (3.7). Hint: use Problems 10.3 and 10.4 and see [60] to show that the constant $3/10$ in (3.7) can be replaced by $r(\mathcal{A})$.

EXERCISE 10.6. For the periodic boundary value problem for the differential equation of the form

$$x'(t) = f\big(t, x, x'(t)\big), \quad t \in [0,T],$$

construct a suitable successive approximation method instead of that based upon the iteration scheme (3.29). Hint: see Section 3.10 in [80].

Abstract

The article is devoted to the local theory of analytic differential equations. We describe classification of meromorphic systems $\dot{x} = A(t)x$ near regular and irregular singular point. We present a local theory of non-linear holomorphic equations $\dot{x} = V(x)$, with the proof of

the resolution theorem and its application to the center–focus problem, with Ecalle–Voronin–Martinet–Ramis moduli and with Briuno–Yoccoz classification of non-resonant saddles. Finally, we present formal classification of nilpotent singularities and prove analyticity of the Takens prenormal form.

MSC: primary 05C38, 15A15; secondary 05A15, 15A18

1. Introduction

The origins of the theory of Ordinary Differential Equations lie in the classical mechanics. The second Newton's principle of dynamics states that the further configurations of a mechanical system are determined by the initial positions and velocities via a second order differential equation. Therefore the theory is essentially real, because the time is real. But in the conservative mechanical systems the direction of time is not that important, the corresponding Newton's equations are time–reversible. Even in the non-conservative case the knowledge of the initial positions and velocities at $t = 0$ allows to reconstruct the history of the system.

Therefore, in the philosophical sense, the theory of Ordinary Differential Equations resembles other mathematical theories: the Riemannian geometry, the real algebraic geometry, the Morse theory of functions, etc. In all these theories the extension to the complex domain turned out very effective. For example, the Morse theory describes the change of topology of level surfaces of a function during passage through a critical value; but in the case of holomorphic function one can pass along a loop around the critical value and the resulting change in the topology of level surface is described by the Picard–Lefschetz formula.

It is not surprising that also the theory of Ordinary Differential Equations has its holomorphic analogue. It is the analytic theory of Ordinary Differential Equations, which does not concentrate on solutions in the form of power series, but rather treats the time as complex and represents solutions as embeddings of Riemann surfaces into a complex phase space. This approach was used already in the works of K. Gauss (on the hypergeometric equations) and of B. Riemann (in the so-called Riemann–Hilbert problem).

The aim of this article is to present the local theory of analytic Ordinary Differential Equations. It is an analogue of the singularity theory of holomorphic functions (generalization of the Morse Lemma). It turns out that the classification of singularities of differential equations is more complicated than in the geometrical case. It is related with the Stokes phenomenon for linear differential systems, when some asymptotic expansions of solutions are valid only in some sectors (in the complex time plane) and the 'differences' between the expansions in adjacent sectors constitute functional moduli of the singularity. There exists also a non-linear version of the Stokes phenomenon in the orbital classification of holomorphic planar vector fields near elementary singular point. In the case of non-elementary singularity the situation is even more complicated, e.g. in the nilpotent case only the formal orbital classification is known.

2. Linear differential equations

The subject in this chapter are the non-autonomous linear differential systems

$$\dot{z} = A(t)z, \quad z \in \mathbb{C}^n, \tag{2.1}$$

and the linear higher order differential equations

$$x^{(n)} + a_1(t)x^{(n-1)} + \cdots + a_n(t)x = 0, \quad x \in \mathbb{C}. \tag{2.2}$$

In the above two equations the ‘time’ t usually takes value in the complex plane $\mathbb{C}$. Often we will consider Eqs. (2.1) and (2.2) locally, then $t \in (\mathbb{C}, 0)$.

The entries of the matrix $A(t)$ and the coefficients $a_i(t)$ are meromorphic functions.

The equations of this type are met very often. For example, the *Gauss hypergeometric equation*

$$t(t-1)\ddot{x} + \big[(\alpha+\beta+1)t - \gamma\big]\dot{x} + \alpha\beta x = 0 \tag{2.3}$$

belongs to this class. Probably it is the most important linear differential equation. Most of the differential equations appearing in the theory of special functions, e.g. the Bessel equation, the Weber equation, the Legendre equation, the Hermite equation, the Jacobi equation, are obtained from the hypergeometric equation by application of some limit process.

Algebraic functions are also solutions of such differential equations. It follows from the Riemann theorem about multivalued holomorphic functions with regular singularities (see [89]). For example, the function $x(t) = \sqrt{t} + \sqrt[3]{t-1}$ satisfies the equation

$$(t-3)\frac{\mathrm{d}}{\mathrm{d}t}\big(6t(t-1)\dot{x}\big) = 3(3t-1)\big[3(t-1)\dot{x} - x\big] + 2(4t-3)[2t\dot{x} - x].$$

DEFINITION 2.1. A point t_* at which the matrix $A(t)$ in (2.1) or one of the coefficients $a_i(t)$ in (2.2) has a pole is the *singular* point for the equation. In the case of local situation we shall assume that $t_* = 0$.

The singular point $t = 0$ of Eq. (2.1) or (2.2) is called *regular* if any its solution $\phi(t)$ has at most polynomial growth in any sector with vertex at $t = 0$. It means that

$$|\phi(t)| < C_N/|t|^N, \quad |t| \to 0,\ \alpha < \arg t < \beta.$$

Otherwise the singular point is called *irregular*.

The division of the singular points of systems (2.1) into regular and irregular is very rough. Our aim is to classify such systems with respect to equivalence relations defined below.

DEFINITION 2.2. Two local differential systems $\dot{z}_1 = A_1(t)z_1$ and $\dot{z}_2 = A_2(t)z_2$ are called *holomorphically equivalent* near the singular point $t = 0$ if there exists a holomorphic matrix $H(t)$ such that, after the change $z_2 = H(t)z_1$, the first system is transformed to the other system. In other words,

$$A_2 = \dot{H}H^{-1} + HA_1H^{-1}.$$

These systems are called *meromorphically equivalent* (respectively, *formally equivalent* or *formally meromorphically equivalent)* if there exists a meromorphic matrix $H(t)$ (respectively a formal series $H(t) \sim \sum_{j=0}^{\infty} H_j t^j$ or $\sum_{j=-m}^{\infty} H_j t^j$) which transforms one system to another system. In the formal cases this holds at the level of formal expansions of these systems in powers of t.

2.1. *Regular singularities*

We begin the study of singularities of the meromorphic differential equations with the one-dimensional phase space, $n = 1$. It means that we have the equation

$$t^r \dot{z} = a(t)z$$

where $a(t)$ is an analytic function near 0.

If $r = 0$ then the solutions are analytic; in fact, the point $t = 0$ is not singular for this equation.

If $r > 0$ then we assume that the coefficient $a_0 \neq 0$ in the expansion $a(t) = a_0 + a_1 t + \cdots$. The general solution is written in the form

$$z(t) = C \cdot \exp\left[\int^t a(s)s^{-r}\,\mathrm{d}s\right].$$

If $r = 1$ then we get $z(t) = Ct^{a_0} \times \Psi(t)$, where Ψ is an analytic function. This means the regularity of the singular point.

If $r > 1$ then $z(t) = C\mathrm{e}^{R(1/t)}t^b \times \Psi(t)$, Ψ analytic, where

$$R(x) = \frac{a_0}{1-r}x^{r-1} + \frac{a_1}{2-r}x^{r-2} + \cdots - a_{r-2}x,$$

$b = a_{r-1}$. Here the singularity is irregular, because for $\mathrm{Re}(a_0 t^{1-r}) < 0$ the solution diverge faster than any power of t. We proved the following

PROPOSITION 2.3. *If $n = 1$ then the singular point of Eq.* (2.1) *is regular if and only if the function $A(t)$ has pole of order exactly* 1.

In general, Eq. (2.1) *is analytically equivalent to the equation $t^r \dot{z} = (\sum_0^{r-1} a_j t^j)z$.*

Consider now the case of n-dimensional system with the following singularity

$$t\dot{z} = Az,$$

where A is a constant matrix. The fundamental matrix of solutions of this system is

$$t^A = \mathrm{e}^{A\ln t},$$

which grows at most polynomially (regularity). This fact is generalized in the following way.

PROPOSITION 2.4. *If $A(t) = A_0/t + A_1(t)$, where $A_0 = \mathrm{const} \neq 0$ and $A_1(t)$ is a holomorphic matrix-valued function, then the point $t = 0$ is regular.*

PROOF. We put $t = \rho\mathrm{e}^{\mathrm{i}\theta}$, where $\theta = \mathrm{const}$ and ρ tends to 0. Let $\phi(t) \not\equiv 0$ be a solution, and $r(\rho) = |\phi(t)|_{\theta=\mathrm{const}}|$.

From the identity $\frac{\partial \phi}{\partial \rho} = \mathrm{e}^{\mathrm{i}\theta}\dot{\phi} = (\tilde{A}(t)/\rho)\phi$ (where $\tilde{A}$ is holomorphic) we get the inequality $\frac{\mathrm{d}r}{\mathrm{d}\rho} > -\frac{Kr}{\rho}$ for $0 < \rho < \rho_0$, with some constant K and ρ_0.

From this we see that the graph of the function $r(\rho)$ must lie in the domain $\{r < \rho^{-K}\}$ for ρ near 0. □

DEFINITION 2.5. System (2.1), i.e. $\dot{z} = A(t)z$, has singularity of the *Fuchs type* at $t = 0$ if $A(t)$ has simple pole at 0. Equation (2.2), i.e. $x^{(n)} + \cdots + a_n(t)x = 0$, has singularity of the *Fuchs type* at $t = 0$ if all the functions $t^j a_j(t)$ are holomorphic near 0.

Proposition 2.4 says that, if the system (2.1) has singularity of the Fuchs type, then this singularity is regular. The following example shows that the converse is not true.

EXAMPLE 2.6. The *Euler equation*

$$t^n x^{(n)} + c_1 t^{n-1} x^{(n-1)} + \cdots + c_n x = 0,$$

where c_i are constants, by means of the change $t = \mathrm{e}^u$, $\frac{\mathrm{d}}{\mathrm{d}t} = \mathrm{e}^{-u}\frac{\mathrm{d}}{\mathrm{d}u}$, $\frac{\mathrm{d}^2}{\mathrm{d}t^2} = \mathrm{e}^{-2u}(\frac{\mathrm{d}^2}{\mathrm{d}u^2} - \frac{\mathrm{d}}{\mathrm{d}u}), \ldots$ is reduced to the equation

$$\frac{\mathrm{d}^n x}{\mathrm{d}u^n} + d_1 \frac{\mathrm{d}^{n-1} x}{\mathrm{d}u^{n-1}} + \cdots + d_0 x = 0$$

with constant coefficients. Its general solution has the form $x = \sum a_{\alpha,k} \mathrm{e}^{\alpha u} u^k = \sum a_{\alpha,k} t^\alpha (\ln t)^k$. Thus the point $t = 0$ is regular. On the other hand, if we rewrite the Euler equation in form of the linear system

$$\dot{z} = \begin{pmatrix} 0 & 1 & 0 & \ldots & 0 \\ 0 & 0 & 1 & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ -c_n/t^n & -c_{n-1}/t^{n-1} & \ldots & \ldots & -c_1/t \end{pmatrix} z$$

(where $z_1 = x, z_2 = \dot{x}, \ldots$) then the corresponding matrix $A(t)$ has non-simple pole.

In the case of linear equation of n-th order the situation is much more clear.

THEOREM 2.7. *The singular point $t = 0$ for Eq.* (1.2) *is regular if and only if it is of Fuchs type.*

Before proof of this theorem we need one important definition.

DEFINITION 2.8. Let t_0 be a non-singular point of Eq. (2.1) or (2.2), defined near the singularity $t = 0$. Let $\mathcal{V}$ be the space of its solutions defined near t_0. As t turns around the point 0, with the beginning and end at t_0, the solutions are prolonged analytically and define the *monodromy operator* $\mathcal{M} : \mathcal{V} \to \mathcal{V}$: if $\phi(t)$ is a (local) solution then $\mathcal{M}\phi(t) = \phi(\mathrm{e}^{2\pi \mathrm{i}} t)$.

Let $\phi_1(t), \dots, \phi_n(t)$ be a basis of $\mathcal{V}$. This basis defines the *fundamental matrix* $\mathcal{F} = (\phi_1, \dots, \phi_n)$ in the case (2.1) and

$$\mathcal{F} = \begin{pmatrix} \phi_1 & \dots & \phi_n \\ \vdots & \ddots & \vdots \\ \phi_1^{(n-1)} & \dots & \phi_n^{(n-1)} \end{pmatrix}$$

in the case (2.2). Then the monodromy operator, written in this basis, is the *monodromy matrix* M satisfying $\mathcal{F}(t)M = \mathcal{F}(\mathrm{e}^{2\pi \mathrm{i}}t)$. Here the matrix M depends on the choice of $\mathcal{F}$ but locally does not depend on the point t_0.

PROOF OF THEOREM 2.7. (We follow the proof of Theorem 5.2 in the book of E. Coddington and N. Levinson [24].)

Assume that the Fuchs conditions, i.e. all $t^j a_j(t)$ are holomorphic, hold. We are going to show that the singularity $t = 0$ is regular.

Following the latter example we perform a transformation reducing equation (2.2) to a system (1.1) with the Fuchs type singularity. Then Proposition 2.4 will give us the regularity property.

The change is following

$$z_1 = x, \quad z_2 = (t\,\mathrm{d}/\mathrm{d}t)x, \quad z_3 = (t\,\mathrm{d}/\mathrm{d}t)^2 x, \dots, z_n = (t\,\mathrm{d}/\mathrm{d}t)^{n-1}x.$$

It gives $\dot{z}_1 = (1/t)z_2$, $\dot{z}_2 = (1/t)z_3, \dots, \dot{z}_{n-1} = (1/t)z_n$ and $z_j = t^j x^{(j)}$ plus a combination of $t^k x^{(k)}$, $k < j$. Thus $t^j x^{(j)}$ can be expressed as linear combination of z_k, $k \leqslant j$.

The last equation from the promised system is $\dot{z}_n = \frac{\mathrm{d}}{\mathrm{d}t}(t^{n-1}x^{(n-1)}) +$ plus combination of $\dot{z}_i$, $i < n$. The term $\frac{\mathrm{d}}{\mathrm{d}t}(t^{n-1}x^{(n-1)})$ contains $(n-1)z_n/t$ and $t^{n-1}x^{(n)} = -t^{n-1}\sum a_j x^{(n-j)} = -t^{-1}\sum (a_j t^j)(x^{(n-j)}t^{n-j})$. The functions $a_j t^j$ are holomorphic by the assumption and $x^{(n-j)}t^{n-j}$ are expressed by means of z_i's. All this shows that $t\dot{z}_n$ is analytic in t and z.

Assume that $t = 0$ is a regular point. We want to show that the functions $b_j(t) = a_j(t)t^j$ are analytic.

We use the monodromy operator. If $\mathcal{F}$ is the fundamental matrix and $\mathcal{F} \to \mathcal{F}M$ is the monodromy operation and $G(t) = t^{-\ln M/2\pi \mathrm{i}}$, then the matrix-function $\mathcal{F}G$ is univalent. By the regularity of $\mathcal{F}$ it is a meromorphic function. Thus $\mathcal{F} =$ (meromorphic matrix) $\times$ $t^{\ln M/2\pi \mathrm{i}}$.

The monodromy matrix M has always some (left) eigenvector $v = (v_1, \dots, v_n)$, $vM = \lambda v$. Using it we can find a solution $\phi(t) = \sum v_i \phi_i$ of the form $t^\mu \times$ (analytic function), where the exponent μ satisfies $\mathrm{e}^{2\pi \mathrm{i}\mu} = \lambda$. Note that the function $\phi(t)$ does not contain logarithms in its expansion.

Other solutions are searched for in the form $x = \phi \cdot y$. For $u = \dot{y}$ we obtain an equation of order $n - 1$.

Indeed, if we define the differential operator $P = (\mathrm{d}/\mathrm{d}t)^n + \sum a_j(\mathrm{d}/\mathrm{d}t)^{n-j}$ then $P(\phi y) = P(\phi) \cdot y$ plus expressions depending on $\dot{y}$. The original equation for x gives an equation is of the form

$$\sum c_j(t)u^{(j)} = 0,$$

where $c_0 = a_0 = 1$ and

$$c_j = a_j + \text{const} \cdot a_{j-1} \cdot \dot{\phi}/\phi + \text{const} \cdot a_{j-2} \cdot \ddot{\phi}/\phi + \cdots, \quad \phi^{(l)}/\phi \sim \text{const} \cdot t^{-l}.$$

Next we use induction with respect to the order n. In the case $n = 1$ the statement was proved in Proposition 2.3; the regularity implies Fuchs property.

Assume that we know that any regular equation of order $n - 1$ satisfies the Fuchs conditions and consider our system.

Let ψ_i be the system of independent solutions of the equation for u. Then $\psi_i = \frac{\mathrm{d}}{\mathrm{d}t}(\phi_i/\phi)$, where ϕ_i are independent solutions of the equation for x. Because all ϕ_i are regular (by assumption) and $\phi \sim t^{\mu}$ then also $\psi_i(t)$ behave regularly. Therefore the equation for u has regular singularity at $t = 0$. By the induction assumption the coefficients $c_j(t)$ have good behavior, $c_j t^j$ are analytic. Because of the above relation between a_j's and c_k's we find that also the functions $a_j t^j$ are holomorphic. □

PROPOSITION 2.9. *The point $t = 0$ is a regular singular point for the system $\dot{z} = A(t)z$ if and only if this system is meromorphically equivalent to the system $\dot{z} = (C/t)z$ where the matrix C is the logarithm of the monodromy matrix M, $M = \mathrm{e}^{2\pi \mathrm{i} C}$.*

PROOF. Let $\mathcal{F}(t)$ be the fundamental matrix of the system with the matrix A. Define $H(t) = \mathcal{F}(t)t^{-C}$. It is univalent and meromorphic matrix-valued function (by the regularity). It is easy to check that $H(t)$ is the conjugating transformation.

The reverse implication is obvious. □

Our next aim is to improve the latter result. Let us rewrite system (2.1) in the form

$$t^r \dot{z} = B(t)z, \quad B(0) \neq 0, \tag{2.4}$$

with an analytic matrix $B(t)$. This system is associated with the following autonomous system in the extended phase space

$$z' = B(t)z, \quad t' = t^r, \tag{2.5}$$

where $' = \mathrm{d}/\mathrm{d}\tau$. Note that the graphs of solutions to Eq. (2.4) form the phase curves of Eq. (2.5). Assume also that $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of the matrix $B(0)$.

The point $z = 0$, $t = 0$ is an equilibrium point of system (2.5). If $r = 1$, i.e. in the Fuchs case, then the eigenvalues of the linear part at $(0, 0)$ of system (2.5) are $\lambda_1, \ldots, \lambda_n, 1$. If $r > 1$, then the eigenvalues of system (2.5) are $\lambda_1, \ldots, \lambda_n, 0$.

DEFINITION 2.10. The system $\lambda_1, \dots, \lambda_n$ of eigenvalues of $B(0)$ is *resonant* if:
(a) $\lambda_i - \lambda_j \in \mathbb{Z}$ for some $i \neq j$ in the case $r = 1$;
(b) $\lambda_i - \lambda_j = 0$ for some $i \neq j$ in the case $r > 1$.

Now we use some results from the theory of normal forms for germs of analytic vector fields $(\mathbb{C}^n, 0)$

$$\dot{x} = V(x) = Ax + \cdots,$$

where A is a constant matrix of the linearization of the vector field at 0 (with the eigenvalues $\mu_1, \dots \mu_n$). The *Poincaré–Dulac theorem* (Theorem 3.17 from the next section) says that:

there exists a change $x \to y = G(x)$, where $G(x)$ is given by formal power series, which transforms the above vector field to a formal vector field $\dot{y} = W(y)$, such that the expansion of each component $W_j(y)$ of W is of the form

$$W_i(y) = \mu_i y_i + \sum a_{i,k} y^k$$

and the summation runs over multiindices $k = (k_1, \dots, k_n)$ which satisfy the resonance relations

$$\mu_i = \mu_1 k_1 + \cdots + \mu_n k_n.$$

Moreover, if the components $V_1(x), \dots, V_k(x)$ are linear with respect to the variables $x_1, \dots, x_k$ then also the components $G_1(x), \dots, G_k(x)$ and $W_1(y), \dots, W_k(y)$ are linear with respect to suitable variables.

We apply this result to vector field (2.5), where we use changes of the form $(z, t) \to (H(t)z, t)$. (We note that the idea to apply the Poincaré–Dulac theorem to linear systems was used firstly in the review article by Arnold and Il'yashenko [5].) The reader can notice that the resonant relations from the Poincaré–Dulac theorem correspond to the relations between the eigenvalues of the matrix $B(0)$ defined in Definition 2.10. The corresponding resonant terms in the normal form are

$$t^l z_j e_i,$$

i.e. if $\lambda_i = \lambda_j + l$, where $(e_1, \dots, e_n)$ is the eigenvector basis for the matrix $B(0)$.

COROLLARY 2.11. *If the singular point $t = 0$, with $r = 1$ or $r > 1$, is non-resonant then the Poincaré–Dulac theorem says that system* (2.4) *is formally equivalent to the system $t^r \dot{z} = B(0)z$.*

On the other hand, Proposition 2.9 says about the meromorphic equivalence. But the formal equivalence means that, in the meromorphic matrix $H(t) = H_{-d} t^{-d} + \cdots$, all the terms with negative power of t vanish. This gives the following result.

THEOREM 2.12. *The system $t\dot{z} = B(t)z$ with non-resonant Fuchsian singular point is analytically equivalent to $t\dot{z} = B(0)z$.*

Of course, in the above theorem we can assume that the matrix $B(0)$ is diagonal. Hence the normal form variables are completely separated. In the resonant case we can divide the eigenvalues into groups such that:

- the differences $\lambda_i - \lambda_j \notin \mathbb{Z}$ for eigenvalues from different groups,
- the differences $\lambda_i - \lambda_j \in \mathbb{Z}$ for eigenvalues from the same group.

We order the eigenvalues in each group such that the differences $\lambda_i - \lambda_j$ are non-negative integers for $j < i$, $\lambda_i - \lambda_j \in \mathbb{Z}_+$. We have the following result whose proof is postponed to Subsection 2.3 below.

THEOREM 2.13. *If a Fuchsian singular point is resonant then it is analytically equivalent to a system of the form*

$$t\dot{z}_i = \lambda_i z_i + \sum_{\lambda_i - \lambda_j \in \mathbb{Z}_+} a_{ij} t^{\lambda_i - \lambda_j} z_j, \quad i = 1, \dots, n, \ a_{ij} = \text{const.}$$

REMARK 2.14. The system from the thesis of Theorem 2.13 can be easily integrated. Its general solution has the form $z_i(t) = t^{\lambda_i} \times$ (polynomial of $\log t$). For more details we refer the reader to [24].

REMARK 2.15. If a singular point $t = 0$ is regular for Eq. (2.2) and $a_i(t) = \nu_i t^{-i} + \cdots$ then we can seek solutions ϕ such that $\phi(t) \sim Ct^{\lambda}$. We arrive to the equation

$$P(\lambda) = \lambda(\lambda - 1) \cdots (\lambda - n + 1) + \lambda \cdots (\lambda - n + 2) \cdot \nu_1 + \cdots + \nu_n = 0$$

which is called the *defining equation* for (2.2).

The defining equation corresponds to the characteristic equation for the matrix $B(0)$ from the system (2.4). Namely, we apply the transformation of Eq. (2.2) to a Fuchsian system from the proof of Theorem 2.7. This Fuchsian system has the form (2.4) with $r = 1$.

The roots of the defining equation allow to determine the first terms of the asymptotic of solutions of the differential equation.

If the system $(\lambda_i, \dots, \lambda_n)$ of roots is not resonant in the sense of Definition 2.10 (for $r = 1$) then the general solution is a linear combination of functions of the form $\phi_i(t) = t^{\lambda_i} \times$ (analytic function). Otherwise we have also functions of the form $t^{\lambda_i} \times (\log t)^j \times$ (analytic function).

EXAMPLE 2.16. Consider the Gauss hypergeometric equation (2.3), i.e. $t(t-1)\ddot{x} + [(\alpha + \beta + 1)t - \gamma]\dot{x} + \alpha\beta x = 0$. It has singular points at $t = 0$, $t = 1$ and also at $t = \infty$, all Fuchsian.

The defining equation at $t = 0$ is $\lambda(\lambda - 1 + \gamma) = 0$ and the two linearly independent solutions are $\phi_1 = F(\alpha, \beta; \gamma; t)$ and $\phi_2 = t^{1-\gamma} F(\alpha - \gamma + 1, \beta - \gamma + 1; 2 - \gamma; t)$, where $F(\alpha, \beta; \gamma; t) = \sum_{n=0}^{\infty} \frac{(\alpha)_n (\beta)_n}{(\gamma)_n n!} t^n$, $(a)_n = a(a+1) \cdots (a + n - 1)$, is the so-called the *hypergeometric series*. This holds when γ is not integer and for integer γ one of these functions is not defined. For example, when $\gamma = 0$ the solution ϕ_2 is the same but $\phi_1 = tF(\alpha, \beta; 1; t) \cdot \log t + G(t)$, where $G(t)$ is some uniquely defined series.

For $t = 1$ the defining equation is $\lambda(\lambda - \gamma + \alpha + \beta) = 0$ and the (generically) independent solutions are $F(\alpha, \beta; \alpha + \beta + 1 - \gamma; 1 - t)$ and $t^{\gamma - \alpha - \beta} F(\gamma - \beta, \gamma - \alpha; 1 - \alpha - \beta + \gamma; 1 - t)$.

Near $t = \infty$ one rewrites the Gauss equation in the local variable $\tau = 1/t$. The defining equation is $(\lambda - \alpha)(\lambda - \beta) = 0$ and the functions $\tau^\alpha F(\alpha, 1 - \gamma + \alpha; 1 + \alpha - \beta; \tau)$, $\tau^{-\beta} F(\beta, 1 - \gamma + \beta; 1 + \beta - \alpha; \tau)$ constitute the basis of the space of solutions.

2.2. *Irregular singularities*

Firstly we find a formal normal form for linear systems (2.4) with an irregular singularity.

THEOREM 2.17. *If $r > 1$ and $B(0)$ is non-resonant then the system $t^r \dot{z} = B(t)z$ is formally equivalent to the system*

$$t^r \dot{w} = D(t)w, \tag{2.6}$$

where the matrix $D(t)$ is diagonal, $D = \operatorname{diag}(d_1(t), \dots, d_n(t))$, and $d_i(t)$ are polynomials of degree at most $r - 1$.

PROOF. By the Poincaré–Dulac theorem all the terms $t^k z_j e_i$, $i \neq j$, can be canceled (because they are non-resonant). There remain only the terms $t^k z_i e_i$ which are diagonal. Next one applies Proposition 2.3 to each component. □

If we write $D(t)t^{-r} = D_r t^{-r} + D_{r-1} t^{-r+1} + \dots + D_2 t^{-2} + E t^{-1}$, where D_j and E are diagonal matrices, then the formal fundamental matrix of the system from Theorem 2.17 takes the form $\mathcal{F}(t) = \widehat{G}(t) t^E \exp[\sum D_j t^{j+1}/(j+1)]$, where $\widehat{G}$ is a formal power series.

In the resonant case there exists also a diagonal formal normal form, but in another category. One should change the local ring $\mathbb{C}[[t]]$ (of formal power series in t) by the ring $\mathbb{C}[[t^{1/b}]]$, where b is some positive integer.

EXAMPLE 2.18. (See [35,82].) The system

$$\dot{z}_1 = (1/t) z_3, \quad \dot{z}_2 = (1/t^2) z_1, \quad \dot{z}_3 = (1/t^2) z_2$$

is of the form $t^2 \dot{z} = B(t)z$, where the matrix $B(0)$ is nilpotent. The substitution $y_1 = t^{-1/3} z_1$, $y_2 = z_2$, $y_3 = t^{1/3} z_3$ gives

$$\dot{y}_1 = t^{-5/3} y_3 - (1/3t) y_1, \quad \dot{y}_2 = t^{-5/3} y_1, \quad \dot{y}_3 = t^{-5/3} y_2 + (1/3t) y_3.$$

Thus we get $\dot{y} = (t^{-5/3} F + t^{-1} E) y$, where

$$F = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \qquad E = \operatorname{diag}(-1/3, 0, 1/3).$$

We see that the leading matrix F has three distinct eigenvalues, the cubic roots of -1. Transforming it to the diagonal form and applying the series of transformations from the proof of Theorem 2.17, which are power series in $t^{1/3}$, we can diagonalize also the remaining part of the system for y.

A general result concerning normal forms in the case of resonant irregular singular point belongs to M. Hukuhara H. Turrittin and A. Levelt and is formulated in the next theorem.

THEOREM 2.19. (See [39,81,46].) *If $t = 0$ is an irregular singular point of the system $\dot{z} = A(t)z$ then there exist a positive integer b and a change $y = H(t^{1/b})z$ in the class of formal series in $s = t^{1/b}$, such that H transforms the system for z to a system of the form*

$$\dot{y} = (D_m t^{-m/b} + D_{m-1} t^{-(m-1)/b} + \cdots + D_{b+1} t^{-(b+1)/b} + E t^{-1}) y \tag{2.7}$$

where the matrices D_j and E are diagonal.

Two forms (2.7) *with D_j, E and D'_j, E' are formally equivalent* (*over* $\mathbb{C}[[t^{1/b}]]$) *iff the matrices D_j and D'_j and E and E' are mutually spontaneously conjugated by means of some matrix from* $\mathrm{GL}(n, \mathbb{C})$.

REMARK 2.20. In the variable $s = t^{1/b}$ system (2.7) takes the form

$$\mathrm{d}y/\mathrm{d}s = b(D_m s^{b-m-1} + \cdots + D_{b+1} s^{-2} + E s^{-1}) y.$$

The number $r_1 = \frac{m}{b}$ is called the *Katz invariant* and the smallest integer b is called the *ramification index*.

PROOF OF THEOREM 2.19. (We follow the papers [72] of Y. Sibuya and [82] of V. Varadarajan and the book [89].)

Assume that we have $t^r \dot{z} = B(t)z$.

1. Repeating the proof of Theorem 2.17 we show that the division of the matrix $B(0)$ into diagonal blocks corresponding to different eigenvalues λ_i can be prolonged to a formal splitting of the system into several independent systems, which are characterized by having only one eigenvalue.

2. Let $\lambda_1 = \cdots = \lambda_n = \lambda$. The change $z = \mathrm{e}^{\lambda/(1-r)t^{r-1}} y$ leads to a system $t^r \dot{y} = B(t)y$ (with new $B(t)$) such that

$$B(0) = \begin{pmatrix} 0 & d_1 & \ldots & 0 \\ 0 & 0 & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots \\ 0 & 0 & \ldots & d_{n-1} \\ 0 & 0 & \ldots & 0 \end{pmatrix},$$

where $d_i = 0, 1$

3. Assume that all $d_j = 1$. We introduce the variables $u_1 = y_1$, $u_2 = t^r \dot{u}_1, \ldots, u_n = t^r \dot{u}_{n-1}$. Then we obtain a system $t^r \dot{u} = B(t)u$ such that

$$B(t) = \begin{pmatrix} 0 & 1 & \ldots & 0 \\ 0 & 0 & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots \\ 0 & 0 & \ldots & 1 \\ b_1(t) & b_2(t) & \ldots & b_n(t) \end{pmatrix},$$

where each $b_j(t) = \mathrm{O}(t)$.

Now the substitution $u_j = t^{a_j} v_j$, with suitable rational exponents a_j, leads to the equation $\dot{v} = (t^{-\alpha} C + \cdots)v$ where the matrix C has the form like the matrix $B(0)$ but with at least one constant $b_j(0) \neq 0$. This means that C has at least one non-zero eigenvalue and we can apply the induction with respect to the dimension of the eigenspace.

4. If some of the d_i's in the matrix $B(0)$ (from the point 2) are equal to zero then, using the change $y \to u$ analogous as in the point 3, we reduce the matrix $B(t)$ to a matrix

$$\begin{pmatrix} B_1 & E_{12} & \ldots \\ E_{21} & B_2 & \ldots \\ \ldots & \ldots & \ldots \end{pmatrix},$$

such that $B_j = B_j(t)$ are of the form from the point 3 and

$$E_{ij} = \begin{pmatrix} 0 & \ldots & 0 \\ e_1(t) & \ldots & e_s(t) \end{pmatrix},$$

where $e_k(t)$ are functions. It means that most of the rows of $B(t)$ consist of zeroes and the other rows are composed of functions $b_k(t)$ and $e_l(t)$.

One can show that, after applying a suitable change $u \to v$ of the same form as in the point 3, we obtain $\dot{v} = (t^{-\alpha} C + \cdots)v$ where either:

(i) the matrix C has a non-zero eigenvalue (if some $b_k(0)$ becomes $\neq 0$ or some $e_l(0) \neq 0$ in some E_{ij}, $i > j$), or

(ii) the matrix C is nilpotent but its Jordan normal form contains more non-zero d_j's than in the matrix $B(0)$ from the point 2 (here some $e_l(0) \neq 0$ in a $E_{i,j}$, $i < j$), or

(iii) none of the above.

In the cases (i) and (ii) we apply the induction with respect to the dimension of the eigenspace and to the number of non-zero d_j's. (See also [82].)

5. The case (iii) occurs when some supposedly non-trivial row of $B(t)$ from the point 4 vanishes identically; (such phenomenon has infinite codimension). Note that all the changes used in the above point are polynomial in $s = t^{1/b}$. Therefore the system becomes analytically separated, although the first diagonal matrix D_m from the thesis of Theorem 2.19 has coinciding eigenvalues. □

Having solved the problem of formal classification of meromorphic systems with irregular singularity we pass to the analytic classification. It turns out that formal solutions of such systems (or higher order equations) can be divergent. The series from the formal normal forms are only asymptotic.

EXAMPLE 2.21. (See [34].) The series $\sum k!t^k$ formally satisfies the equation $t^2\ddot{x} + (3t-1)\dot{x} + x = 0$ but is divergent.

In what follows we assume that the eigenvalues of the matrix D_m from the thesis of Theorem 2.19 are different. From the point 5 of the above proof it follows that it is sufficient for the analytic classification.

We apply the change of time $t \to t^{1/b}$, and the new time we again denote by t. We apply a polynomial change $z \to \sum_{j=0}^{N} H_j(t)z$, which reduces the polar part of the matrix $A(t) = B/t^r$ to the diagonal form. Thus we get a system $t^r\dot{z} = B(t)z$, where $B(t) = D(t) + O(t^r)$ (we do not change notation of B) and whose formal normal form is (2.6), i.e. $t^r\dot{y} = D(t)y$ with diagonal and polynomial $D(t)$.

Recall that the eigenvalues of $B(0) = D(0)$ satisfy the condition (see the remark above)

$$\lambda_i \neq \lambda_j, \quad i \neq j.$$

If $i \neq j$ then the rays in the complex t plane defined by

$$\operatorname{Re}\bigl[(\lambda_i - \lambda_j)t^{1-r}\bigr] = 0$$

are called the *rays of division corresponding to the pair* (λ_i, λ_j). The following theorem of H. Poincaré is principal in this subsection. Its proof is sketched in Appendix.

THEOREM 2.22. (See [67].) *Let* $S = \{|t| < \epsilon, \alpha < \arg t < \beta\}$ *be a sector in the* t*-plane not containing two rays of division* (*corresponding to any pair* (λ_i, λ_j)). *Then there exists a unique matrix function* $H(t) = I + O(t)$ *analytic in* S *which transforms the system* $t^r\dot{z} = B(t)z$ *to the formal normal form system* (2.6).

Let S_1 and S_2 be two adjacent sectors (i.e. with non-empty intersection) satisfying the assumptions of Theorem 2.22. Let H_{S_1} and H_{S_2} be the corresponding operators guaranteed by this theorem. From Theorem 2.17 it follows that these two matrix-functions have the same Taylor expansions. Because these Taylor expansions are only asymptotic, then H_{S_i} are generally different in the intersection of the two sectors.

One defines the matrix-function

$$G_S(t) = H_{S_1}H_{S_2}^{-1}, \quad t \in S = S_1 \cap S_2.$$

Let $\mathcal{L}_S$ be the space of solutions of the normalized system. The transformation induced by G_S transforms solutions from $\mathcal{L}_S$ to solutions from the same space. Therefore it defines certain automorphism $\mathcal{C}_S : \mathcal{L}_S \to \mathcal{L}_S$.

If we choose a basis of $\mathcal{L}_S$ in the form

$$\phi_j = a_j(t)e_j, \quad a_j(t) = \exp\bigl[\lambda_j t^{1-r}/(1-r) + \cdots\bigr],$$

where (e_j) is the standard basis of $\mathbb{C}^n$, then the operator $\mathcal{C}_S$ expressed in this basis is a constant matrix $C_S = (c_{ij})$.

DEFINITION 2.23. The operator $\mathcal{C}_S$ which is called the *Stokes operator* and the matrix C_S is called the *Stokes matrix*.

If $\psi_i = G_S(t)\phi_i(t) = \mathcal{C}_S\phi_i = \sum_j c_{ij}\phi_j$ then the matrix G_S acts as follows: $G_S e_i = \psi_i/a_i(t)$. We have

$$(G_S)_{ij} = a_i^{-1}(t)\cdot c_{ij}\cdot a_j(t) = c_{ij}\cdot \exp\bigl[(\lambda_j-\lambda_i)t^{1-r}/(1-r)+\cdots\bigr].$$

PROPOSITION 2.24. *The matrix $G_S(t)$ preserves the normalized system* (2.6) *and has the property $G_S(t) = I + O(t^N)$ as $t\to 0$ for any N.*

This implies that: $c_{ii} = 1$ *and* $c_{ij} = 0$ *when* $\mathrm{Re}(\lambda_i - \lambda_j)t^{1-r} \to -\infty$ *as* $t \to 0$. *Therefore, after suitable ordering of the basis (e_i), we obtain that the matrix C_S is unipotent upper triangular.*

The system of Stokes operators can be naturally described using the cohomology language. Take the circle S^1, which we treat as the circle $\{r=0\}$ in $\mathbb{R}_+\times S^1 = \{(r,\theta)\}$ where r,θ are the polar coordinates of the $t = r\mathrm{e}^{\mathrm{i}\theta}\in\mathbb{C}$. If $U\subset S^1$ is an open arc then we associate with a germ of sector $S = S_U$ in $(\mathbb{C},0)$ with base at U.

DEFINITION 2.25. The *Stokes sheaf St* is defined by the presheaf of groups $\mathrm{St}(U)$, $U\subset S^1$ (as above), where $\mathrm{St}(U)$ consists of matrix-functions $S = S_U \ni t \to G_U(t)$ satisfying the following properties:

- $G_U(t)\sim I$,
- $G_U(t)$ preserve the normalized system.

REMARK 2.26. St is not a standard sheaf with which we are acquainted. The groups $\mathrm{St}(U)$ are (generally) non-Abelian groups and the Čech coboundary operator, Čech cocycles and Čech cohomologies must take proper meaning. Here we recall the definition of the first cohomology group of sheaves $\mathcal{F}$ of non-Abelian groups.

The cochains are the same as in the Abelian theory. In particular, a 0-cochain associated with a covering $\mathcal{U} = \{U\}$ is a system $(G_U)_{U\in\mathcal{U}}$ with $G_U\in\mathcal{F}(U)$. 1-cochains are systems (G_{UV}) with $G_{UV}\in\mathcal{F}(U\cap V)$ such that $G_{VU} = G_{UV}^{-1}$. This 1-cochain is a cocycle iff $G_{UV}G_{VW}G_{WU} = e$. Two 1-cochains (G_{UV}) and (G'_{UV}) are equivalent iff there is 0-cochain (K_U) such that

$$G'_{UV} = K_U G_{UV} K_V^{-1}.$$

The first cohomology group $H^1(\mathcal{F},\mathcal{U})$ is defined as the set of classes of 1-cocycles with respect to the this equivalence. Such cocycles with $G_{UV}\in\mathrm{St}(U\cap V)$ are called the *Stokes cochains*.

Next one should takes the direct limit with respect to the coverings, but usually fine finite coverings are sufficient.

A Stokes cochain can be interpreted as a cocycle of Stokes matrices. If $\mathcal{F}_0$ is the fundamental matrix of the normalized system, then

$$C_{UV} = \mathcal{F}_0 G_{UV}\mathcal{F}_0^{-1}$$

is a cocycle of constant matrices. Two Stokes cocycles (C_{UV}) and (C'_{UV}) are called equivalent iff there exists a system (C_U) of constant matrices such that $C'_{UV} = C_U^{-1} C_{UV} C_V$.

If we calculate the cohomology group of the Stokes sheaf using C_{UV} then we see that it is finite-dimensional.

Now we pass to the description of moduli of analytic classification of linear systems with irregular singular point. We fix the normalized system (2.6), which we denote by $\mathcal{S}_0$, and consider the space $\mathcal{M} = \mathcal{M}_D$ of systems $\mathcal{S}: t^r \dot{z} = B(t)$ which are formally equivalent to $\mathcal{S}_0$. On the space $\mathcal{M}$ we introduce the following equivalence relation (compare Definition 2.2):

$\mathcal{S} \sim \mathcal{S}'$ iff there is a matrix function $H(t)$ holomorphic in a (*whole*) *neighborhood of $t = 0$ and realizing equivalence between $\mathcal{S}$ and $\mathcal{S}'$.*

The following fundamental in this theory result was proved by B. Malgrange and Y. Sibuya and is called also the *Malgrange–Sibuya Theorem.*

THEOREM 2.27. (See [52,73].) *The space of equivalence classes defined above coincides with the first cohomology group of the circle with coefficients in the Stokes sheaf. In other words, the group $H^1(S^1, St)$ parameterizes the orbits of the action of the group of analytic equivalences on the space of germs of meromorphic linear systems with fixed formal normal form.*

This property holds in the non-resonant case as well as in the resonant case with the formal normal form the thesis of Theorem 2.19.

PROOF. Let $\mathcal{M}$ be the above space of the equivalence classes. We define a natural map from $\mathcal{M}$ to $H^1(S^1, St)$.

Take a system $\mathcal{S} \in \mathcal{M}$. By the sectorial normalization theorem there exists a covering of a neighborhood of the point $t = 0$ by sectors S_i such that $\mathcal{S}$ is transformed to $\mathcal{S}_0$ by means of holomorphic maps $H_i(t)$ in S_i. Let U_i be the bases of the sectors S_i. Then the family of operators $H_i H_j^{-1}$ defines a Stokes cocycle associated with the covering $\{U_i\}$.

If two systems $\mathcal{S}$ (defining a cocycle $H_i H_j^{-1}$) and $\mathcal{S}'$ (defining a cocycle $H'_i (H'_i)^{-1}$) are equivalent by means of a holomorphic matrix $H(t)$, then $H'_i = H_i H$ (by the uniqueness in Theorem 2.22) and the cocycles define the same cohomology class. This gives the map $\Phi : \mathcal{M} \to H^1(S^1, St)$.

The injectivity of the map Φ is simple. If $H'_i (H'_j)^{-1} = G_i^{-1} H_i H_j^{-1} G_j$ then $H_i^{-1} G_i H'_i = H_j^{-1} G_j H'_j$. The latter matrix is thus univalent and defines a holomorphic conjugation between the systems $\mathcal{S}'$ and $\mathcal{S}$.

The surjectivity of the map Φ is the most difficult part of the proof. Here we follow [6], but we omit the details. Probably the first proof of this surjectivity was given by G.D. Birkhoff [11].

Let $(G_{ij}) = (G_{U_i U_j})$ be a cocycle with values in the Stokes sheaf. If we could find a system $H_i = I + O(t)$ of holomorphic matrices in sectors S_i (with bases U_i) and such that $G_{ij} = H_j^{-1} H_i$, then this would give us a corresponding meromorphic linear equation $\dot{z} = Az$.

Indeed, let $\mathcal{F}_0$ be a fundamental matrix for the normalized system $\dot{z} = A_0 z$, $A_0 = t^{-r}C(t)$. The matrices $\mathcal{F}_i = H_i\mathcal{F}_0$ are the fundamental matrices for systems with matrices $A_i = \dot{\mathcal{F}}_i\mathcal{F}_i^{-1}$ in the sectors S_i. We have $A_i = \dot{H}_i H_i^{-1} + H_i A_0 H_i^{-1}$, $A_0 = \dot{\mathcal{F}}_0\mathcal{F}_0^{-1}$. Calculations which use the fact that G_{ij} preserve A_0 show that $A_i = A_j$ at the intersections of sectors. Thus A_j's define one univalent matrix $A(t)$. Because $H_i = I + O(t)$ the matrix $A(t)$ has the same order of pole as A_0, $A(t) = t^{-r}B(t)$ with analytic B.

To prove the existence of such H_j's we use apparatus of the sheaf theory. It turns out that the fact that the Stokes sheaf (and the sheaf $\mathcal{E}$ defined below) is not Abelian is not a serious obstacle to apply the results from the Abelian theory to our purposes.

Firstly we solve the system of equations $G_{ij} = G_j^{-1}G_i$ in the class of smooth (C^∞) matrix-valued functions $G_i = I + O(t)$ in sectors S_i. To do this one introduces the sheaf $\mathcal{E}$ (on S^1) of germs of smooth matrix-functions in sectors, $\mathcal{E}(U) = C^\infty(S_U, GL(n))$. It is a flabby sheaf, admitting partitions of unity, and therefore has trivial higher cohomology groups, $H^i(S^1, \mathcal{E}) = 0$, $i > 0$. In the Abelian case it is given in [36], in the non-Abelian case it is proved in [6].

Assume that we have such G_i's. Because $\bar{\partial}G_{ij} = 0$, we have $\bar{\partial}G_i \cdot G_i^{-1} = \bar{\partial}G_j \cdot G_j^{-1}$. The latter expression defines a univalent in a punctured neighborhood of $t = 0$ smooth function F.

Now, applying a variant of the Poincaré $\bar{\partial}$-lemma, we find a matrix function $G = I + O(t)$ such that $\bar{\partial}G \cdot G^{-1} = F$.

The functions $H_i = G^{-1}G_i$ are holomorphic and satisfy the relation $H_j^{-1}H_i = G_{ij}$. □

Theorem 2.27, together with Theorems 2.17 and 2.19, gives a complete solution of the problem of analytic classification of systems with irregular singularity. The formal normal form is determined in analytic way (using finite number of polynomial transformations). This formal normal form gives the moduli space. A separate problem constitutes the task of computations of the Malgrange–Sibuya moduli, i.e. how to calculate the elements from $H^1(S^1, St)$ from data of the initial analytic system. In the below examples we show how it is done in special cases.

EXAMPLE 2.28. This example comes from the work [88] (see also [89]).

Consider the following function

$$F(t) = \int_{0^+}^{t} s^a \mathrm{e}^{-1/s^k}\varphi(s)\,\mathrm{d}s = \int f(s)\,\mathrm{d}s$$

where φ is a germ of analytic function. We ask when this function is of the local Darboux type

$$F(t) = t^{a+k+1}\mathrm{e}^{-1/t^k}\psi(t), \tag{2.8}$$

with analytic ψ.

To get the answer we introduce the loops σ_j (called also *asymptotic cycles*) as in Fig. 1. The punctured neighborhood of $t = 0$ is divided into sectors of fall and of jump of e^{-1/s^k}

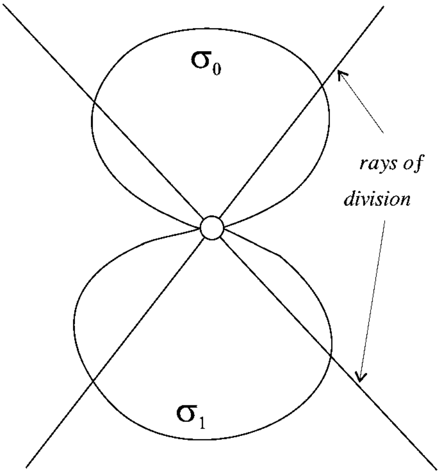

Fig. 1.

as $|t| \to 0$, $\arg t = \text{const}$. Each loop starts and ends at successive sectors of fall (at $t = 0$) and 'surrounds' one sector of jump.

We define the quantities

$$A_j = \int_{\sigma_j} f(s)\,\mathrm{d}s.$$

We have the following property:

The values of $F(t)$ *in neighboring sectors* (*from Fig.* 1) *differ by the constants* A_j. *Therefore the function* F *has the form* (2.8) *iff all* $A_j = 0$.

Consider the linear system

$$t^{k+1}\dot{z} = \begin{pmatrix} -k & t^{k+1}\varphi(t) \\ 0 & at^k \end{pmatrix} z. \tag{2.9}$$

Its general solution is $z_1(t) = D\mathrm{e}^{1/t^k} + C\mathrm{e}^{1/t^k} \int^t f(s)$, $z_2(t) = Ct^a$. Because the singular part of the matrix $A(t)$ is in the diagonal form $A_0(t) = \operatorname{diag}(-kt^{-k-1}, at^{-1})$ then such is also the normalized system.

We choose the system of fundamental solutions of the normalized system in the form $w_1 = \mathrm{e}^{1/t^k}$, $w_2 = t^a$. Therefore $z_1 = w_1 + \eta(t)w_2$, $z_2 = w_2$ where $\eta(t) = t^{-a}\mathrm{e}^{1/t^k}F(t)$.

In different sectors S_j (see Fig. 1) we have different branches of the function F and different branches η_j of η. We have $\eta_{j+1} = \eta_j + A_j t^{-a}\mathrm{e}^{1/t^k}$.

Therefore the normalizing matrices take the form $H_j = \left(\begin{smallmatrix} 1 & \eta_j \\ 0 & 1 \end{smallmatrix}\right)$ and the Stokes cocycle $C_{j,j+1}$ is given by the matrices $\left(\begin{smallmatrix} 1 & A_j \\ 0 & 1 \end{smallmatrix}\right)$.

We have $H^1(S^1, St) \simeq \mathbb{C}^k$ and the Stokes cocycle associated with the system (2.9) is equal to $G_{j,j+1} = \left(\begin{smallmatrix} 1 & A_j t^{-a}\exp(1/t^k) \\ 0 & 1 \end{smallmatrix}\right)$.

EXAMPLE 2.29. (We follow [6] and [37].) Recall the *Bessel equation*

$$t^2\ddot{x} + t\dot{x} + (t^2 - \nu^2)x = 0.$$

We see that the point $t = 0$ is regular (see Definition 2.1 and Theorem 2.7). The point $t = \infty$ turns out irregular.

We introduce the notations $\tau = 1/t$, $u(\tau) = (x(1/\tau), \dot{x}(1/\tau))^\top$ and below by the dot we denote the derivative with respect to τ. Then we get the system $\tau^2\dot{u} = B(\tau)u$, where

$$B = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}\tau + \begin{pmatrix} 0 & 0 \\ -\nu^2 & 0 \end{pmatrix}\tau^2.$$

In order to get the formal normal form we have to transform only the first two terms of $B(\tau)$ to diagonal form. The matrix B_0 has distinct eigenvalues ±i, i.e. we have the non-resonant case. The transformation matrix is chosen in the form $H(t) \sim H_0(I + H_1\tau + \cdots)$, where only the first two terms are important.

We have $H_0 = \left(\begin{smallmatrix} -1 & -\mathrm{i} \\ -\mathrm{i} & -1 \end{smallmatrix}\right)$ and $H_0B_0H_0^{-1} = D_0 = \operatorname{diag}(\mathrm{i}, -\mathrm{i})$. Next $D_1 = H_0(B_1 + [H_1, B_0])H_0^{-1} = H_0B_1H_0^{-1} + [\tilde{H}_1, D_0]$, $\tilde{H}_1 = H_0H_1H_0^{-1}$. The commutator in the latter expression acts onto the non-diagonal entries (because D_0 is diagonal) and, choosing suitable $\tilde{H}_1$, we can obtain D_1 in the diagonal form. Because $H_0B_1H_0^{-1} = \frac{1}{2}\left(\begin{smallmatrix} 1 & * \\ * & 1 \end{smallmatrix}\right)$, then $D_1 = \frac{1}{2}I$. Thus the basis of solutions of the normalized system is $u_{1,2} = \tau^{1/2}\mathrm{e}^{\pm\mathrm{i}/\tau}e_{1,2} = t^{-1/2}\mathrm{e}^{\pm\mathrm{i}t}e_{1,2}$.

There are two rays of division, both in the real axis, and we can take the covering of $\mathbb{C} \setminus 0$ by two sectors with angles $\frac{3\pi}{2}$: S_1 around the real half-line $\{t > 0\}$ and S_2 around $\{t < 0\}$. The intersection $S_1 \cap S_2$ consists of two sectors around $\{\operatorname{Im} t > 0\}$ and $\{\operatorname{Im} t < 0\}$ respectively.

Recall that the Stokes sheaf consists of such matrix functions $G(t)$ that $G \sim I$ and $GDG^{-1} + \tau^2\dot{G}G^{-1} = D$ (preservation of the normalized system). In view of the fact that $2D_1 = I$ this is equivalent to the following condition:

$$\frac{\mathrm{d}}{\mathrm{d}\tau}(\chi^{-1}G\chi) = 0 \quad \text{where } \chi(\tau) = \operatorname{diag}(\mathrm{e}^{-\mathrm{i}/\tau}, \mathrm{e}^{\mathrm{i}/\tau}).$$

Therefore the map $G \to G = \chi^{-1}G\chi$ defines an isomorphism of the sheaf St with some sheaf of subgroups of $\mathrm{GL}(2, \mathbb{C})$. The first condition for the Stokes sheaf $\chi F\chi^{-1} \sim I$ implies that the matrix elements of F fulfill the conditions $F_{11} = F_{22} = 1$, $F_{21}\mathrm{e}^{-2\mathrm{i}/\tau} \sim 0$, $F_{12}\mathrm{e}^{2\mathrm{i}/\tau} \sim 0$. Therefore, depending in which part of the τ-plane we are, the matrix F takes one of the two forms

$$\begin{pmatrix} 1 & f_+ \\ 0 & 1 \end{pmatrix}, \quad \operatorname{Im} t > 0; \qquad \begin{pmatrix} 1 & 0 \\ f_- & 1 \end{pmatrix}, \quad \operatorname{Im} t < 0. \tag{2.10}$$

The parameters $f_\pm$ parameterize the space $H^1(S^1, St)$ and constitute the moduli of analytic classification of equations which are formally equivalent to the Bessel equation.

We calculate the constants f_+, f_- for the very Bessel equation following the book of J. Heading [37]. One uses the basis of solutions of the Bessel equation consisting of the *Bessel functions*

$$J_{\pm\nu}(t) = \sum_{j=0}^{\infty} \frac{(-1)^j (t/2)^{2j\pm\nu}}{j!\Gamma(\pm\nu + j + 1)} = t^{\pm\nu} P_\pm(t^2). \tag{2.11}$$

Note that the function $P_\pm$ are integer. Assume that a solution $AJ_\nu(t) + BJ_{-\nu}(t)$ has the asymptotic expansion $\sim t^{-1/2}\mathrm{e}^{\mathrm{i}t}$ for $\arg t = 0$ and $t \to \infty$. After analytic prolongation of this solution to the rays $\arg t = \pi$ and $\arg t = 2\pi$, with the use of formulas (2.10) and (2.11), we obtain

$$\begin{aligned} &A\mathrm{e}^{\mathrm{i}\pi\nu} J_\nu(t) + B\mathrm{e}^{-\mathrm{i}\pi\nu} J_{-\nu}(t) \sim \mathrm{e}^{-\mathrm{i}\pi/2} t^{-1/2} \mathrm{e}^{-\mathrm{i}t}, \\ &A\mathrm{e}^{2\mathrm{i}\pi\nu} J_\nu(t) + B\mathrm{e}^{-2\mathrm{i}\pi\nu} J_{-\nu}(t) \sim \mathrm{e}^{-\mathrm{i}\pi} t^{-1/2} \mathrm{e}^{\mathrm{i}t} + f_- \mathrm{e}^{-\mathrm{i}\pi} t^{-1/2} \mathrm{e}^{-\mathrm{i}t}, \end{aligned}$$

as $t \to +\infty$. Together with $AJ_\nu(t) + BJ_{-\nu}(t) \sim t^{-1/2}\mathrm{e}^{\mathrm{i}t}$ this gives the value

$$f_- = 2\mathrm{i}\cos(\pi\nu).$$

Analogous calculations give $f_+ = 2\mathrm{i}\cos(\pi\nu)$.

2.3. *Appendix. Proof of the normalization theorems*

Here we prove Theorems 2.13 and 2.22. These proof are conceptually similar, since they are reduced to the contraction principle for a suitable map in a Banach space. We begin with the proof of Theorem 2.22, where we follow the book of W. Wasow [85]. Another proof of Theorem 2.22 uses the Gevrey expansions and multi-summability (see next Subsection 3.6 below) and is given in the paper of B. Braaksma [14].

PROOF OF THEOREM 2.22. Recall that this theorem states that:

there exists a unique matrix function $H(t) = I + O(t)$ analytic in a sector S, not containing two rays of division, which transforms the system $t^r \dot{z} = B(t)z$ to the formal normal form system (2.6).

The essential fact which has to be proved is the following

PROPOSITION. *Let the eigenvalues of $B(0)$ be divided into two groups $\lambda_1, \dots, \lambda_p$ and $\lambda_{p+1}, \dots, \lambda_n$ such that $\lambda_i \neq \lambda_j$ for $i \leqslant p < j$. Then there exists a matrix $H(t)$, holomorphic in S, which transforms the system to an analogous system with the matrix $C(t)$ of the block-diagonal form*

$$\begin{pmatrix} C^{11}(t) & 0 \\ 0 & C^{22}(t) \end{pmatrix}.$$

Moreover, we can assume that the sector S is symmetric with respect to the real positive semi-axis and has the magnitude $< \pi/(r-1)$.

PROOF OF PROPOSITION. If $z = H(t)y$ then y satisfies the equation $t^r H\dot{y} = (BH - t^r \dot{H})y$ and we have

$$HC = BH - t^r \dot{H}.$$

So we assume that $B(0)$ is in the block-diagonal form $B(0) = \operatorname{diag}(B^{11}(0), B^{22}(0))$ and we seek $H(t)$ in the form

$$\begin{pmatrix} I & H^{12}(t) \\ H^{21}(t) & I \end{pmatrix}.$$

In what follows we will deal only with H^{12}. The analysis for H^{21} is quite analogous.

The matrix $X(t) = H^{12}(t)$ satisfies the following non-linear differential equation

$$t^r \dot{X} = B^{11}X - XB^{22} + B^{12} - XB^{21}X$$

where $B^{ij}(t)$ are the corresponding block-matrices.

The latter equation is a particular case of the following non-linear equation

$$t^r \dot{u} = \Lambda u + p(t,u), \quad u \in \mathbb{C}^m, \tag{2.12}$$

where Λ has non-zero eigenvalues Λ_k (equal to $\lambda_i - \lambda_j$ in our case) and the term p is non-linear.

Equation (2.12) is equivalent to the following integral equation

$$u(t) = V(t)D + \int_{t_0}^{t} V(t)V^{-1}(s)s^{-r} p\bigl(s, u(s)\bigr)\,\mathrm{d}s \tag{2.13}$$

where $V(t) = \mathrm{e}^{\Lambda/(1-r)t^{r-1}}$ and U is some constant vector.

In fact, the constant vector D and the limit t_0 of integration are in some way connected one with another. One can replace the integration in (2.13) by the integration along some contour $\Gamma(t)$ in the complex s-plane in such a way that it ends at t. In this case the constant vector can be put equal to zero. Moreover, for each component of Eq. (2.13) we can choose the integration path independently.

The main trick of the proof is to choose the path $\Gamma(t)$ in such a way that the expression $V(t)V^{-1}(s)$ is not too big along the path of integration; then we will be able to apply the principle of contracting maps. In particular, we want that the expressions

$$\exp\bigl[\operatorname{Re}\bigl(\Lambda_k(t^{1-r} - s^{1-r})/(1-r)\bigr)\bigr],$$

associated with the k-th components, are not big.

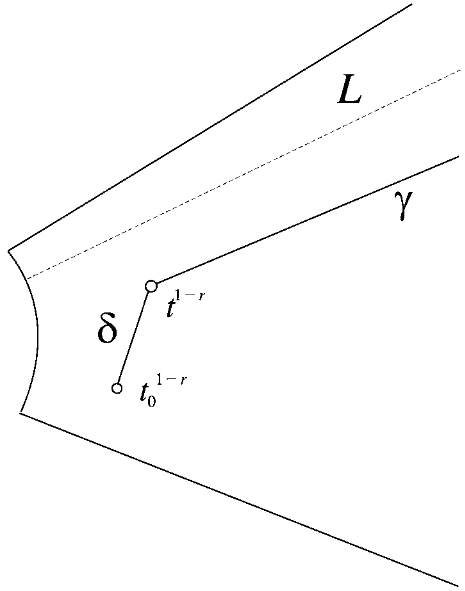

Fig. 2.

We fix for a while the index k and some point $t_0 \in \mathbb{R} \cap S$. We shall consider only such t's that $|t| << t_0$. Moreover it is useful to pass to the chart $\zeta = s^{1-r}$; then the sector S is replaced by a sector with vertex at infinity.

Assume that S does not contain any ray of division corresponding to Λ_k. It means that $\operatorname{Re} \Lambda_k \zeta/(1-r)$ has definite sign in the whole S. Depending on this sign we choose either:

- the straight semi-line γ from $\zeta = \infty$ to $\zeta = t^{1-r}$ with constant $\arg \zeta$, if the sign is positive, or
- the interval δ joining t_0^{1-r} with t^{1-r}, otherwise; (see Fig. 2).

In both cases we have $\operatorname{Re} \Lambda_k (t^{1-r} - \zeta)/(1-r) < 0$.

If S contains a ray of division L (only one by the assumption) then the choice of the path δ remains unchanged but the path γ passes along a straight half-line parallel to L (from infinity to t^{1-r}, see Fig. 2). Here we have $\operatorname{Re} \Lambda_k (t^{1-r} - \zeta)/(1-r) = 0$ along γ.

The further proof uses the standard analytic methods and we describe it only shortly, without detailed estimates.

We solve the fixed point equation

$$u = T(u),$$

where $T(u)$ is the non-linear integral operator $\int V(t) V^{-1}(s) s^{-r} p(s, u(s))\, \mathrm{d}s$ and the integration runs along the paths described above.

In order to apply the method of contracting maps, we must define some Banach space of holomorphic functions u and get an estimate for $\|T(u_1) - T(u_2)\|$ (i.e. the Lipschitz continuity of $p(t, u)$ with respect to u).

The class of u's consists of those which satisfy the estimate $|u(t)| < c|t|^m$ with certain fixed m. This m is defined as the order of $p(t,0) = \mathrm{const}\cdot t^m + \cdots$. One shows that, if u satisfies this estimate, then $|T(u)(t)| < Kc|t|^m$ with a constant K not depending on u (see Lemma 14.2 in [85]).

The Lipschitz estimate $|p(t,u_1) - p(t,u_2)| < \mu|u_1 - u_2|$, with μ arbitrarily small, follows from the fact that p contains only terms of the form $\mathrm{O}(t^m)u^0$, $\mathrm{O}(t)u$ and $\mathrm{O}(|u|^2)$.

Next, one chooses the sequence $u_0 = 0$, $u_1 = T(u_0)$, $u_2 = T(u_1), \ldots$ of successive approximations. One gets $|u_1| < c|t|^m$ and $|u_{n+1} - u_n| < \mu K|u_n - u_{n-1}|$. If $\mu < K^{-1}$ then this series converges to a function holomorphic in some sector S_0 of small radius. □

PROOF OF THEOREM 2.13. Recall that this theorem states that:

for a system $t\dot z = B(t)z$ with Fuchsian and resonant singularity there exists an analytic matrix $H(t)$ which transforms it to a system of the form,

$$t\dot z_i = \lambda_i z_i + \sum_{\lambda_i-\lambda_j\in\mathbb{Z}_+} a_{ij}t^{\lambda_i-\lambda_j}z_j, \quad i = 1,\ldots,n,$$

with constant coefficients a_{ij}.

Note also that the method of the proof of Theorem 2.12 does not work in this situation.

There are finitely many resonant relations $\lambda_i - \lambda_j = k_{ij} \in \mathbb{Z}_+$. Let an integer $m > 0$ be such that $m > \mathrm{Re}(\lambda_i - \lambda_j)$ for all i, j. We can assume that the system takes the form

$$t\dot z = Dz + tB_0(t)z + t^m B_1(t)z,$$

where the matrix D is constant in the Jordan form and $tB_0(t)z$ contains only the resonant terms (like in thesis of the theorem).

We seek the matrix H in the form

$$H(t) = I + t^m G(t)$$

and obtain the equation

$$t\dot G = \bigl([D,G] - mG\bigr) + \bigl(\bigl[tB_0(t), G\bigr] + B_1(t) + t^m B_1(t)G\bigr).$$

It has the same type as Eq. (2.13) but with $r = 1$ and with the eigenvalues of Λ equal $\lambda_i - \lambda_j - m$, which are all non-zero. The fundamental matrix $V(t)$ has the eigenvalues $t^{\lambda_i-\lambda_j-m}$.

The corresponding integral equation is following

$$u(t) = \bigl(T(u)\bigr)(t) = V(t)\int_{t_0}^{t} V(s)^{-1}s^{-1}p\bigl(s,u(s)\bigr)\,\mathrm{d}s,$$

where the initial point t_0 can be chosen equal to 0. Indeed, since $p(s,u(s))$ is bounded and the entries of the matrix $V(s)^{-1}s^{-1}$ vanish at $s = 0$, the above integral is well defined.

It is easy to check that the Lipschitz condition for $p(t,\cdot)$ is satisfied and we can apply the contraction principle. Therefore there exists a unique fixed point for the map T which is an analytic solution to our equation. $\square$

3. Holomorphic vector fields

The previous section was devoted to linear analytic ODEs. In this section we develop the theory of normal forms of non-linear analytic differential equations. These are the equations of the form

$$\dot{x} = V(x), \quad x \in \mathbb{C}^n, \tag{3.1}$$

where $V(x)$ is a holomorphic vector-function, i.e. *holomorphic vector fields*. Here the time t is also complex. Therefore the phase curves become Riemann surfaces and the phase portrait of such a vector field defines a foliation $\mathcal{F}$ into complex phase curves. Such foliations are called *holomorphic foliations*.

The zeroes x_0 of the vector field (3.1) are the *singular points* of the vector field $V(x)$ and of the foliation $\mathcal{F}$. In this (and next) section we study the holomorphic foliations near a singular point, which we assume $x_0 = 0$.

DEFINITION 3.1. Two germs of holomorphic vector fields V and W are called (analytically) *equivalent* if there exists a local analytic diffeomorphism $H:(\mathbb{C}^n,0)\to(\mathbb{C}^n,0)$ transforming V to W, i.e.

$$W = H^*V := (H_*^{-1}V)\circ H.$$

These germs are *formally equivalent* if $H(x)$ is defined by means a formal invertible series and the above equality holds at the level of formal power series.

The germs V and W are called (analytically) *orbitally equivalent* if there exists a local analytic diffeomorphism $H:(\mathbb{C}^n,0)\to(\mathbb{C}^n,0)$ transforming the phase curves of V to phase curves of V. This means that

$$W = F\cdot H^*V$$

where $F \neq 0$ is some analytic function. These germs are *formally orbitally equivalent* if H and F are formal series and the above equality holds at the formal level.

3.1. *Resolution for planar vector fields and the center–focus problem*

This section is not devoted to classification of vector fields with respect to equivalence or orbital equivalence. We present here a result about reduction of a complex singular point of a vector field to a collection of more simple singularities. Moreover we restrict the analysis to the case $n = 2$, i.e. the plane vector fields.

DEFINITION 3.2. A singular point of a germ of planar holomorphic planar vector field is called *elementary* (or *reduced*) iff at least one of its eigenvalues is non-zero.

Thus we can assume that we have

$$\dot{x} = \lambda_1 x + \cdots, \quad \dot{y} = \lambda_2 y + \cdots, \quad \lambda_1 \neq 0.$$

Important invariant of the singular point is the *ratio of eigenvalues*

$$\lambda = \lambda_2 / \lambda_1.$$

If $\lambda \in \mathbb{C} \setminus \mathbb{R}$ then we say that the singular point is a *focus*; if $\lambda > 0$ then it is a *node*; if $\lambda < 0$ then it is a *saddle*; if $\lambda = 0$ then it is *saddle–node*.

The singular point is called *resonant* if λ is a rational number. The resonant node is called *dicritical* if it is formally equivalent to its linear part.

DEFINITION 3.3. The *elementary blowing-up* is the map

$$\pi : (M, E) \to (\mathbb{C}^2, 0),$$

where M is a 2-dimensional complex manifold equal (as a set) to $(\mathbb{C}^2 \setminus 0) \sqcup E$, where $E \simeq \mathbb{C}P^1$ is the set of lines passing through the origin. E is called the *exceptional divisor*. If $(u_1 : u_2)$ are the homogeneous coordinates in $\mathbb{C}P^1$ then the blowing-up map is locally given by the formulas

$$(x, u) \to (x, xu), \quad u = u_2/u_1, \quad (u_1 \neq 0),$$
$$(y, z) \to (yv, y), \quad v = u_1/u_2, \quad (u_2 \neq 0).$$

If $V : (\mathbb{C}^2, 0) \to (\mathbb{C}^2, 0)$ is a germ of holomorphic vector field, then after the elementary blowing-up we obtain usually not a vector field in M but rather a field of directions $\tilde{V}$ near the distinguished divisor E. In the local (x, u)-charts (or (y, v)-charts) in M this field of directions is defined by means of an analytic vector field.

Let $V : (\mathbb{C}^2, 0) \to (\mathbb{C}^2, 0)$ be a germ of holomorphic vector field. We say that it admits a *good resolution* if after a *finite* number of elementary blowing-ups we obtain a field of directions in a 2-dimensional complex manifold with only elementary and non-dicritical singular points.

EXAMPLE 3.4. *A general homogeneous vector field of degree n*

$$\dot{x} = P_n(x, y), \qquad \dot{y} = Q_n(x, y)$$

has $n + 1$ *invariant lines*.

Indeed, in the blowing-up coordinates $x, u = y/x$ we get the system $\dot{x} = x^n P_n(1, u)$, $\dot{u} = x^{n-1}[Q_n(1, u) - u P_n(1, u)] = x^{n-1} H_{n-1}(u)$, where the polynomial $H_{n+1}(u)$ in the square brackets is (generally) non-zero. In order to obtain a field of directions one has

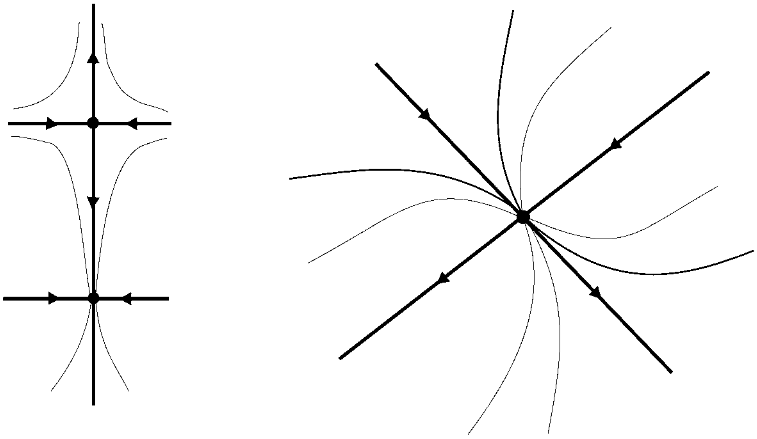

Fig. 3.

to divide the latter system by x^{n-1}. The zeroes u_i of $H_{n+1}(u)$ define the invariant lines $y = u_i x$, see Fig. 3.

If the zeroes u_i are isolated then we can perturb this vector field by adding terms of degree $> n$ and the above blowing-up gives the resolution of the perturbed vector field; the singular points $(u_i, 0)$ remain elementary.

If $P_n = xR_{n-1}$, $Q_n = yR_{n-1}$ then $H_{n+1} \equiv 0$ and the foliation in the (x,u)-coordinates is the flow-box foliation. If additionally we consider perturbation, with terms of higher degree of general type, then in the resolution we must divide the blown-up vector field by x^n. The blowing-up defines the resolution of the singularity but the exceptional divisor $x = 0$ is not invariant for the corresponding foliation. In such a case we say that the divisor E is *dicritical*.

EXAMPLE 3.5. Consider the *Bogdanov–Takens singularity*

$$\dot{x} = 2y, \quad \dot{y} = ax^2 + bxy + cy^2 + \cdots,$$

where we assume that $a \neq 0$ (and we can put $a = 3$). This system can be treated as a small perturbation of the Hamiltonian system X_H with the Hamilton function $H = y^2 - x^3$ with the cusp singularity. Indeed, in the quasi-homogeneous filtration with the exponents $d(x) = 2$, $d(y) = 3$, the Hamiltonian part has degree 1 and the remaining terms have greater degrees.

The blowing-up of the cusp curve is presented at Fig. 4. It is easy to see that the same elementary blowing-up maps can be applied to the Bogdanov–Takens singularity. The resolved field of directions has the same singularities as X_H which are also hyperbolic saddles. The curve Γ is an invariant curve of the vector field (separatrix) and has the cusp singularity. We shall return to this singularity in the next section.

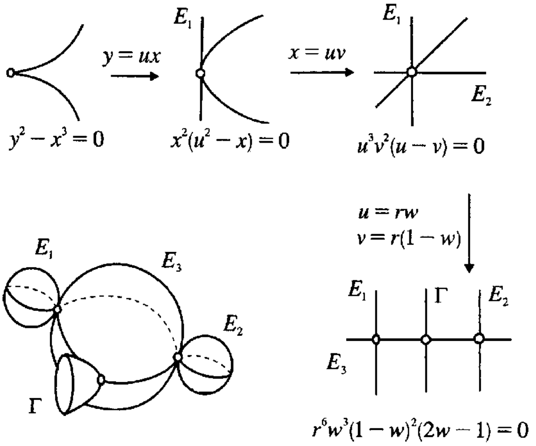

Fig. 4.

The following theorem is principal in this section. It was firstly formulated by I. Bendixson under the assumption that the vector field is real and analytic. F. Dumortier also considered the real case with only elementary singularities at the end. Moreover, he assumed that the initial vector field is only smooth. The assumption that the singular point is isolated is replaced by the following *Łojasiewicz condition* $|V(x)| > C|x|^{\alpha}$. Our version of the desingularization theorem was firstly formulated by A. Seidenberg. However its final proof, which is the just proof, was given by A. van den Essen.

THEOREM 3.6. (See [10,70,27,32].) *Any germ of analytic planar vector field with isolated singularity admits a good resolution.*

REMARK 3.7. There exists an analogous theorem (about desingularization) for germs of holomorphic foliations of codimension 1 in $(\mathbb{C}^3, 0)$ (see [22]). But no analogous result about the codimension 1 foliations is known in dimensions >3. Also there is no desingularization theorem for holomorphic vector fields in dimensions >2.

PROOF OF THEOREM 3.6. (We follow the article of J.-F. Mattei and R. Moussu [56] and [89].)

1. If we have a $p : q$ resonant node $\dot{x} = px + \cdots$, $\dot{y} = qy + \cdots$, $p < q$, then the resolved vector field has two singular points in the divisor $E = \{(u_1 : u_2)\}$: the $p : (q - p)$ resonant node $(1 : 0)$ (i.e. $\dot{x} \approx px$, $\dot{u} \approx (q - p)u$) and $p : (p - q)$ resonant saddle $(0 : 1)$. If the node $x = y = 0$ is dicritical then the node $(1 : 0)$ is also dicritical.

Repeating this several times, we arrive to a $1 : 1$ resonant node which after elementary blowing-up is transformed to the flow-box (see Example 3.4).

2. We work with the vector fields $V = b(x, y)\partial_x - a(x, y)\partial_y$ and with the equivalent to them 1-forms

$$\omega = a\,\mathrm{d}x + b\,\mathrm{d}y.$$

We recall the definition of *index* of the vector field (or of the 1-form) $i_0(V) = i_0(\omega) = i(a, b; 0)$. Let $b(x, y) = 0$ be an irreducible (analytic) curve passing through the origin. It can be locally parametrized by an analytic map $(\mathbb{C}, 0) \ni t \to \gamma(t) \in (\mathbb{C}^2, 0)$ such that $b \circ \gamma \equiv 0$. There is the so called *primitive parametrization* such that any other parametrization of the same curve is induced from the primitive parametrization by a change of parameters. (Example: the primitive parametrization of the cusp $y^2 = x^3$ is $x = t^2$, $y = t^3$.) Then we have $a \circ \gamma(t) = \alpha t^d + \cdots$, $\alpha \neq 0$. We get $i(a, b; 0) = d$. If the function b has the representation $b = b_1^{l_1} \cdots b_r^{l_r}$ with irreducible b_j's then $i(a, b; 0) = \sum l_j \cdot i(a, b_j; 0)$.

Note that $i_0(V) = 1$ iff 0 is a non-degenerate elementary singular point, i.e. not a saddle-node.

The *rank* of the vector field (or of the 1-form) $\nu(V) = \nu(\omega) = \nu_0(\omega)$ equals to the order of the first non-zero term in the Taylor expansion of V at 0. Analogously one defines the rank of a function.

3. LEMMA. *Let $\pi : (x, u) \to (x, xu)$ be the blowing-up map with the exceptional divisor $E = \pi^{-1}(0)$. We define the functions $\tilde{a}, \tilde{b}$ by the formulas*

$$a \circ \pi = x^{\nu(a)} \tilde{a}, \qquad b \circ \pi = x^{\nu(b)} \tilde{b}.$$

Then we have

$$i(a, b; 0) = \nu(a)\nu(b) + \sum_{z \in E} i(\tilde{a}, \tilde{b}; z).$$

PROOF. When the polynomial $\tilde{b}(0, u)$ has only simple zeroes $z \in E$ (there is $\nu(b)$ of them) then each such zero gives the contribution $\nu(a) + i(\tilde{a}, \tilde{b}; z)$ to the index $i(a, b; 0)$. The general case is a consequence of the additivity of the index; for a family V_ε of vector fields with singular points $x_i(\varepsilon)$, $i = 1, \ldots, k$, degenerating to 0 as $\varepsilon \to 0$ we have $i_0 V_0 = \sum i_{x_j}(V_\varepsilon)$. □

4. PROPOSITION. *There exists a sequence of elementary blowing-ups such that at the end we obtain only singularities with rank $\leqslant 1$.*

PROOF. Let $\omega_\nu = a_\nu\, \mathrm{d}x + b_\nu\, \mathrm{d}y$ be the homogeneous part of ω of order $\nu = \nu(\omega) = \min(\nu(a), \nu(b))$. We put

$$P_{\nu+1} = x a_\nu + y b_\nu.$$

Then we have

$$\begin{aligned}
\pi^* \omega &= a(x, ux)\, \mathrm{d}x + b(x, ux)\, \mathrm{d}(ux) \\
&= (a + ub)\, \mathrm{d}x + xb\, \mathrm{d}u \\
&= x^\nu \bigl\{ \bigl[P_{\nu+1}(1, u) + \cdots \bigr] \mathrm{d}x + x \bigl[b_\nu(1, u) + \cdots \bigr] \mathrm{d}u \bigr\}.
\end{aligned}$$

Here the case with $P_{\nu+1} \equiv 0$ is dicritical.

For any $z \in E$ we define the germ $\tilde{\omega} = \tilde{\omega}_z$ as the germ of $\pi^*\omega$ at z, divided by the greatest common multiplier of the germs its components. Thus if $\pi^*\omega = a_1\,\mathrm{d}x + b_1\,\mathrm{d}u$, then $\tilde{\omega} = \pi^*\omega/\gcd(a_1, b_1)$. The Pfaff equation $\tilde{\omega} = 0$ defines the blown-up foliation near z.

Proposition 4 follows from the following result. □

5. LEMMA. *If $\nu > 1$ then for any $z \in E$ we have*

$$i_z(\tilde{\omega}) < i_0(\omega).$$

PROOF. Consider firstly the dicritical case, i.e. $P_{\nu+1} \equiv 0$. We shall show the identity

$$i_0(\omega) = \nu^2 + \nu - 1 + \sum i_z(\tilde{\omega}).$$

We can choose a local system of coordinates $(x, y) \to (x + \cdots, y + \cdots)$ such that the following conditions hold:

(i) $P(x, y) = xa + yb$ has rank exactly $\nu + 2$;
(ii) $b(0, y) = y^{\nu+1}$ (then $P(0, y) = y^{\nu+2}$).

We have

$$i(P, b; 0) = i(x, b; 0) + i(a, b; 0)$$

where

$$i(P, b; 0) = \nu(\nu + 2) + \sum i(\tilde{P}, \tilde{b}; z)$$

(by Lemma 3) and $i(x, b; 0) = \nu + 1$ (by (ii)). Now one must only notice that $\tilde{\omega} = \tilde{P}\,\mathrm{d}x + \tilde{b}\,\mathrm{d}u$ and thus $i(\tilde{P}, \tilde{b}; z) = i_z(\tilde{\omega})$.

Consider now the non-dicritical case $P_{\nu+1} \not\equiv 0$. We shall prove that

$$i_0(\omega) = \nu^2 - \nu - 1 + \sum i_z(\tilde{\omega}).$$

We have (by Lemma 3)

$$i(a, b; 0) = \nu^2 + \sum i(\tilde{a}, \tilde{b}; z). \tag{3.2}$$

Next

$$i_z(\tilde{\omega}) = i(\tilde{a} + u\tilde{b}, x\tilde{b}; z) = i(\tilde{a} + u\tilde{b}, x; z) + i(\tilde{a}, \tilde{b}; z)$$

where $i(\tilde{a} + u\tilde{b}, x; z)$ is the multiplicity of z as zero of the polynomial $P_{\nu+1}$; the sum of these multiplicities is $\nu + 1$.

Summing up the latter equality over z's and taking into account (3.2) we get the result. □

6. Let $\nu = 1$. The only case with non-elementary singular point of rank one is the case with nilpotent linear part $\dot{x} = y + \cdots$, $\dot{y} = \cdots$. The corresponding 1-form is following

$$\omega = \left[y + A_1(x, y)\right] \mathrm{d}y + B_1(x, y)\, \mathrm{d}x,$$

with $\nu(A_1), \nu(B_1) \geqslant 2$.

After blowing-up in the x-direction, i.e. with $y = xu$, we get $\tilde{\omega} = x(u + xA_2)\, \mathrm{d}u + (u^2 + xB_2)\, \mathrm{d}x$ where A_2, B_2 are analytic functions (without restrictions onto ranks). The latter form can be included into the following series of 1-forms

$$\eta = x(y + xA)\, \mathrm{d}y + (ny^2 + xB)\, \mathrm{d}x \tag{3.3}$$

where n is a natural number. In what follows we deal with (3.3).

Note also that $\nu(\eta) = 2$.

7. Let $B(0) = b_0 \neq 0$. Here we blow-up η in the y-direction by putting $x = vy$. We obtain

$$\tilde{\eta} = v\left[(n + 1)y + b_0 v + A'\right] \mathrm{d}y + y[ny + b_0 v + B']\, \mathrm{d}v.$$

This form has good quadratic part. Note that the polynomial

$$P_3(\tilde{\eta}) = vy\left[(2n + 1)y + 2b_0 v\right]$$

has distinct factors. After the next blowing up we obtain three elementary singular points (see Example 3.4).

8. Let $B(0) = 0$. From (3.3) we get

$$P_3(\eta) = x\left[(n + 1)y^2 + \alpha xy + \beta y^2\right] = (n + 1)x(y - c_1 x)(y - c_2 x).$$

If $c_1 \neq c_2$ then the next blowing-up solves the problem (like in the point 7).

Let $c_1 = c_2$. Eventually applying the change $y \to y - cx$ we can assume that $c_1 = c_2 = 0$, i.e. $P_3(\eta) = (n + 1)xy^2$. The singular point $(0 : 1) \in E$, corresponding to the line $x = 0$ in $P_3 = 0$, is elementary; the point $(1 : 0)$ is non-elementary. Then calculations of the blowing up with $y = ux$ give

$$\tilde{\eta} = x(u + A')\, \mathrm{d}u + \left[(n + 1)u^2 + xB'\right] \mathrm{d}x$$

where $A' = A(x, ux)$ and $B' = B(x, ux)/x + uA(x, ux)$.

If $A(0) \neq 0$ then the point $x = u = 0$ is elementary.

9. Let $A(0) = 0$. Then $A' = xA''$ and $\tilde{\eta}$ has the same form as η in (3.3) but with n replaced by $n + 1$. So we can repeat the analysis from the points 7 and 8. We have two possibilities: either after finitely many steps we obtain elementary singular point or infinitely many times we obtain the form (3.3).

However the second possibility contradicts Proposition 4, because we would get infinitely many times $\nu > 1$. This contradiction proves Theorem 3.6. □

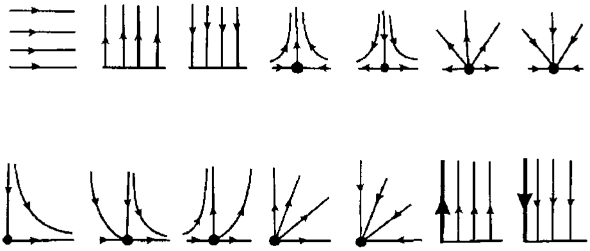

Fig. 5.

Theorem 3.6 has important consequences in the complex domain and in the real domain. Below we present its application in the study of phase portraits of real analytic vector field about a singular point.

Theorem 3.6 implies that after blowing-ups the phase portrait near the distinguished divisors can be composed from the finite collection of standard portraits (presented at Fig. 5).

COROLLARY 3.8. *The resolution of singular point of a real vector field allows to determine its topological type modulo solution of the center–focus problem. If there is a characteristic trajectory* (*see Definition* 3.9) *of the resolved field* (*tending to a point in the distinguished divisors*) *then the topological type of the vector field is completely determined*; *if there is no characteristic trajectory then the topological type is determined by the stability type of the singularity.*

Therefore we arrive to the center–focus problem for germs of analytic vector fields.

DEFINITION 3.9. The *characteristic trajectory* of a real planar vector field V at the singular point $x = 0$ is a phase curve which approaches the singularity with definite limit direction. It means that after resolution some local phase portrait different from the first and eighth portraits in Fig. 5 appears.

If there is no characteristic trajectories then the singular point is called *monodromic*.

The *center–focus problem* is the problem of describing conditions for stability or unstability of a monodromic singular point for analytic vector field.

V. Arnold [3] formulated this problem as follows. The space J^k of k–jets j^kV at $x = 0$ of germs $V : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)$ of analytic vector fields is divided into three subspaces J_s^k, J_u^k and J_n^k. Here the jets j^kV from J_s^k (respectively from J_u^k) are such that any germ W with $j^kW = j^kV$ has 0 as an asymptotically stable point (respectively unstable point). The subspace J_n^k consists of 'neutral' jets. Arnold asked whether the sets $J_{s,u,n}^k$ are semi-algebraic, or semi-analytic, and conjectured that the codimension of J_n^k grows to infinity with k.

In practice one divides the center–focus problem into two problems. Firstly one asks whether the singular point is monodromic; then one can define the Poincaré return map from an arc ending at the singularity to itself. Next one calculates the asymptotic expansion of the Poincaré map.

Theorem 3.6 implies that the monodromicity problem is algebraically solvable, i.e. that the division of the space J^k into 'stably' monodromic, non-monodromic and neutral jets is defined by algebraic equations and inequalities onto the coefficients of the Taylor expansion of V.

Therefore there appears the problem of calculating the leading term in the asymptotic expansion of the Poincaré map for germs from a given class. Such class may consists, for example, of germs with a fixed resolution of the singularity.

The first case with elementary singular point, i.e. with imaginary eigenvalues, was solved by H. Poincaré and A. Lyapunov.

THEOREM 3.10. (See [67,51].) *The problem of distinguishing between center and focus for germs of the form*

$$\dot{x} = -y + \cdots, \qquad \dot{y} = x + \cdots$$

is algebraically solvable. More precisely, the Poincaré map $\mathcal{P}$: $\{x = r \geqslant 0, y = 0\} \to \{x \geqslant 0, y = 0\}$ *has the expansion*

$$\mathcal{P}(r) = r + g_3 r^3(1 + \cdots) + g_5 r^5(1 + \cdots) + \cdots$$

where the Poincaré–Lyapunov focus quantities g_{2j+1} *are polynomials with respect to* (*finite number*) *of coefficients of the Taylor expansion of the vector field.*

Moreover, if all $g_j = 0$ *for a given germ* V *then there exists a local analytic first integral*

$$F = x^2 + y^2 + \cdots$$

and the singular point $x = y = 0$ *is a center for* V.

PROOF. It is useful to pass to the complex variables $z = x + \mathrm{i}y$, $\bar{z} = x - \mathrm{i}y$. Then we have

$$\dot{z} = \mathrm{i}z + \sum a_{kl} z^k \bar{z}^l.$$

We look for a Lyapunov function (in the stable or unstable case) or for a first integral $F = z\bar{z} + \sum f_{kl} z^k \bar{z}^l$. It should satisfy the equation

$$\dot{F} = \frac{1}{\pi}\left(g_3|z|^4 + g_5|z|^6 + \cdots\right),$$

where the coefficients f_{kl} and $\frac{1}{\pi} g_j$ are defined recursively. We get a system of equations $\sqrt{-1}\,(k-l) f_{kl} = -(a_{k,l-1} + \bar{a}_{k-1,l}) +$ (terms depending on previous f_{ij}'s). We see that we can calculate f_{kl} always when $k \neq l$, when $k = l$ we find the obstacle which equals $\frac{1}{\pi} g_k$.

To relate the expansion of $\dot{F}$ with the expansion of the Poincaré map we parametrize the section by $F = r^2 + \cdots$. Then $\mathcal{P}(r) - r = \int_0^T \dot{r}\, \mathrm{d}t \approx \frac{1}{2r} \int_0^{2\pi} \dot{F}\, \mathrm{d}t \approx \frac{1}{2r} \cdot 2\pi \cdot \frac{g_{2j-1}}{\pi} r^{2j}$, where $T \approx 2\pi$ is the return time to the section and g_{2j-1} is the first non-zero coefficients in $\dot{F}$.

The proof of the analyticity of the first integral in the center case can be obtained by direct estimations of the coefficients (like in [67] and [51]). There exists a geometrical proof, due to R. Moussu [63], which uses the monodromy transformation Δ_γ associated with a loop γ in one of the separatrices $\Gamma_+ = \{x + \mathrm{i}y + \cdots = 0\} \subset (\mathbb{C}^2, 0)$ (see Theorem 3.20 and Definition 3.42 below). Δ_γ is a holomorphic map from a small disc $D \simeq (\mathbb{C}, 0)$ transversal to Γ_+ at the base point of the loop γ (which surrounds the point $x = y = 0$ in Γ_+) to itself. Due to the vanishing of the Poincaré–Lyapunov quantities it is an identity map. So, we can define the first integral F; firstly on $(\mathbb{C}^2, 0)\backslash$separatrices by the intersection of the leaves of the complex foliation $\mathcal{F}$ with the disc D (parametrized by $F|_D : D \to (\mathbb{C}, 0)$), next on the separatrices by putting $F = 0$. This function F turns out holomorphic in $(\mathbb{C}^2, 0)$. For more details we refer the reader to [63]. □

The next is the case of nilpotent singular points:

$$\dot{x} = y + \cdots, \qquad \dot{y} = \cdots.$$

Here we have so-called Takens–Bogdanov normal form

$$\dot{x} = y + a(x), \qquad \dot{y} = \varepsilon x^{s-1}, \tag{3.4}$$

where $a(x) = a_r x^r + a_{r+1} x^{r+1} + \cdots$, $a_r \neq 0$ and $\varepsilon = \pm 1$ (see Theorem 4.2 and Proposition 4.5 in Section 4). The coefficients a_j in the expansion of $a(x)$ are algebraic functions of the coefficients in the Taylor expansion of the vector field V and this normal form is analytic. The following result belongs to A. Sadovski and R. Moussu.

THEOREM 3.11. (See [68,62].) *The singularity $x = y = 0$ of a vector field V with the Takens–Bogdanov form* (3.4) *is monodromic if and only if*: *s is even, $\varepsilon = -1$ and either $r > \frac{s}{2}$ or $r = \frac{s}{2} = 2\tilde{r}$ is even and $ra_r^2 < 4$.*

In this case the singular point is a center iff all the coefficients a_{2j} with odd indices vanish. If a_{2j+1} is the first non-zero odd coefficient, then the singular point is stable (*respectively unstable*) *if $a_{2j+1} < 0$* (*respectively $a_{2j+1} > 0$*).

PROOF. The conditions: s even, $\varepsilon = -1$, $s \leqslant 2r$ and $s = 2r$ but r even follow from qualitative analysis of the phase portrait of the system (3.4).

If $s = 2m$ is even then the leading part of this system, with respect to the quasi-homogeneous gradation such that degree of y equals m times degree of x, is

$$\dot{x} = y + a_{2\tilde{m}} x^{2\tilde{m}}, \qquad \dot{y} = -x^{2m-1} \tag{3.5}$$

(compare Section 4.1). Here the term $a_{2\tilde{m}} x^{2\tilde{m}} = a_m x^m$, $m = 2\tilde{m}$, vanishes when $s < 2r$ and when $s = 2r$ but r is odd. This system is invariant with respect to the reflection $x \to -x$ and reversion of time; we say that the system is *time–reversible*. Hence system (3.4) is monodromic iff system (3.5) has center at the origin. Moreover, the change $z = x^m$ and division by x^{m-1} gives a linear system with eigenvalues $\lambda_{1,2} = \frac{1}{2}(ma_m \pm \sqrt{m^2 a_m^2 - 4m})$.

In the case with real eigenvalues the linear system has an invariant line (eigenspace) which gives a characteristic trajectory for system (3.4). Therefore $m^2a_m^2 - 4m < 0$.

To prove the second statement we assume that a_{2j+1} is the first non-zero odd coefficient. Then the initial part

$$\dot{x} = y + a_{2\tilde{m}}x^{2\tilde{m}} + \cdots + a_{2j}x^{2j}, \qquad \dot{y} = -x^{2m-1}$$

of the (3.4) is time-reversible and hence with center at the origin. It has first integral $F(x, y)$, which can be not analytic at the origin, but its first approximation is a first integral $F_0(x, y)$ of the quasi-homogeneous vector field (3.5). F_0 is of the form $(y - \mu_1x^m)^{\lambda_1}(y - \mu_2x^m)^{\lambda_2}$. The term $a_{2j+1}x^{2j+1}\partial_x$ is the first perturbation of the latter system and we can calculate the increments of the first integral F along trajectories of the perturbed system. Near the origin it is approximately the increment of F_0 and can be expressed in terms of the Melnikov type integral $\int_{F_0=h} \frac{\partial F_0}{\partial x}x^{2j+1}\,\mathrm{d}t$, where $\mathrm{d}t = -\mathrm{d}y/x^{2m+1}$.

The result is that the latter integral is positive. □

The following example demonstrates that in the case of more degenerate non-elementary monodromic singular point the center focus problem is not analytically solvable. (Another example of similar type was given by Y. Il'yashenko in [41].)

EXAMPLE 3.12. Consider the following family of vector fields

$$\begin{aligned}\dot{x} &= -y\big[(2\mu + 1)x^2 + y^2\big] + x^2\big[\lambda_1x^2 + \lambda_2(x^2 + y^2)\big],\\ \dot{y} &= x\big[x^2 + (1 - 2\mu)y^2\big] + xy\big[\lambda_1x^2 + \lambda_2(x^2 + y^2)\big].\end{aligned}$$

Each vector field from this family is of the type

$$V = V_d + f \cdot E,$$

where V_d is a homogeneous vector field of degree d, $E = x\partial_x + y\partial_y$ is the *Euler vector field* and $f(x, y)$ is a homogeneous polynomial of degree $d + k$. It has first integral of the so called *Darboux–Schwarz–Christoffel type*

$$H = x^{-k}M(u) + k\int^u M(v)P(v)B(v)^{-1}\,\mathrm{d}v, \quad u = y/x,$$

where $M(u) = \mathrm{e}^{g(u)}\prod(u - u_j)^{\alpha_j}$ is of generalized Darboux type and $B(u) = \prod(u - u_j)^{m_j}$ and $P(u)$ are polynomials. Indeed, in the variables x, u we get the Bernoulli equation $\frac{\mathrm{d}x}{\mathrm{d}u} = \frac{A(u)}{B(u)}x + \frac{P(u)}{B(u)}x^{k+1}$, $P(u) = f(1, u)$, with the first integral as above, where $M = \exp\int A/B$. The center conditions mean that the function $H(x, y)$ is single–valued in $\mathbb{R}^2\setminus 0$. This implies that the homogeneous function $x^{-k}M(y/x)$ is single valued and that $\int_{-\infty}^{\infty} M(v)P(v)B(v)^{-1}\,\mathrm{d}v = 0$.

In our case the first integral equals $H = (x^2 + y^2)^{-1/2} e^{\mu x^2/(x^2+y^2)} + F(y/x)$, where

$$F(u) = \int_{-\infty}^{u} e^{\mu/(v^2+1)} (v^2 + 1)^{-3/2} \bigl[\lambda_1 + \lambda_2 (v^2 + 1)\bigr] \, dv.$$

The center condition means that $F(-\infty) = F(\infty) = 0$. It can be rewritten in the form

$$\lambda_1 \Psi'(\mu) + \lambda_2 \Psi(\mu) = 0,$$

where

$$\begin{aligned}\Psi(\mu) &= \int_{-\infty}^{\infty} \frac{e^{\mu/(v^2+1)}}{\sqrt{v^2+1}} \, dv = \frac{2}{\sqrt{\mu}} e^{\mu} \int_0^{\sqrt{\mu}} e^{-z^2} \, dz \\ &= \frac{2}{\sqrt{\mu}} e^{\mu} \operatorname{Erf}(\sqrt{\mu}) = 2 e^{\mu} \Phi(1/2, 3/2; -\mu)\end{aligned}$$

where Erf is the probability integral and $\Phi(a, c; x) = 1 + \frac{a}{c}\frac{x}{1!} + \frac{a(a+1)}{c(c+1)}\frac{x^2}{2!} + \cdots$ is the confluent hypergeometric function. By the Kummer identity $\Phi(a, c; x) = e^x \Phi(c - a, c; -x)$ (see [9]) we have $\Psi(\mu) = \Phi(1, 3/2; \mu)$.

The function Ψ has the following properties (see [9]):

- $\Psi(\mu)$ is an entire function,
- $\Psi(\mu) \sim \Gamma(\frac{3}{2}) e^{\mu} \mu^{-1/2}$ as $\operatorname{Re} \mu \to \infty$,
- $\Psi(\mu) \sim -\frac{1}{2\mu}$ as $\operatorname{Re} \mu \to -\infty$.

Therefore Ψ is not of the form polynomial× exp(polynomial). The same holds for the function $\psi(\mu) = \lambda_1 \Psi'(\mu) + \lambda_2 \Psi(\mu)$. Therefore the function $\psi(\mu)$ has infinitely many zeroes in $\mathbb{C}$ and hence the set $\{(\lambda_1, \lambda_2, \mu)\colon \lambda_1 \Psi'(\mu) + \lambda_2 \Psi(\mu) = 0\}$ is not semi-algebraic.

The above shows that the problem of center is not algebraically solvable.

On the other hand Y. Il'yashenko proved the following almost algebraic solvability of the center–focus problem.

THEOREM 3.13. (See [41].) *Consider a class of germs of vector fields of the form*

$$\dot{x} = P_n + \cdots, \qquad \dot{y} = Q_n + \cdots \tag{3.6}$$

where $P_n(x, y)$ *and* $Q_n(x, y)$ *are fixed homogeneous polynomials such that the polynomial*

$$R_{n+1}(x, y) = x Q_n - y P_n \tag{3.7}$$

is non-zero in $\mathbb{R}^2 \setminus 0$. *Then the problem of stability of the singularity* 0 *is algebraically solvable with respect to the coefficients of higher order terms in* (3.6).

PROOF. The phase curves of the system (3.6) in the polar coordinates r, φ satisfy the equation

$$\frac{\mathrm{d}r}{\mathrm{d}\varphi} = \frac{A_{n+1}(\varphi)r + A_{n+2}(\varphi)r^2 + \cdots}{B_{n+1}(\varphi) + B_{n+2}(\varphi)r + \cdots}$$

where

$$A_{n+1}(\varphi) = S_{n+1}(\cos\varphi, \sin\varphi),\ A_{n+2}(\varphi), \dots ,$$
$$B_{n+1}(\varphi) = R_{n+1}(\cos\varphi, \sin\varphi),\ B_{n+2}(\varphi), \dots, S_{n+1}(x, y) = xP_n + yQ_n, \dots ,$$

are trigonometric polynomials. Moreover, $B_{n+1}(\varphi) \neq 0$.

Therefore, the solutions $r = r(\varphi; r_0)$ which satisfy the initial condition $r(0; r_0)$ can be expanded into power series $\sum a_j(\varphi)r_0^j$, where the coefficients are calculated recursively. Hence the Poincaré map is also expanded into power series $\mathcal{P}(r_0) = c_1 r_0 + c_2 r_0^2 + \cdots$. The first coefficient equals

$$c_1 = \exp\left(\int_0^{2\pi} \frac{A_{n+1}(\psi)}{B_{n+1}(\psi)}\,\mathrm{d}\psi\right) = \exp\left(2\int_{-\infty}^{\infty} \frac{P_n(1,u)}{R_{n+1}(1,u)}\,\mathrm{d}u\right) \tag{3.8}$$

and the sequel coefficients depend polynomially on the coefficients in the polynomials $A_{n+2}, B_{n+2}, A_{n+3}, \dots$. □

The quantity

$$g_1 = \ln c_1$$

is called the *first focus quantity*.

In formula (3.8) for the first focus quantity only one blowing-up of the singularity was used. N. Medvedeva generalized this formula to a more general case.

THEOREM 3.14. (See [57].) *Assume that we have a germ of the form* (3.6) *with monodromic singularity and such that the resolution of this singularity involves two blowing-ups* (*so the polynomial* $R_{n+1}(x, y)$ *has a zero*). *Then the first focus value is defined, i.e.* $c_1 = \mathcal{P}'(0) \neq 0$, *and equals*

$$g_1 = 2 \cdot \left(\text{V.P.} \int_{-\infty}^{\infty} \frac{P_n(1,u)}{R_{n+1}(1,u)}\,\mathrm{d}u\right),$$

where V.P. denotes the principal value of an integral from a rational function.

The proof of this theorem relies on decomposing the Poincaré map into composition of correspondence maps (defined by phase curves of the resolved foliation) near the saddle point (which is the intersection point of two exceptional divisors) and near the remaining parts of the divisor. We do not present this proof.

We finish this section by presenting (without proof) the following recent result of N. Medvedeva which solves the problem of analytical solvability of the Arnold's problem about center and focus. She restricts the problem to a fixed *class of germs with monodromic singular point*; such class consists of germs with fixed scheme of resolution of the singularity.

THEOREM 3.15. (See [58,59].) *The center–focus problem is analytically solvable in any class of germs with monodromic singularity. More precisely, the Poincaré map admits asymptotic expansion*

$$\mathcal{P}(\rho) = c_1\rho + \sum P_k(\ln\rho)\rho^{\nu_k},$$

where $c_1 > 0$, *the exponents* ν_j *grow to infinity and the coefficients* $P_k(\ln\rho)$ *are polynomials whose coefficients depend analytically on the coefficients of the jets* $j^{s_k}V$ *and* $s_k \to \infty$ *with* k.

3.2. *Poincaré–Dulac normal form*

Consider a germ of holomorphic vector field in $(\mathbb{C}^n, 0)$ of the form

$$\dot{x} = V(x) = Ax + \cdots \tag{3.9}$$

where A is the linearization matrix at the singular point $x = 0$. Let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of the matrix A.

DEFINITION 3.16. We say that the eigenvalues satisfy the *resonant relation of the type* $(i; k)$ if

$$\lambda_i = \lambda_1 k_1 + \cdots + \lambda_n k_n$$

where $k = (k_1, \dots, k_n)$ and k_j are non-negative integers.

We say that the germ (3.9) is of the *Poincaré type* if the convex hull of the set $\{\lambda_1, \dots, \lambda_n\}$ in the complex plane does not contain the origin.

The following result is known as the Poincaré–Dulac normal form.

THEOREM 3.17. (See [4,67,26].) *There exists a change* $x \to y = G(x)$ *given by formal power series which transforms the system* (3.9) *to the system*

$$\dot{y}_i = \lambda_i y_i + \sum_{(i;k)\ \text{resonant}} c_{i;k} y^k, \quad i = 1, \dots, n.$$

PROOF. We apply a series of changes of the type $x \to x' = x + \phi(x)$, where $\phi = (\phi_1, \dots, \phi_n)$ is homogeneous transformation of degree m,

$$\phi_i(x) = \sum_{|k|=m} b_{i,k} x^k.$$

The inverse map has the form $x' \to x = x' - \phi(x') + \cdots$. We strive to cancel all possible terms in the vector field of homogeneous degree m.

We have $\dot{x}_i' = (\text{old part of degree} < m) + (\text{old part of degree } m) + (L_A\phi)_i(x') + \cdots$ where

$$(L_A\phi)_i = \partial\phi_i(x)/\partial x \cdot Ax' - (A\phi)_i$$

is called the *homological operator*.

If the matrix A is diagonal then L is also diagonal:

$$L_A(x^k e_i) = \Bigl(\sum k_j\lambda_j - \lambda_i\Bigr)(x^k e_i)$$

where e_i form the standard basis in $\mathbb{C}^n$. Because the eigenvalues of L_A vanish only at the resonant terms all the non-resonant terms in the vector field of degree m can be canceled in this way.

If A is upper-triangular then, taking the suitable ordering of the basis $x^k e_i$, we get the triangular form of the operator L_A

$$L_A(x^k e_i) = \Lambda_{i,k} x^k e_i + \sum_{j<i,l} \text{const} \cdot x^l e_j.$$

□

EXAMPLE 3.18. Consider the case $n = 2$. The resonance means

(i) $\lambda_1 = k_1\lambda_1 + k_2\lambda_2$ and/or (ii) $\lambda_2 = k_1\lambda_1 + k_2\lambda_2$.

Next we divide the problem into several subcases.

(a) If $\lambda_1 = \lambda_2 = 0$ then all terms in the expansion of the vector field are resonant and nothing can be reduced (by means of Theorem 3.17).

(b) If $\lambda_1 = 0 \neq \lambda_2$ (the s*addle–node* case) of then in (i) we must have $k_2 = 0$ and in (ii) we must have $k_2 = 1$. Thus the Poincaré–Dulac formal normal form is

$$\dot{x} = x^2 f(x), \qquad \dot{y} = \lambda_2 y\bigl(1 + g(x)\bigr).$$

(c) If $\lambda_2/\lambda_1 \geqslant 1$ is a rational number (the case of *resonant node*) then (i) cannot hold and (ii) can hold with $k_1 = \lambda_2/\lambda_1$, $k_2 = 0$ provided that $\lambda_2/\lambda_1 = m$ is integer. The normal form is either linear system or

$$\dot{x} = \lambda_1 x, \qquad \dot{y} = m\lambda_1 y + ax^m.$$

(d) If $\lambda_2/\lambda_1 = -p/q < 0$ is rational (the case of *resonant saddle*) then the normal form is

$$\dot{x} = \lambda_1 x\bigl(1 + f(x^q y^p)\bigr), \qquad \dot{y} = \lambda_2 y\bigl(1 + g(x^q y^p)\bigr).$$

(e) If λ_2/λ_1 is irrational (the non-resonant case) then the normal form is linear.

In some cases the Poincaré–Dulac normal form is analytic.

THEOREM 3.19. (See [67,17].) *If the germ* $V(x)$ *is of the Poincaré type* (*see Definition* 3.16) *then the change* $y = G(x)$ *which reduces it to the polynomial Poincaré–Dulac normal form can be chosen analytic.*

PROOF. (We follow the paper [17] by N. Brushlinskaya.) After changing (if necessary) the time $t \to ct$ we can assume that the eigenvalues lie in the right half-plane, $\operatorname{Re}\lambda_j < 0$.

Note also that there can exist only finitely many resonant relations; for instance in the case (c) of Example 3.18 there is only one such relation. Let $0 < m < -\operatorname{Re}\lambda_j < M$ and let an integer r be such that $\frac{M}{n} < r$. Then all resonant terms $x^k e_i$ have degree $|k| = k_1 + \cdots + k_n < r$. We assume that the part $W(x) = Ax + W_2(x)$ of order $< r$ of the vector field $V(x)$ is in the normal form, $V_1 = V - W = \mathrm{O}(|x|^r)$.

Choose so-called Lyapunov metric $\|\cdot\|$ in $\mathbb{C}^n$, such that for $t > 0$ we have

$$\left\|g^t(x_0)\right\| \leqslant \mathrm{e}^{-mt}\|x_0\|, \qquad \left\|(g^t_*)^{-1}\right\| \leqslant \mathrm{e}^{Mt},$$

where $g^t(x_0)$ is the phase flow map generated by the vector field W (solution $x(t)$ after the time t with initial condition $x(0) = x_0$) and $g^t_* = \frac{\partial g^t}{\partial x_0} = \Psi(t, x_0)$ is the solution of the corresponding variation equation $\dot{\Psi} = \frac{\partial W}{\partial x}\Psi$, $\Psi(0) = I$. If we transform the matrix A to the form $\operatorname{diag}(\lambda_1, \ldots, \lambda_n) + \epsilon A_1$, where A_1 is nilpotent, then the Lyapunov metric is the Hermitian metric associated with this new basis of $\mathbb{C}^n$.

As in other similar situations we reduce the problem to a fixed point problem for some operator which is contracting in suitable Banach space. We consider changes of the form $x = y + G(y)$, where $\|G(y)\| = \mathrm{O}(\|y\|^r)$. As the Banach space we choose the space $E_{r,\rho}$ of vector fields $G(y)$, analytic in a ball $\|y\| \leqslant \rho$ and having zero at $y = 0$ of order r, and with the norm $\|G\|_{r,\rho} = \sup_{\|y\|\leqslant\rho} \|G(y)\|/\|y\|^r$.

Let $L_W G = \frac{\partial G}{\partial y}W - \frac{\partial W}{\partial y}G$ be the Poisson bracket of the vector fields V and G. Then the equation for conjugation of V and W_0 by means of the diffeomorphism $y + G(y)$ leads to the equation

$$L_V G = \Phi(G), \tag{3.10}$$

where $\Phi(G) = V_1(y + G(y)) + W_2(y + G(y)) - W_2(y) - \frac{\partial W_2}{\partial y}G(y)$.

The operator L_W has the right inverse defined by means of the method of characteristics for the non-homogeneous PDE $L_W G = H$. If we put $g(t) = G(g^t(y_0))$ and $h(t) = H(g^t(y_0))$, then we get the equation $\dot{g} - a(t)g = h$, $a(t) = \frac{\partial W}{\partial y}(g^t(y_0))$. Its solution is $g(t) = -\Psi(t, y_0)\int_t^\infty \Psi^{-1}(s, y_0)h(s)\,\mathrm{d}s$, where the latter integral is absolutely convergent. Putting $t = 0$ and $y_0 = y = g^0(y)$ we find

$$G(y) = (L_W^{-1}H)(y) = -\int_0^\infty \Psi^{-1}(t, y)H\bigl(g^t(y)\bigr)\,\mathrm{d}t.$$

Due to the properties of the Lyapunov metric we have $\|H(g^t(y))\|_{r,\rho} \leqslant \|H\|_{r,\rho}\|y\|^r \mathrm{e}^{-rmt}$ and $\|\Psi^{-1}\| \leqslant \mathrm{e}^{Mt}$ and hence the operator L_W^{-1} is bounded.

Finally, standard estimated for the non-linear part $\Phi(G)$ in (3.10) imply that the operator $L_W^{-1} \circ \Phi$ is a contraction on some ball $\{\|G\|_{r,\rho} \leqslant R\}$ in the space $E_{r,\rho}$. □

The next theorem, which concerns the cases of saddle–node and of saddle, was firstly proved by C. Briot and J. Bouquet [15] and can be called the *analytic Hadamard–Perron theorem*. It will be used in further sections.

THEOREM 3.20. *Consider an analytic planar system*

$$\dot{x} = \lambda_1 x + \cdots, \qquad \dot{y} = \lambda_2 y + \cdots$$

such that $\lambda_2 \neq 0$ *and* $\lambda_1/\lambda_2 \leqslant 0$. *Then there exists an invariant analytic curve tangent to* $x = 0$ *at the origin.*

PROOF. In the case of a saddle–node we can assume that $\frac{\mathrm{d}x}{\mathrm{d}y} = \frac{f(x,y)}{\lambda_2 y + g(x,y)}$ where f, g have second order zero at the origin and $f(0, y) = \mathrm{O}(y^3)$. In the case of a saddle we can assume that $\frac{\mathrm{d}x}{\mathrm{d}y} = \frac{\lambda_1 x + f(x,y)}{\lambda_2 y + g(x,y)}$ with f, g having trird order zero at the origin (because the resonant terms in the Poincaré–Dulac normal form start from cubic monomials).

We put the equation of the invariant curve in the form $x = y^2\phi(y)$. In the case of saddle–node we get the equation $y^2\phi' + 2y\phi = f(y^2\phi, y)/(\lambda_2 y + g(y^2\phi, y))$. After division by y^2 it takes the form $\phi' + 2\phi/y = F(y, \phi)$ (F – analytic) which can be written in the integral form

$$\phi(y) = y^{-2}\int_0^y s^2 F\bigl(s, \phi(s)\bigr)\,\mathrm{d}s.$$

The latter equation is solved using the contraction principle in some ball in the Banach space of analytic functions ϕ defined in a disc $|y| < \epsilon$ with the sup-norm.

In the saddle case we arrive to the equation $\phi' = (\lambda - 2)\phi/y + F(y, \phi)$, $\lambda = \lambda_1/\lambda_2 < 0$, or to the integral equation $\phi = y^{\lambda-2}\int_0^y s^{2-\lambda} F(s, \phi(s))\,\mathrm{d}s$. □

3.3. *Ecalle–Voronin moduli*

After the resolution theorem our next task is to describe the analytic classifications of planar holomorphic foliations near elementary singular points. As we have said this theory is practically completed. However before classifying the two-dimensional vector fields we shall present the classification of analogous one-dimensional objects.

These objects are the germs of analytic diffeomorphisms $f : (\mathbb{C}, 0) \to (\mathbb{C}, 0)$:

$$z \to f(z) = \mu z + a_2 z^2 + \cdots. \tag{3.11}$$

DEFINITION 3.21. Two germs f and $\tilde{f}$ of conformal diffeomorphisms of $(\mathbb{C},0)$ are *analytically equivalent* (respectively, *formally equivalent, topologically equivalent)* if there is a germ $h(z)$ of analytic diffeomorphism (respectively, a formal power series $h(z) \sim h_1 z + h_2 z^2 + \cdots$, a homeomorphism $h(z)$) conjugating f with $\tilde{f}$. It means that

$$\tilde{f} = h^{-1} \circ f \circ h.$$

Analogous definition takes place in the case of multi-dimensional diffeomorphisms of $(\mathbb{C}^n,0)$.

The diffeomorphism h transforms the orbits of $\tilde{f}$, i.e. the sets $\{\ldots, (\tilde{f})^{-1}(z), z, \tilde{f}(z), (\tilde{f})^2(z) = \tilde{f} \circ \tilde{f}(z), \ldots\}$, to the orbits of f. Thus f and $\tilde{f}$ have diffeomorphic sets of fixed points and of periodic points of given period.

The following result is an analogue of the Poincaré–Dulac normal form (Theorem 3.17).

THEOREM 3.22. *If the multiplicator μ in* (3.11) *is not a root of unity then the map f is formally linearizable, i.e. it is formally equivalent to the linear map μz.*

If $|\mu| \neq 1$ then f is analytically linearizable.

PROOF. The analogue to the homological equation for changes of the form $z \to z + g_k z^k$ applied to the maps $\mu z + a_k z^k + \cdots$ is following

$$(\mu - \mu^k) g_k = a_k.$$

This gives the first statement of the theorem.

The case $|\mu| \neq 1$ for a diffeomorphism corresponds to the Poincaré type for a vector field. The proof of analyticity of the linearizing transformation repeats the Brushlinskaya's proof of Theorem 3.19. Instead of the continuous flow $\{g^t\}_{t\in\mathbb{R}}$ one should use the discrete cascade $\{f^n\}_{n\in\mathbb{Z}}$. We omit the details. □

We focus our attention on *germs of analytic diffeomorphisms tangent to identity*

$$f(z) = z + az^{p+1} + \cdots, \quad a \neq 0.$$

Note that, after suitable normalization, we can assume that $a = 1$. Following Il'yashenko in [42] we denote the space of such germs by $\mathcal{A}_p$.

PROPOSITION 3.23. *Any germ from $\mathcal{A}_p$ is formally equivalent to the germ*

$$f_{p,\lambda} = g_w^1,$$

where g_w^t is the phase flow map after time t of the vector field

$$w = w_{p,\lambda} = \frac{z^{p+1}}{1 + \lambda z^p} \frac{\partial}{\partial z}$$

and $\lambda \in \mathbb{C}$ is the invariant of the formal classification.

PROOF. We cancel the suitable terms in f by means of the conjugating maps $z \to z + b_l z^l$. Simple calculations show that the leading contribution from this change is the term

$$(l - p - 1) b_l z^{l+p}.$$

If $l \neq p + 1$ then the corresponding power of z in f can be canceled. There remains only the power z^{2p+1}.

Thus the formal normal form is $z + z^{p+1} + \nu z^{2p+1}$. Expanding $f_{p,\lambda}$ into powers of z we see that the latter form is formally equivalent to $f_{p,\lambda}$ for $\lambda = p + 1 - \nu$. □

The space of germs f which are formally equivalent to $f_{p,\lambda}$ is denoted by $\mathcal{A}_{p,\lambda}$.

PROPOSITION 3.24. (See [18,71].) *Any germ from $\mathcal{A}_p$ is topologically equivalent to $g = f_{p,0} = z(1 - z^p)^{-1/p}$.*

PROOF. This proof relies on drawing the phase portrait of the vector field $\dot{z} = z^{p+1}/p$, whose phase flow (with real time) is $g^t(z) = z(1 - tz^p)^{-1/p}$. It consists of $2p$ elliptic sectors and $2p$ parabolic sectors. Next one shows that if we perturb the map g^1 within the class $\mathcal{A}_p$ then the qualitative behavior of the orbits remain the same. We omit the details (which can be found also in [89]). □

The functional moduli of the analytical classification of germs of conformal mappings are connected with the structure of the space of orbits of the action of such a mapping on a neighborhood of the fixed point. It means that we look at the space U^*/f, where $U^* = U \setminus 0$ is a punctured neighborhood of $z = 0$ and points z and $f(z)$ are treated equivalent. (The space U^*/f is Hausdorff, but the analogous space U/f space is not Hausdorff.)

The structure of the orbit space can be better seen in the t-chart where

$$t = t(z) = -1/pz^p + \lambda \ln z$$

is the (complex) time in the vector field $w_{p,\lambda}$. Because the solution of the equation $\dot{z} = w_{p,\lambda}$ is $t = t(z) + \text{const}$, the map $f_{p,\lambda} = g_w^1$ takes the simple form

$$t \to t + 1.$$

Assume, for example, that $\lambda = 0$ (then $t(z)$ is single-valued) and that $p = 1$. Then the neighborhood $U^* = \{|z| < r\}$ is replaced by $W = \{|t| > R\}$. The set W is divided into the vertical strips of width 1. Identifying two sides of such strip we get a cylinder which can be identified with the doubly punctured sphere $\mathbb{C}^*$: $-i\infty \to 0$, $+i\infty \to \infty$. The space $W/(\mathrm{id} + 1)$ consists of two copies of $\bar{\mathbb{C}}$ with identifications near 0 and ∞, like at Fig. 6. The vertical strips from the t-chart correspond to the crescents in the z-chart.

In the general case (λ and p arbitrary and f close to $f_{p,\lambda}$) the chart $t(z)$ is a well defined diffeomorphism in sectors (of width $> 2\pi/p$)

$$S_j = \left\{ \frac{j-2}{2p}\pi - \delta < \arg z < \frac{j}{2p}\pi + \delta \right\},$$

$j = 1, \dots, 2p$, where $\delta > 0$ is small.

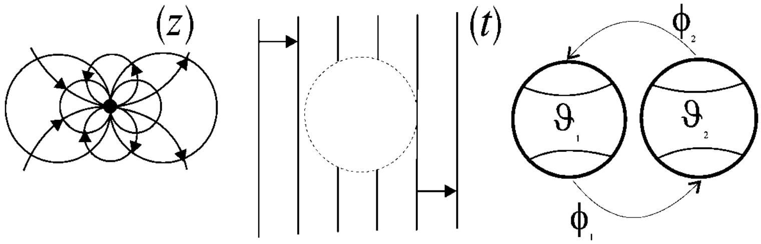

Fig. 6.

The function $t(z)$ sends S_j to $\tilde{S}_j$. In $\tilde{S}_j$ we denote by $t_j = t(z)|_{S_j}$ the local charts, where the branches of $\ln z$ are such that they are real in $S_1 \cap \mathbb{R}$, $t_j = t_{j+1}$ in the intersections $S_j \cap S_{j+1}$ for $j < 2p$ and $t_{2p} = t_1 + 2\pi \mathrm{i}\lambda$.

The maps $f_{p,\lambda}$ and f are replaced by the mappings

$$\tilde{f}_{p,\lambda} : t_j \to t_j + 1,$$

$$\tilde{f} : t_j \to t_j + 1 + R_j(t_j),$$

in $\tilde{S}_j$. Here we can assume that

$$R_j(t) = \mathrm{O}(t^{-M})$$

for some large M. The vertical strips from Fig. 5 and orbit spaces will be only slightly perturbed. The vertical lines are replaced by the iterations of one line, $f^n(l_0)$ where, due to the fact that $R(t)$ is small, there are no intersections between them.

LEMMA 3.25. *Each quotient space $\tilde{S}_j/\tilde{f}$ is conformally equivalent to $\mathbb{C}^*$.*

PROOF. This quotient space, which we denote by T, is obtained from the (non-straight) strip between the lines $l_0 = \{\mathrm{Re}\, t = c\}$ and $\tilde{f}(l_0)$ by identifying its sides. Here $\tilde{f}(c + \mathrm{i}\tau) = c + \mathrm{i}\tau + 1 + R_j(c + \mathrm{i}\tau)$ where $R(t)$ is small.

We treat $\mathbb{C}^*$ as the straight strip $c \leqslant \mathrm{Re}\, t \leqslant c + 1$ with identified sides. It is parametrized by $\theta \in [0, 1]$ and $\tau \in \mathbb{R}$: $t = c + \theta + \mathrm{i}\tau$.

We construct a map from $\mathbb{C}^*$ to T

$$F(c + \theta + \mathrm{i}\tau) = c + \theta + \mathrm{i}\tau + \theta R_j(t).$$

Because $F'_t = 1 + R(t)/2 + \theta R'_j(t)$, $F'_{\bar{t}} = R_j(t)/2$, the map F is quasi-conformal and satisfies the condition of regularity from Proposition 3.74 in Appendix 1. The modulus of quasi-conformality $\mu_F = F'_{\bar{t}}/F'_t$ is small and tends to zero at the ends of the strip $\{c < \mathrm{Re}\, t < c + 1\}$; (they correspond to 0 and ∞ in $\bar{\mathbb{C}}$).

Applying Proposition 3.40 from Appendix 1 we get the assertion of the lemma. □

Therefore, U^*/f is topologically equivalent to $2p$ copies of $\bar{\mathbb{C}}$ with suitable identifications of the neighborhoods of 0 and ∞. More precisely, we have the spheres $\bar{\mathbb{C}} \times \{j\}$, $j = 1, \dots, 2p$, and identifying maps of the form:

$$\phi_j : (\bar{\mathbb{C}}, 0) \times \{j\} \to (\bar{\mathbb{C}}, 0) \times \{j+1\}, \quad j \text{ even},$$
$$\phi_j : (\bar{\mathbb{C}}, \infty) \times \{j\} \to (\bar{\mathbb{C}}, \infty) \times \{j+1\}, \quad j \text{ odd}.$$

The functional invariants of the classification of germs of maps are the invariants of the holomorphic structure on the space U^*/f.

In the spheres one uses conformal coordinates ϑ_j, e.g. $\vartheta_j = \mathrm{e}^{2\pi \mathrm{i} t_j}$ if $f = f_{p,\lambda}$. Generally, $\vartheta_j = \mathrm{e}^{2\pi \mathrm{i}\tau_j}$ for suitable 'times' $\tau_j = t_j + \mathrm{o}(1)$.

ϑ_j are defined uniquely modulo multiplication by a constant. If we have chosen ϑ_1, then ϑ_2 can be taken in such a way that $\vartheta_2 = \phi_1(\vartheta_1) = \vartheta_1 + \mathrm{o}(\vartheta_1)$ as $\vartheta_1 \to \infty$, $\vartheta_3 = \phi_2(\vartheta_2) = \vartheta_2 + o(\vartheta_2)$ is such that $\phi_2'(0) = 1$, etc. However the charts ϑ_{2p} and ϑ_1 near ∞ cannot be correlated in this way. We have $\vartheta_{2p} = \mathrm{e}^{2\pi \mathrm{i} t_{2p}} = \mathrm{e}^{2\pi \mathrm{i} t_1 - 4\pi^2\lambda} = \nu\vartheta_1$. Thus $\phi_{2p}(\vartheta_{2p}) = \nu\vartheta_{2p} + \mathrm{o}(\vartheta_{2p})$, $\nu = \exp(-4\pi^2\lambda)$.

REMARK 3.26. Changing the chart $\vartheta_1 \to C\vartheta_1$ induces the same changes in the spheres $\bar{\mathbb{C}}_j$ and the maps ϕ_j become conjugated by means of C. This non-uniqueness of the charts ϑ_j is equivalent to the non-uniqueness of the 'times', $\tau_j \to \tau_j + \theta$ where $C = \mathrm{e}^{2\pi \mathrm{i}\theta}$, and the non-uniqueness of the coordinate z, $z \to g_w^\theta(z)$.

The above suggests the following definition.

DEFINITION 3.27. Consider the space of collections $\phi = (\phi_1, \dots, \phi_{2p})$ of germs of maps $\phi_j : (\bar{\mathbb{C}}, 0(\infty)) \times \{j\} \to (\bar{\mathbb{C}}, 0(\infty)) \times \{j+1\}$ with identity linear parts for $j < 2p$ and $\phi_{2p}'(\infty) = \nu$. Two such collections ϕ, ϕ' are called *equivalent*, $\phi \sim \phi'$, iff there exists $C \in \mathbb{C}^*$ such that

$$\phi_i \circ C = C\phi_i'.$$

The set of equivalence classes of such ϕ's is *the moduli space* and is denoted by $\mathcal{M}_{p,\lambda}$.

If $f \in \mathcal{A}_{p,\lambda}$, then the construction (with the strips in $\tilde{S}_j$'s and identifications of U^*/f with a collection of glued together Riemann spheres) defines a collection ϕ. Thus we have a mapping from $\mathcal{A}_{p,\lambda}$ to $\mathcal{M}_{p,\lambda}$. It is the first statements of the following *Ecalle–Voronin theorem*.

THEOREM 3.28. (See [28,83].) *There is a map $f \to \mu_f$ from $\mathcal{A}_{p,\lambda}$ to $\mathcal{M}_{p,\lambda}$ with the following properties*:

- *if f and $\tilde{f}$ are holomorphically equivalent then $\mu_f = \mu_{\tilde{f}}$* (*invariance*);
- *if $\mu_f = \mu_{\tilde{f}}$ then f and $\tilde{f}$ are holomorphically equivalent* (*equimodality*);
- *for any class $[\phi] \in \mathcal{M}_{p,\lambda}$ there exists $f \in \mathcal{A}_{p,\lambda}$ such that $[\phi] = \mu_f$* (*realization*).

J. Ecalle proved a variant of this result in 1975. His proof relies on exploiting the Borel transform. S. Voronin's proof appeared in 1981 and it relies on application of analytic methods (almost complex structures and quasi-conformal mappings). Below we present the Voronin's proof (following the Il'yashenko's paper [42]).

However it must be said that the Ecalle–Voronin moduli were already described by G. Birkhoff in 1939 in [12] and partial results appeared in the woks of L. Leau [45] and other mathematicians. Very interesting review of the history of the problem of analytic classification is presented in the lectures of F. Loray [49].

The essential part of the proof of the Ecalle–Voronin theorem is the fact that the dynamics defined by the map f and by the model map are conjugated holomorphically in sectors.

THEOREM 3.29. *In every sector S_j there is an unique analytic diffeomorphism of the form*

$$H_j(z) = z + h_j(z), \quad h_j = \mathrm{o}(z^{p+1}),$$

conjugating f with $f_{p,\lambda}$.

If we skip the assumption $h_j = \mathrm{o}(z^{p+1})$ then we can replace H_j by $g_w^\theta \circ H_j$ for some $\theta \in C$, where g_w^θ is the phase flow generated by the vector field $w = [z^{p+1}/(1 + \lambda z^p)]\partial_z$.

PROOF. It is enough to construct the conjugating diffeomorphisms in the t-charts, i.e. $\tilde{H}_j(t) = t + \tilde{h}_j(t)$, $t \in \tilde{S}_j$. Then $H_i = t^{-1} \circ \tilde{H}_j \circ t$.

The conjugation condition $\tilde{H}_j \circ \tilde{f} = \tilde{f}_{p,\lambda} \circ \tilde{H}_j$, i.e. $t + 1 + R_j + \tilde{h}_j \circ \tilde{f} = t + \tilde{h}_j + 1$, means that

$$\tilde{h}_j = \tilde{h}_j \circ \tilde{f} + R_j.$$

Iterating this equation (with respect to $\tilde{h}_j$) infinitely many times, we find the solution

$$h(t) = \sum_0^\infty R_j \circ \tilde{f}^n(t).$$

The condition $|R_j| < |t|^{-M}$ and the property $\tilde{f}^n(t) \sim \mathrm{const} \cdot n$ ensures that this series is convergent and represents an analytic function of t.

To prove the second statement we compose f with suitable g_w^θ such that $f - f_{p,\lambda} = \mathrm{o}(z^{p+1})$ and apply the first statement. □

Take the system $(H_1, \ldots, H_{2p})$ of germs diffeomorphisms from Theorem 3.29. It can be interpreted as certain Čech cochain. Namely we consider the (non-Abelian) sheaf on S^1 of germs of analytic diffeomorphisms strongly tangent to identity. If U is an open arc in S^1 then the group of sections of this sheaf at U consists of diffeomorphism $H_{S(U)} = \mathrm{id} + h_{S(U)}$, $h_{S(U)}(z) = \mathrm{O}(z^{p+1})$ defines on a sector $S(U)$ with base at U (in the polar coordinates $S(U) = \{z = r\mathrm{e}^{\mathrm{i}\theta}, \theta \in U\}$, see [54]).

The system

$$H = (H_1, \dots, H_{2p})$$

defines the Čech cochain associated with the covering of S^1 induced by the sectors S_i. We consider the coboundary of this cochain, i.e. $\delta H = (\Phi_1, \dots, \Phi_{2p})$

$$\Phi_j = H_{j+1} \circ H_j^{-1}$$

in $S_j \cap S_{j+1}$.

PROPOSITION 3.30.

(a) *The maps Φ_j commute with the standard map $f_{p,\lambda}$.*

(b) *They are exponentially close to identity*

$$\left|\Phi_j(z) - z\right| < \mathrm{e}^{-c/|z|^p};$$

(*equivalently, $H_j - H_{j+1}$ are exponentially small*).

(c) *They are defined uniquely up to conjugation with the map g_w^θ for some $\theta \in \mathbb{C}$.*

(d) *In suitable charts ϑ_j in the spheres $\bar{\mathbb{C}} \times \{j\}$ they define the element μ_f of the moduli space $\mathcal{M}_{p,\lambda}$.*

PROOF. (a) The first statement follows from the identity $H_j \circ f = f_{p,\lambda} \circ H_j$.

(b) The second property follows from the first one. Indeed, in the t-chart the commutativity of the induced map

$$\tilde{\Phi}_j(t) = t + \tilde{\phi}_j(t)$$

with the standard map $t \to t+1$ means that the functions $\tilde{\phi}_j(t)$ are periodic, $\tilde{\phi}_j(t+1) = \tilde{\phi}_j(t)$. Thus $\tilde{\phi}_j$ are expanded into the Fourier series $\sum c_{jl}\mathrm{e}^{2\pi \mathrm{i} l t}$.

The function Φ_j is analytic in $S_j \cap S_{j+1}$, which corresponds to the domain $\operatorname{Im} t > t_0 > 0$ in the $t = t_j$-chart in $\tilde{S}_j$ if j is odd, and to the domain $\operatorname{Im} t < -t_0$ if j is even. Moreover, $\tilde{\Phi}_j(t) = t + \mathrm{o}(t)$ as $t \to \infty$ (because $\tilde{H}_j$ have this property).

This implies that

$$\begin{aligned} \tilde{\Phi}_j(t_j) &= t_j + \sum_{l>0} c_{jl}\mathrm{e}^{2\pi \mathrm{i} l t_j}, && j \text{ odd}, \\ \tilde{\Phi}_j(t_j) &= t_j + \sum_{l<0} c_{jl}\mathrm{e}^{2\pi \mathrm{i} l t_j}, && j \text{ even}, \\ \tilde{\Phi}_{2p}(t_{2p}) &= -2\pi \mathrm{i}\lambda + t_{2p} + \sum_{l<0} c_{jl}\mathrm{e}^{2\pi \mathrm{i} l t_j}. \end{aligned} \tag{3.12}$$

The constant in the latter formula follows from the difference between the local charts $t_{2p} = t_1 + 2\pi \mathrm{i}\lambda$ and t_1.

Now we have $\Phi_j = t_{j+1}^{-1} \circ \tilde{\Phi}_j \circ t_j$ with $t_j = -1/(pz^p) + \lambda \ln z$. If j is odd then we see that $\Phi_j(z) = z + \mathrm{O}(|c_{j1} z^{\alpha} \mathrm{e}^{-2\pi \mathrm{i}/(pz^p)}|)$. Analogous estimates hold in the case of even j.

(c) This point follows from the second statement of Theorem 3.29.

(d) Recall that the moduli space $\mathcal{M}_{p,\lambda}$ is the space of conformal structures on the orbit space U^*/f. Thus we should associate with any system $\tilde{\Phi}$ a system of conformal charts on the spaces S_j/f (or $\tilde{S}_j/\tilde{f}$) and a system of gluing maps between them.

We introduce new charts $\tau_j := \tilde{H}_j(t_j) = t_j + \cdots$ in $\tilde{S}_j$ having the property that they conjugate f with the translation id$+1$. They are also defined by the formulas

$$\tau_j = t_j \circ H_j.$$

One easily checks that $\tau_j \circ f \circ \tau_j^{-1} = \mathrm{id} + 1$. It is also clear that the space $\tilde{S}_j/\tilde{f}$ is conformally equivalent to the τ_j-plane divided by the action of the translation id$+1$.

The identification of $\tilde{S}_j/\tilde{f}$ with $\mathbb{C}^* = \mathbb{C}^* \times \{j\}$ is given by the formula

$$\tau_j \to \vartheta_j = \mathrm{e}^{2\pi \mathrm{i} \tau_j}.$$

The gluing maps $\vartheta_j \to \vartheta_{j+1} = \phi_j(\vartheta_j)$ (see Definition 3.27) arise from the differences between τ_j and τ_{j+1} in $\tilde{S}_j \cap \tilde{S}_{j+1}$. We have $\phi_j = [\exp 2\pi \mathrm{i}(\cdot)] \circ (\tau_{j+1} \circ \tau_j^{-1}) \circ [(1/2\pi \mathrm{i}) \ln(\cdot)]$. Therefore we should find an expression for $\tau_{j+1} \circ \tau_j^{-1}$. We have

$$\tau_{j+1} \circ \tau_j^{-1} = t_{j+1} \circ H_{j+1} \circ H_j^{-1} \circ t_j^{-1} = \tilde{\Phi}_j.$$

If $\tilde{\Phi}_j$ are defined by the formulas (3.12) then $\phi_j(\vartheta_j) = \exp\{2\pi \mathrm{i}[\tau_j + \sum c_{jl} \vartheta_j^l]\}$, or

$$\phi_j = \vartheta_j + \sum d_{j,l} \vartheta_j^l,$$
$$\phi_{2p} = \nu \vartheta_{2p} + \sum d_{jl} \vartheta_{2p}^l.$$

(Above the sums run either over positive or over negative l's.)

Like t_j, the variables τ_j are defined uniquely modulo translation by a constant θ. This means that the charts ϑ_j in $\mathbb{C}^* \times \{j\}$ are defined uniquely modulo multiplication by the constant $C = \mathrm{e}^{2\pi \mathrm{i} \theta}$. □

PROOF OF ECALLE–VORONIN THEOREM 3.28. (a) *Invariance of the class* μ_f. Let f, g be two analytically equivalent germs from the class $\mathcal{A}_{p,\lambda}$, h being the conjugating holomorphism: $h \circ f = g \circ h$. Let H, G be the cochains normalizing f, g respectively. Then the cochain $G \circ h$ normalizes f. Moreover, we find that $g \circ h = g_w^{\theta} \circ H$ (as H and $G \circ h$ conjugate the same f with $f_{p\lambda}$). So

$$G_{j+1} \circ G_j^{-1} = g_w^{\theta} \circ (H_{j+1} \circ H_j^{-1}) \circ g_w^{-\theta}.$$

This means that, if $\tilde{\Phi}$, $\tilde{\Psi}$ are the coboundaries associated with f, g (expressed in the t-charts), then they are equivalent by means of the translation map id$+\theta$. Hence the maps

$\phi_j = [\exp 2\pi \mathrm{i}(\cdot)] \circ \tilde{\Phi}_j \circ [(1/2\pi \mathrm{i}) \ln(\cdot)]$ and $[\exp 2\pi \mathrm{i}(\cdot)] \circ \tilde{\Psi}_j \circ [(1/2\pi \mathrm{i}) \ln(\cdot)]$ are equivalent by means of a rescaling $C \times \mathrm{id}$.

(b) *Equimodality*. Let $\tilde{\Phi}$, $\tilde{\Psi}$ be two collections associated with maps f, g respectively. Assume that they are equivalent by means of translation. Therefore choosing another normalizing cochain we can obtain the coincidence of the cochains $\tilde{\Phi}$ and $\tilde{\Psi}$.

But the identity $G_{j+1} \circ G_j^{-1} = H_{j+1} \circ H_j^{-1}$ is equivalent to

$$H_j^{-1} \circ G_j = H_{j+1}^{-1} \circ G_{j+1}.$$

This means that the maps $H_j^{-1} \circ G_j$ are prolonged to a punctured neighborhood of $z = 0$ as a single valued mapping. By the Riemann removability of singularities theorem we prolong it to an analytic map h in a whole neighborhood of 0.

Moreover, because G_j conjugates g with $f_{p,\lambda}$ and H_j^{-1} conjugates $f_{p,\lambda}$ with f then h conjugates g with f.

(c) *Realization*. Let $\mu \in \mathcal{M}_{p,\lambda}$ be an element of the moduli space. We have to show that $\mu = \mu_f$ for some map f.

We choose a representative $\tilde{\Phi}$ of μ and associated with it the 1-cocycle $\Phi = (\Phi_j)$ of germs of holomorphic maps in the sectors $S_j \cap S_{j+1}$, all but one tangent to the identity.

Consider the disjoint collection of the sectors, i.e. $S_j \times \{j\}$. Denote by z_j the charts induced by (z, j). We glue these sectors using the mappings $\Phi_j : z_{j+1} \sim \Phi_j(z_j)$. We obtain certain topological space $\mathcal{S}$ homeomorphic to a punctured disc. This space has a conformal structure arisen from the coordinates z_j. The space $\mathcal{S}$ (and its closure $\bar{\mathcal{S}}$) admits a homeomorphism f_0 induced from $f_{p,\lambda}$ at each $S_j \times \{j\}$. f_0 is analytic with respect to the conformal structure. Our task is to show that the conformal structure of $\bar{\mathcal{S}}$ coincides with the conformal structure of the punctured disc and that f_0 belongs to $\mathcal{A}_{p,\lambda}$.

Let $\chi_j(z)$ be an infinitely smooth partition of unity associated with the covering S_j. We need that the functions χ_j and their gradients have at worst power type singularities as $z \to 0$.

We construct the map

$$H_0 = \sum \chi_j(z_j) z_j$$

from $\mathcal{S}$ to a punctured disc $D^* \subset \mathbb{C}$.

LEMMA 3.31. *The mapping H_0 is quasi-conformal.*

PROOF. (See Appendix 1.) In $S_j \cap S_{j+1}$ we have $H_0 = \chi_j z_j + \chi_{j+1} z_{j+1} = z_j + (\Phi_j(z_j) - z_j)\chi_{j+1}$ which implies

$$\partial H_0/\partial z_j = 1 + \mathrm{o}(1), \qquad \partial H_0/\partial \bar{z}_j = (\Phi_j - z_j)\partial \chi_{j+1}/\partial \bar{z}_j = \mathrm{o}(1).$$

This means that the almost complex structure, induced on D^* by H_0, is defined by the Beltrami differential $\mu(\mathrm{d}\bar{z}/\mathrm{d}z)$, where $\mu = \mu(H_0^{-1})$ is exponentially small together with its derivatives. □

Let us prolong μ to the whole disc D. By Theorem 3.72 from Appendix 1 the almost complex structure on D is integrable and there exists a diffeomorphic mapping $G : D \to \mathbb{C}$ such that $\mu_G = \mu$. This means that the composition $H = G \circ H_0 : \mathcal{S} \to \mathbb{C}$ is conformal and $\mathcal{S}$ is conformally equivalent to D^*.

The mapping f_0 in $\mathcal{S}$, induced from $f_{p,\lambda}$, is prolonged to a mapping of D. We denote it by f. Of course, it is analytic.

Because the functions μ, G, H are smooth and f is conjugated by means of H with $f_{p,\lambda}$ at the sectors S_j, then their linear parts are also conjugated. So $f'(0) = 1$ and $f \in \mathcal{A}_l$ for some l.

But the index l is a topological invariant (see Proposition 3.24), it is the number of 'elliptic sectors' (divided by 2). So $l = p$.

Finally, the formal classification invariant λ is included into the functional modulus $\tilde{\Phi}_{2p} = -2\pi i\lambda + t_{2p} + \cdots$.

Note that the maps $H_j = z_j \circ H^{-1}$ form the normalizing maps for f (the normalizing cochain). Its coboundary maps are $z_{j+1} \circ z_j{}^{-1} = \Phi_j$. This means that the collection $\tilde{\Phi}$ is the functional modulus for f.

Theorem 3.28 is complete. □

Now we consider conformal maps of the form

$$f(z) = e^{2\pi i m/n} z + \cdots, \tag{3.13}$$

i.e. $f'(0)$ is a primitive root of unity of order n. We call them $m : n$ *resonant maps*.

PROPOSITION 3.32. *Any germ of this form is formally equivalent to*

$$e^{2\pi i m/n} g_w^1, \quad w = \frac{z^{np+1}}{1 + \lambda z^{np}} \frac{\partial}{\partial z}.$$

PROOF. The Poincaré–Dulac theorem for diffeomorphisms allows to reduce f to the form $e^{2\pi i m/n} z(1 + \sum a_l z^{nl})$. Let p be the first index l with non-zero a_l. We can assume that the coefficient $a_p = 1$.

Next, repeating the proof of Proposition 3.21, we successively cancel the terms $a_l z^{nl+1}$ using the changes $z \to z + b_l z^{n(l-p)}$. It is possible to do it in all cases but $l = 2p$. □

One denotes by $\mathcal{A}_{m,n,p,\lambda}$ the space of germs with the formal normal form having the indicated indices.

Let us pass to analytic classification of the germs from $\mathcal{A}_{m,n,p,\lambda}$. Note firstly that f^n is tangent to identity, it belongs to $\mathcal{A}_{q,\beta}$, $q = np$ with some β (determined by λ).

Consider the orbit space U^*/f^n, consisting of $2np$ Riemann spheres $\mathbb{C}^* \times \{j\}$. The map f transforms the orbits of f^n to orbits of f^n and induces the map $\pi_* f : U^*/f^n \to U^*/f^n$. We describe the action of this map on the Riemann spheres.

Note that the sphere $\mathbb{C}^* \times \{j\}$ is the quotient of the sector S_j with the bisectrix $\arg z = \pi(j-1)/(2pn)$ and the transformation f is approximately the rotation by the angle $2\pi m/n$. Therefore $f(S_j) \approx S_{j+2pm}$ and $\pi_* f : \mathbb{C}^* \times \{j\} \to \mathbb{C}^* \times \{j + 2pm\}$.

Moreover, $\pi_* f$ is a holomorphic diffeomorphism and takes the form $\pi_* f(\vartheta_j) = C_j \vartheta_{j+2pm}$. It means also that $\vartheta_{j+2pm} \circ f = C_j^{-1} \vartheta_j$. One can see that $C_j = \mathrm{e}^{2\pi \mathrm{i} r/n}$ is a root of unity.

Indeed, because $\phi_j = \vartheta_{l+1} \circ \vartheta_l^{-1}$ are close to the identity (or to the multiplication by the constant ν for $l = 2pn$) then $\vartheta_{j+2pm+1} \circ \vartheta_{j+2pm}^{-1} = \vartheta_{j+2pm+1} \circ f \circ f^{-1} \circ \vartheta_{j+2pm}^{-1} = C_{j+1}^{-1} \vartheta_{j+1} \circ \vartheta_j^{-1} \circ C_j = C_{j+1}^{-1} \phi_j \circ C_j = \mathrm{id} + \cdots$. So $C_j = C_{j+1} = \cdots = C$. Because $\pi_* f^n = \mathrm{id}$ we get $C^n = 1$.

From the above it follows that only $2p$ first gluing maps are needed to determine the functional modulus $\mu^*_{f^n}$. Indeed, we have $\phi_{j+2pm} = \mathrm{e}^{-2\pi \mathrm{i} r/n} \phi_j \circ \mathrm{e}^{2\pi \mathrm{i} r/n}$. For the last gluing map we get $\phi_{2pn} = \nu \mathrm{e}^{-2\pi \mathrm{i} r/n} \phi_{2p(n-m)} \circ \mathrm{e}^{2\pi \mathrm{i} r/n}$, where $\nu = \phi'_{2pn}(\infty)$ is the constant expressed by the formal modulus λ.

All this leads to the following result.

THEOREM 3.33. (See [42].) *The space $\mathcal{A}_{m,n,p,\lambda}$ of germs of conformal diffeomorphism modulo analytic equivalence is in one-to-one correspondence with the space $\mathcal{M}_{m,n,p,\lambda}$ of systems*

$$\phi = (\phi_1, \dots, \phi_{2p})$$

(*of germs of analytic diffeomorphisms $\phi_j(\bar{\mathbb{C}}, 0) \to (\bar{\mathbb{C}}, 0)$ $(j$ odd$)$ or $\phi_j(\bar{\mathbb{C}}, \infty) \to (\bar{\mathbb{C}}, \infty)$ $(j$ even$)$ with identity linear parts*) *modulo the equivalence $\phi \sim D\phi \circ D^{-1}$.*

3.4. *Martinet–Ramis moduli*

The saddle–node singularity of analytic planar vector field is such that one of its eigenvalues vanishes and the other eigenvalue is non-zero. Firstly we present the formal classification of saddle–nodes and next we describe the moduli of their analytic classification.

PROPOSITION 3.34. *Any complex analytic saddle–node is formally orbitally equivalent to*

$$\dot{x} = x^{p+1}, \qquad \dot{y} = -y(1 + \lambda x^p).$$

PROOF. The Poincaré–Dulac theorem 3.17 and Example 3.18(b) give the following (non-orbital) normal form $\dot{x} = a_{p+1} x^{p+1} + a_{p+2} x^{p+2} + \cdots$, $\dot{y} = \lambda_2 y(1 + b_1 x + b_2 x^2 + \cdots)$, where $a_{p+1} \neq 0$; if all $a_j = 0$ then the singular point would have infinite multiplicity (non-isolated in the complex analytic case). By linear changes of variables and time we can assume that $a_{p+1} = 1$, $\lambda_2 = -1$.

Now we divide the field by $1 + b_1 x + \cdots$ what gives $\dot{y} = y$ and

$$\dot{x} = x^{p+1}(1 + c_1 x + \cdots). \tag{3.14}$$

Therefore the problem is reduced to formal *non-orbital* classification of 1-dimensional saddle–nodes (3.14).

The latter problem is solved in the same way as in the proof of Theorem 3.23 (about formal classification of diffeomorphisms $z+z^{p+1}+\cdots$). Moreover, this special change can be made analytic. Using the changes $x\to x+d_lx^l$, we obtain the (leading) term $(l-p-1)d_lx^{l+p}\partial_x$ in the transformed vector field. If $l\neq p+1$, then the corresponding monomial vector field can be canceled. There remains only the field $w_{p,\nu}=x^{p+1}(1+\nu x^p)\partial_x$ where ν is the formal invariant.

Of course, one can fix also other terms in ∂_x, like $x^{p+1}(1-\lambda x^p+(\lambda x^p)^2-\cdots)=x^{p+1}(1+\lambda x^p)^{-1}$, $\lambda=-\nu$. Multiplication of this vector field by $1+\lambda x^p$ gives the vector field from thesis of the proposition. □

The integer p is called the *codimension* of saddle–node and $\lambda\in\mathbb{C}$ is the *modulus of formal classification*. The space of germs with the formal normal form as in Proposition 3.34 will be denoted by $\mathcal{E}_{p,\lambda}$.

As we shall see, the normal form from Proposition 3.34 is not analytic. However some of its statements have analytic equivalents. Note that it has two formal invariant curves: the *strong manifold* $x=0$ and the formal *center manifold* $y=0$. By Theorem 3.20 the strong manifold is always analytic but usually the center manifold is not analytic.

EXAMPLE 3.35. (See [33].) The equation $\mathrm{d}y/\mathrm{d}x=(y-x)/x^2$ has the following unique formal solution $y=\sum_1^\infty(n-1)!x^n$ passing through 0.

LEMMA 3.36. *There exist local analytic coordinates and an analytic change of time which give the following initial analytic form*

$$\dot{x}=x^{p+1},\qquad \dot{y}=-y(1+\lambda x^p)+g_0(x)+y^2g_2(x,y),$$

where g_0, y^2g_2 *have zero of order* $\geqslant p+2$ *at the origin.*

PROOF. Since the strong manifold is analytic we can assume that the vector field has the form (in some analytic coordinates) $\dot{x}=xf(x,y)$, $\dot{y}=-y+g(x,y)$. This preliminary form is not satisfactory to our purposes. We want to get the factor x^{p+1} in the first component.

This is done using series of the analytic changes $x\to x+x^j\psi_j(y)$, $j=1,\dots,p$. Let $\dot{x}=x[\phi_1(y)+\mathrm{O}(x^2)]$ where $\phi_1(0)=0$. Then we use the change $x=x_1(1+\psi_1(y))$ such that $-y\psi_1'+\phi_1(y)=0$. Similarly, further terms $x^j\phi_j(y)$, $\phi_j(0)=0$, for $j=2,\dots,p$, are removed from $\dot{x}$. Thus we can put $\dot{x}=x^{p+1}$ and $\dot{y}=g_0(x)+yg_1(x)+y^2g_2(x,y)$.

Moreover, using polynomial changes in y we can cancel some initial terms from g_0 and g_2. The function $g_1(x)$ is reduced to $-1-\lambda x^p$ by a change like in the proof of Proposition 3.34; it turns out to be analytic. □

We define the *extended sectors*

$$T_j=S_j'\times\{|y|<\epsilon\}$$

where $S_j'=\{|x|<\epsilon,\ \frac{(2j-1)\pi}{2p}-\alpha<\arg x<\frac{(2j-1)\pi}{2p}+\alpha\}=\mathrm{e}^{\pi\mathrm{i}/2p}S_j$, $\alpha\in(\frac{\pi}{2p},\frac{\pi}{p})$ are sectors rotated with respect to the sectors S_i from the previous subsection. The following important result belongs to M. Hukuhara, T. Kimura and T. Matuda. Its proof is postponed to Appendix 2.

THEOREM 3.37. (See [40].) *In each extended sector T_j there exists a unique analytic diffeomorphism*

$$H_j(x,y) = \bigl(x, y + \tilde{H}_j(x,y)\bigr), \quad \tilde{H}_j = \mathrm{O}(x^{p+1}),$$

conjugating the system from Lemma 3.36 *with its formal normal form from Proposition* 3.34.

We pass to description of the Martinet–Ramis moduli of analytical orbital equivalence of germs from $\mathcal{E}_{p,\lambda}$.

The reader can guess that these moduli are constructed using the differences between the normalizing diffeomorphisms,

$$\Phi_j = H_{j+1} \circ H_j^{-1} \quad \text{in } T_j \cap T_{j+1}.$$

However, the description of the Φ_j's can be simplified.

Notice that the diffeomorphisms Φ_j keep the first coordinate fixed and preserve the formal normal form $\omega_0 = x^{p+1}\,\mathrm{d}y + y(1+\lambda x^p)\,\mathrm{d}x = 0$ (of the corresponding Pfaff equation). The latter fact gives series of restrictions onto possible forms of Φ_j's.

Let us look at the behavior of the leaves of the foliation defined by $\omega_0 = 0$ in the sectors $T_j \cap T_{j+1}$. These leaves are given by

$$y = C\mathrm{e}^{-t(x)}, \quad t(x) = t_j(x) = -1/(px^p) + \lambda \ln x, \quad C \in \mathbb{C},$$

and the first integral takes the form

$$h(x,y) = h_j(x,y) = y\mathrm{e}^{t(x)} = y\mathrm{e}^{t_j(x)}.$$

(Because of $\ln x$ in the definition of $t(x)$ we index the 'times' and first integrals in different sectors. Thus $t_{2p} = t_1 + 2\pi\mathrm{i}\lambda$, $h_{2p} = \mathrm{e}^{-2\pi\mathrm{i}\lambda}h_1$.)

The neighborhood of $x = y = 0$ is divided into sectors of two types:

- the sectors of *jump* where $\operatorname{Re} x^{-p} \to +\infty$ and $\mathrm{e}^{-t(x)} \to \infty$ (in particular, $\{x > 0\}$ lies in a sector of jump $T_{2p} \cap T_1$),
- the sectors of *fall* where $\operatorname{Re} x^{-p} \to -\infty$ and $\mathrm{e}^{-t(x)} \to 0$.

In the sectors of jump only one leaf approaches the singularity, it is the *local center manifold*. Other leaves diverge as $x \to 0$.

In the sectors of fall all the leaves are indistinguishable. All approach the singularity. We see also that the extended sectors $T_{j+1} \cap T_j$ lie wholly either in the sectors of jump or in the sectors of fall.

PROPOSITION 3.38. *The transition diffeomorphisms Φ_j take the forms*

$$\Phi_j(x,y) = \bigl(x, \phi_j(h_j)\mathrm{e}^{-t_{j+1}}\bigr),$$

where

$$\phi_j(h) = a_j + h, \quad a_j \in \mathbb{C},$$

if $T_{j+1} \cap T_j$ *lies in a sector of fall,*

$$\phi_j(h) = h + \alpha_{j,2}h^2 + \cdots,$$

if $T_{j+1} \cap T_j$ *lies in a sector of jump and* $j \neq 2p$, *and*

$$\phi_{2p}(h) = \mathrm{e}^{-2\pi \mathrm{i}\lambda}h + \alpha_{2p,2}h^2 + \cdots.$$

Moreover Φ_j *tend to* id *exponentially fast as* $x \to 0$.

PROOF. The first statement follows from the fact that Φ_j preserve the formal normal form. So if h_{j+1} is the first integral in T_{j+1} then the function $h_{j+1} \circ \Phi_j$ is the first integral in $T_j \cap T_{j+1}$. But also h_j is a first integral. Thus the first integral is a function of the second first integral, $h_{j+1} \circ \Phi_j = \phi_j \circ h_j$.

In the coordinates (x, h) the map Φ_j is equal to $(x, \phi_j(h))$. Passing to the (x, y) coordinates we get the formula for Φ_j.

The proof of the further statements relies on the fact that $\Phi_j - \mathrm{id} = \mathrm{O}(x^{p+1})$.

Let $T_j \cap T_{j+1}$ be a sector of fall. We have $t_j = t_{j+1}$ (because $j \neq 2p$) and $\mathrm{Re}\, t(x) \to \infty$. Let the Taylor expansion of ϕ_j be $\sum_{n=0}^{\infty} \alpha_{j,n}h^n$. Then

$$\Phi_j = \Bigl(x, \alpha_{j,0}\mathrm{e}^{-t(x)} + \alpha_{j,1}y + \sum \alpha_{j,n}y^n \mathrm{e}^{(n-1)t(x)}\Bigr).$$

The condition $\Phi_j \to id$ implies that $\alpha_{j,1} = 1$ and $\alpha_{j,2} = \alpha_{j,3} = \cdots = 0$. This means that ϕ_j is a translation. Note also that in this case $\Phi_j - \mathrm{id} = (0, \mathrm{O}(\mathrm{e}^{-t(x)}))$ is exponentially small.

Let $T_j \cap T_{j+1}$ be a sector of jump and $j \neq 2p$. Then, acting exactly in the same manner as in the previous case, we get $\alpha_{j,0} = 0$ and $\alpha_{j,1} = 1$. It means that ϕ_j is a germ of diffeomorphism of $(\mathbb{C}, 0)$ with $\phi'(0) = 1$. In this case $\Phi_j - \mathrm{id}$ is exponentially small too.

Let $j = 2p$. We are in the sector of jump with $\mathrm{e}^{t_{2p}} = \mathrm{e}^{2\pi \mathrm{i}\lambda}\mathrm{e}^{t_1}$. We have $\Phi_{2p} = (x, \phi_{2p}(h_{2p})\mathrm{e}^{-t_1}) = (x, \mathrm{e}^{2\pi \mathrm{i}\lambda}\phi_{2p}(h_{2p})\mathrm{e}^{-t_{2p}})$. Analogously as in the previous case we get the formula for ϕ_j and the exponential closeness to the identity. □

The fact that the diffeomorphisms Φ_j have different forms can be explained geometrically. In the sector of jump the values of the first integral are bounded, $h \in (\mathbb{C}, 0)$. In the sectors of fall the first integral takes values in the Riemann sphere $\bar{\mathbb{C}}$ and $h = \infty$ along the strong manifold $x = 0$; the corresponding map ϕ_j is an automorphism of this sphere satisfying $\phi_j(\infty) = \infty$.

The collection of ϕ_j's satisfying the properties of Proposition 3.38 do not yet form a complete set of invariants. The reader can notice that the coordinates in the normalized Pfaff equation $\omega_0 = 0$ are not unique. Its non-uniqueness lies in the possibility to multiplication of y by a constant. This gives the non-uniqueness of the choice of the local first integral: $h_j \to Ch_j$, where C is the same in each sector.

DEFINITION 3.39. Two collections $\phi = (\phi_1, \dots, \phi_{2p})$ and $\tilde{\phi} = (\tilde{\phi}_1, \dots, \tilde{\phi}_{2p})$, satisfying the conditions from Proposition 3.38, are called *equivalent* iff they are conjugated by a linear transformation: $\phi_j \circ C = C\tilde{\phi}_j$.

The equivalence class $[\phi]$ of such a collection is called the *Martinet–Ramis modulus*. The space of Martinet–Ramis moduli is denoted by $\mathcal{N}_{p,\lambda}$.

The above construction of the Martinet–Ramis modulus, associated to saddle–node, defines a map from $\mathcal{E}_{p,\lambda} \to \mathcal{N}_{p,\lambda}$

$$V \to \epsilon_V.$$

The following result is known as the *Martinet–Ramis theorem*.

THEOREM 3.40. (See [54].) *The map $V \to \epsilon_V$ has the following properties*:

- *it sends orbitally analytically equivalent germs of vector fields to the same point* (*invariance*);
- *if $\epsilon_V = \epsilon_{V'}$ then V and V' are orbitally analytically equivalent* (*equimodality*);
- *for any $\epsilon \in \mathcal{N}_{p,\lambda}$ there exists $V \in \mathcal{E}_{p,\lambda}$ such that $\epsilon = \epsilon_V$* (*realization*).

PROOF. The first two points are proved in the same way as the analogous points of the Ecalle–Voronin theorem 3.28. Only the realization property needs separate arguments.

Assume that we have an element from $\mathcal{N}_{p,\lambda}$ which is an equivalence class with some representative $\phi = (\phi_j)$. These ϕ_j define the diffeomorphisms Φ_j in the extended sectors $T_j \cap T_{j+1}$ (see Proposition 3.38).

Take disjoint union of the extended sectors $\bigsqcup T_j \times \{j\}$ and glue them using the Φ_j as the gluing maps. We obtain certain (real) 4-dimensional manifold $\mathcal{S}$. In each $T_j \times \{j\}$ we have the ‘coordinates’ $z_j = (x, y_j)$ and $z_{j+1} = \Phi_j(z_j)$ at the glued part.

Note also that $\mathcal{S}$ is equipped with a foliation $\mathcal{F}_0$ such that in each T_j it is the foliation of the vector field in the formal normal form. We have to define certain complex structure on $\mathcal{S}$ such that the foliation $\mathcal{F}_0$ arises from a holomorphic vector field with saddle–node singularity.

Firstly one defines the map $H_0 : \mathcal{S} \to W \subset \mathbb{C}^2 \setminus \{x = 0\}$ as

$$H_0 = \sum \chi_j z_j$$

where $\{\chi_j\}$ is a partition of unity of $\mathcal{S}$ associated with the covering (T_j) with regular properties as $x \to 0$.

H_0 defines an almost complex structure on W, the image of the complex structures on T_j. By definition this almost complex structure is integrable (see Definition 3.67 in Appendix 1). By Theorem of Newlander–Nirenberg 3.70 (in Appendix 1) the torsion of this almost complex structure vanishes identically.

It turns out that the almost complex structure from W can be prolonged smoothly to an almost complex structure on a full neighborhood of 0 in $\mathbb{C}^2$. Indeed, the almost complex structure is defined by $(1,0)$-forms $\mathrm{d}x$ and $\mathrm{d}y$, where $\mathrm{d}x$ is good (with zero derivative). Since $y = \sum \chi_j y_j$. In $T_j \cap T_{j+1}$, we have $y = \chi_j y_j + \chi_{j+1} y_{j+1} = y_j + h_j(x, y_j)\chi_j$

(see Theorem 3.37). Thus $\mathrm{d}y = \mathrm{d}y_j + \mathrm{o}(1)$, where the term $\mathrm{o}(1)$ is exponentially small as $x \to 0$.

The torsion of the latter almost complex structure is also equal to zero. Applying again the Newlander–Nirenberg theorem, we show that this almost complex structure is integrable. It means that it is equal to the transportation of the standard complex structure by means of some differentiable map $G : (\mathbb{C}^2, 0) \to (\mathbb{C}^2, 0)$

The composition $H = G^{-1} \circ H_0 : \mathcal{S} \to \mathbb{C}^2$ is holomorphic on $\mathcal{S}$ and prolongs to the closure of $\mathcal{S}$. It transforms the foliation $\mathcal{F}_0$ to a foliation $\mathcal{F}$ in $(\mathbb{C}^2, 0)$.

The foliation $\mathcal{F}$ is a saddle–node foliation with the Martinet–Ramis invariant equal to $[\phi]$. □

The Martinet–Ramis theorem allows to solve the problem of analyticity of the center manifold and to explain the reason of non-analyticity of the Euler's solution. Note that in each sector of jump the local center manifold is defined uniquely, using topological criteria. It is the only leaf of the holomorphic foliation containing the singular point in its closure. This local center manifold prolongs itself (uniquely) to the adjacent sectors of fall. The gluing map Φ_j in the sectors of jump leave this local center manifold invariant, $\phi_j(0) = 0$.

The problem is whether the local center manifolds from different sectors of jump lie in one leaf of the foliation. It means, whether the gluing maps in the sectors of fall preserve the two prolongations of the local center manifolds (from the adjacent sectors of jump). This condition reads as $\phi_j(0) = 0$, where $\phi_j(h) = h + a_j$.

We have proved the following result.

COROLLARY 3.41. *A saddle–node singularity has analytic center manifold iff all* $a_j = 0$ *in its Martinet–Ramis modulus. In other words this modulus has the form* $(\mathrm{id}, \phi_2, \mathrm{id}, \phi_4, \ldots, \phi_{2p})$.

3.5. *Holonomy maps and normal forms for resonant saddles*

Here we finish the description of analytic normal forms for germs of planar vector fields with elementary singular points.

The singular points from the *Poincaré domain* have analytic Poincaré–Dulac normal form. This means that the normalizing transformation can be chosen analytic (see Theorem 3.19).

Therefore, it remains to investigate the saddles, i.e. singularities with negative ratio of eigenvalues $-\lambda < 0$. The saddles are of two kinds: *resonant* (i.e. with rational $\lambda = m/n$) and *non-resonant*.

The description of moduli of resonant saddles relies on the classification of germs of resonant 1-dimensional diffeomorphisms and was completed firstly by J. Martinet and J.-P. Ramis [55].

The problem of analytic conjugation of non-resonant saddles is analogous to the problem of analytic linearization of germs of non-resonant 1-dimensional diffeomorphisms and was solved by J.-C. Yoccoz [87] (see Subsection 3.7).

In classification of saddle singularities the following notion is useful.

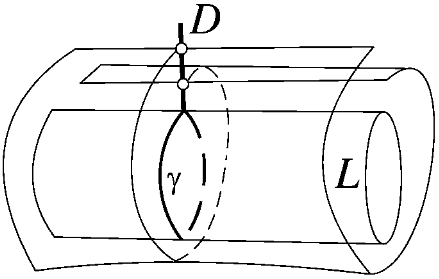

Fig. 7.

DEFINITION 3.42. Let $\mathcal{F}$ be a holomorphic foliation in a 2-dimensional complex manifold, L be a non-singular leaf of $\mathcal{F}$ and $\gamma \subset L$ be a closed loop with beginning at a point x_0. Take a small holomorphic disc D transversal to L at x_0 and parameterized by $z \in (\mathbb{C}, 0)$, $z(x_0) = 0$. We can cover the loop γ by open sets U_i, where the foliation is the flow-box foliation: $\mathcal{F}|_{U_i} = \{dy = 0\}$.

Let $z \in D$. Take a leaf $L(z)$ passing through z. In each U_i we can lift the path $\gamma \cap U_i$ to the leaf $L(z) \cap U_i$. After returning of γ to the point x_0, the lifted curve intersects the disc D again. However the intersection point can differ from z (see Fig. 7). We denote it by $\Delta_\gamma(z)$. We define the *monodromy transformation* (or the *holonomy transformation)* associated with the loop γ as the map

$$z \to \Delta_\gamma(z).$$

The holonomy map Δ_γ is a local holomorphic diffeomorphism (by analytic dependence of solutions on initial conditions). It does not depend on the homotopy class of the loop γ (for fixed D); this is a consequence of the theorem about monodromy. The change of the section D and of the initial point x_0 results in internal conjugations of Δ_γ in the group $\mathrm{Diff}(\mathbb{C}, 0)$ of germs of holomorphic diffeomorphisms of $(\mathbb{C}, 0)$.

The connection between *saddles* and one-dimensional maps lies in the holonomy transformation associated with any of its separatrices. (Recall that, by the analytic Hadamard–Perron theorem, Theorem 3.20, the saddle has both separatrices analytic.) We can assume that

$$\dot{x} = \lambda x(1 + \cdots), \qquad \dot{y} = -y(1 + \cdots).$$

Consider the monodromy transformation $\Delta(x)$ corresponding to a loop in the separatrix $x = 0$. One can easily check that

$$\Delta(x) = \mathrm{e}^{-2\pi \mathrm{i}\lambda} x + \cdots.$$

The following result was firstly proved by J. Mattei and R. Moussu.

PROPOSITION 3.43. (See [56].) *Two germs with saddle singularity with the same ratio* $-\lambda$ *are analytically orbitally equivalent iff the corresponding germs of monodromy maps are analytically equivalent.*

PROOF. If two germs of vector fields are orbitally equivalent then restriction of the conjugating map H to a disc D transversal to $\{x=0\}$ defines a conjugation of monodromies (in D and in $H(D)$).

Let the monodromies be conjugated. Consider two copies of $(\mathbb{C}^2,0)$ with foliations $\mathcal{F}$ and $\mathcal{F}'$ (by the phase curves L, L' of the two vector fields V and V'). In each copy we consider the fibration $\pi:(x,y)\to y$. Their fibers outside $y=0$ are transversal to the leaves of the foliations $\mathcal{F}$ and $\mathcal{F}'$. We denote by $\mathcal{F}_0$ the foliation by the fibers $y=\text{const}$.

Take two discs $D=\{y=\epsilon,\,|x|<\epsilon\}$ and $D'=\{y=\epsilon,\,|x|<2\epsilon\}$. Let $h:D\to D'$ be the map conjugating the monodromies.

We extend the map h to a map $H_0\colon A\to A'$, where $A=\{|x|<\epsilon,\,\epsilon/2<|y|<\epsilon\}$, $A'=\{|x|<2\epsilon,\,\epsilon/2<|y|<\epsilon\}$ are ring-like domains. H_0 preserves the foliation $\mathcal{F}_0$, i.e. $H_0(x,y)=(F(x,y),y)$ and sends leaves L of the foliation $\mathcal{F}$ to leaves L' of the foliation $\mathcal{F}'$. Because of the transversality of the fibers $y=\text{const}$ to the leaves L,L' in the domains A and A' the prolongation H_0 is locally analytic and unique.

H_0 is single-valued in the whole domain A. Indeed, the change of H_0, as the argument turns around the axis $y=0$, is equal to the composition of the monodromy map (defined by $\mathcal{F}$) and of H_0. Because $h=H_0|_D$ conjugates the monodromies the map H_0 is univalent, i.e. $H_0(x,y)$ is meromorphic in y.

Some additional arguments allow to eliminate the possibility that H_0 would have a pole along $y=0$. We refer the reader to [56,54] and [75]. □

Consider firstly the case when $\lambda=-m/n$, $\gcd(m,n)=1$, is a rational number. We call such singular point a *$m:n$ resonant saddle*. Then the monodromy map $\Delta=\mathrm{e}^{2\pi\mathrm{i}m/n}x+\cdots$ is a resonant one-dimensional map considered in Subsection 3.3. Its formal normal form is of one of the following types $\mathrm{e}^{2\pi\mathrm{i}m/n}g_w^1$, $w=[z^{np+1}/(1+\alpha z^{np})]\frac{\partial}{\partial z}$ (see Proposition 3.32). The space of such maps was denoted by $\mathcal{A}_{m,n,p,\alpha}$.

The above form for diffeomorphism corresponds to the following formal orbital normal form for vector fields

$$\dot{x}=x,\quad \dot{y}=y\bigl(-m/n+u^p(1+\lambda u^p)^{-1}\bigr),\quad u=x^my^n, \tag{3.15}$$

where $\lambda=2\pi\mathrm{i}n\alpha$. (The proof relies on passing to the variables x,u in the Poincaré–Dulac normal form and further applying the reduction as in the case of saddle–node.) We denote the class of analytic saddles with the formal orbital normal form (3.15) by $\mathcal{B}_{m,n,p,\lambda}$.

THEOREM 3.44. (See [55].) *The space of classes of analytical orbital equivalence of vector fields from the class* $\mathcal{B}_{m,n,p,\lambda}$ *is the same as the space of classes of analytical equivalence of diffeomorphisms from the class* $\mathcal{A}_{m,n,p,\alpha}$ *described in Theorem* 3.33.

REMARKS ABOUT THE PROOF. In view of Proposition 3.41 the proof of this theorem is reduced to demonstration of the surjectivity of the map $V\to\Delta$ from $\mathcal{B}_{m,n,p,\lambda}$ to $\mathcal{A}_{m,n,p,\alpha}$.

One has to show that any resonant map arises from some resonant saddle as its holonomy. The construction of V is analogous to the construction of the realization parts of the Ecalle–Voronin and Martinet–Ramis classification theorems. We refer the reader to [42]. □

Also with a saddle–node singularity some holonomy transformation can be associated and its relation with the Martinet–Ramis moduli can be studied.

Indeed, the strong invariant manifold of a saddle–node singularity V consists of two leaves of the holomorphic foliation defined by V: the singular point and the leaf L diffeomorphic to a punctured disc. Take a loop $\gamma \subset L$ generating its fundamental group. Using Definition 3.42, we associate with γ the monodromy transformation $\Delta = \Delta_\gamma$.

Recall that $\mathcal{A}_{p,\alpha}$ is the space of germs from $\mathrm{Diff}(\mathbb{C}, 0)$ formally equivalent to the time 1 flow map generated by the vector field $w = [z^{p+1}/(1 + \alpha z^p)]\partial_z$ (see Proposition 3.23).

THEOREM 3.45.

(a) *If* $V \in \mathcal{E}_{p,\lambda}$ *then* $\Delta \in \mathcal{A}_{p,\alpha}$, $\alpha = 2\pi \mathrm{i}\lambda$.

(b) *The Martinet–Ramis modulus of* V *coincides with the Ecalle–Voronin modulus of* Δ. *It means that two vector fields are orbitally analytically equivalent iff their monodromy maps are analytically conjugated. In particular, we have an embedding of the set of equivalence classes of vector fields* $\mathcal{E}_{p,\lambda}/(anal)$ *into the set of equivalence classes of diffeomorphisms* $\mathcal{A}_{p,\alpha}/(anal)$ (*i.e. embedding of the moduli space* $\mathcal{N}_{p,\lambda}$ *into the moduli space* $\mathcal{M}^*_{p,\alpha}$).

PROOF. The first statement can be checked for the vector field in its formal normal form. Then we have $L = \{x = 0 \neq y\}$, $\gamma = \{(0, \mathrm{e}^{\mathrm{i}t})\}$ and the foliation is given by $\frac{\mathrm{d}x}{\mathrm{d}t} = \frac{\mathrm{d}x}{\mathrm{d}\ln y} = x^{p+1}/(1 + \lambda x^p) = w_{p,\lambda}$. The monodromy map Δ is given by the time $2\pi\mathrm{i}$ flow map $\Delta = \exp[2\pi \mathrm{i} w_{p,\lambda}] = \exp[w_{p,\alpha}]$.

To prove the second statement let us keep Δ formally equivalent to $g_w^{2\pi\mathrm{i}}$. Then the sectors S_j (from Theorem 3.29) are turned by the angle $\pi/2p$; we denote them by S'_j. The extended sectors T_j are of the form $S'_j \times \{|y| < \epsilon\}$. We fix also the disc $D = \{y = y_0\}$ transversal to the axis $\{x = 0\}$.

The extended sectors contain complete lifts (to the leaves of the foliation) of the loop in the strong manifold appearing in the definition of the holonomy map.

The normalization diffeomorphisms $H_j(x, y)$ in T_j (from Theorem 3.37) define altogether the normalization diffeomorphisms for the monodromy map Δ in $S'_j \times \{y_0\} \subset D$. They define the local parametrization of S_j by means of the first integral $h_j(x) = h \circ H_j|_{S'_j \times \{y_0\}}$. In the charts h_j the map Δ is equal to the formal normal form.

The transition diffeomorphisms $H_{j+1} \circ H_j^{-1}$ are expressed by means of the one-dimensional transition maps $h_{j+1} \circ h_j^{-1}$. The latter define the Martinet–Ramis moduli as well as the Ecalle–Voronin moduli. □

REMARK 3.46. The image of the embedding from the point (b) of the last theorem forms a proper subset of the set $\mathcal{M}^*_{p,\lambda}$. It is because the diffeomorphisms ϕ_j are subject to the restrictions from Proposition 3.36, $\phi_j = h + a_j : (\bar{\mathbb{C}}, \infty) \to (\bar{\mathbb{C}}, \infty)$ (j odd).

It turns out that the correspondence $V \to \Delta$ is not one-to-one even at the level of topological equivalences; i.e. the sets $\mathcal{E}_{p,\lambda}/top$ and $\mathcal{A}_{p,\lambda}/top$ are really different. (At the level of formal equivalences it is one-to-one.)

As the first example we consider the case with the Martinet–Ramis modulus equal to $(\mathrm{id}+a_1, \mathrm{id}, \mathrm{id}+a_2, \mathrm{id}, \dots, \mathrm{id})$ with some $a_j \neq 0$. The monodromy map Δ is topologically equivalent to its formal normal form (see Proposition 3.22) but the vector field is not equivalent to its formal normal form because it does not have analytic center manifold.

Another example concerns the case with $\lambda = 0$ and with all $a_j = 0$, i.e. with analytic center manifold. We consider the monodromy map Δ_c associated with the leaf L_c containing the center manifold. The topology of the foliation determines the topological type of Δ_c, which is determined by the order of tangency of Δ_c to identity (see Proposition 3.24). So the class $[\Delta]_{top}$ is fixed, but there can be infinitely many classes $[\Delta_c]_{top}$.

3.6. *Geometric realization of Martinet–Ramis moduli*

Unlike the Ecalle–Voronin moduli the Martinet–Ramis moduli can be sometimes calculated explicitly. In this subsection we present a result of P. Elizarov about dependence of the Martinet–Ramis moduli on the vector field itself and we give examples (due to the author and L. Teyssier) of explicit calculation of these moduli.

We begin with definitions of the Borel transform and Gevrey series.

DEFINITION 3.47. Let $f(t) = \sum_{k=0}^{\infty} a_k t^k$ be a formal power series. Its *Borel transform* is the series

$$(\mathcal{B}f)(\tau) = \sum_{k=1}^{\infty} \frac{1}{(k-1)!} a_k \tau^k.$$

By analog to the above standard Borel transform we introduce the following modified Borel transforms

$$(\mathcal{B}^l_{SN} f)(\tau) = \sum_{k=1}^{\infty} \frac{k}{\Gamma(1 + (k + \lambda l)/p)} a_k \tau^k$$

and

$$(\mathcal{B}^l_S f)(\tau) = \sum_{k=1}^{\infty} \frac{k}{\Gamma(1 + (km - \lambda l)/(pm^2))} a_k \tau^k.$$

DEFINITION 3.48. Let the series $f(t)$ as above is an asymptotic expansion of a function, denoted also by f, which is holomorphic in a sector S with vertex at $t = 0$. We say that f is of *Gevrey type of order* s if

$$|a_k| \leqslant C(k!)^{s-1} A^k$$

and

$$\left| f(t) - \sum_{j=1j}^{k-1} t^j \right| \cdot |t|^k \leqslant C(k!)^{s-1} A^k,$$

where the constants A, C depend on f and the sector S. The series f of Gevrey type of order

$$s = 1 + 1/p$$

is called *p-summable in the direction θ* if it is an asymptotic expansion of some function f_S holomorphic in a sector S with bisectrix $\arg t = \theta$ and with angle $> \pi/p$.

REMARK 3.49. If a series is of Gevrey type of order $s = 1 + 1/p$ then its Borel transforms $\mathcal{B}^l_{SN}$ or $\mathcal{B}^l_S$ define convergent series.

The transform $\mathcal{B}^l_{SN}$ is used in study of the saddle–node singularities from the class $\mathcal{E}_{p,\lambda}$ and the transform $\mathcal{B}^l_S$ is used in the study of the saddle singularities from the class $\mathcal{B}_{m,n,p,\lambda}$. The sectorial normalizing diffeomorphisms, which are used in the proofs of the Ecalle–Voronin and Martinet–Ramis theorems, have asymptotic expansion in the form of Gevrey series of order $s = 1 + 1/p$; moreover, they turn out p-summable in sectors S_j and T_j respectively (appearing in the proofs). The Gevrey series were used in the works of J. Ecalle [28,29] and J. Martinet and J.-P. Ramis [54,55], see also [53].

Recall that the Martinet–Ramis modulus of a saddle–node singularity from the class $\mathcal{E}_{p,\lambda}$ is a class $[\phi]$ of collections $(\phi_1, \dots, \phi_{2p})$ of germs of holomorphic maps such that $\phi_1(h) = a_1 + h$, $\phi_2(h) = h + a_{2,2}h^2 + a_{2,3}h^3 + \cdots$, $\phi_3(h) = a_3 + h, \dots \phi_{2p-1}(h) = a_{p-1} + h$, $\phi_{2p}(h) = \mathrm{e}^{-2\pi \mathrm{i}\lambda} h + a_{2p}h^2 + \cdots$, and the equivalence relation is defined by means of simultaneous mutual conjugation of the maps ϕ_j by means of a rescaling $h \to Ch$.

Let us pass to the logarithmic chart t, such that $h = \mathrm{e}^{2\pi \mathrm{i} t}$. Then the maps ϕ_j become maps $\Phi_j(t)$ expanded into Fourier series:

$$\Phi_1(t) = t + \sum_{l=-\infty}^{-1} b_{1,l} \mathrm{e}^{2\pi \mathrm{i} l t}, \qquad \Phi_2(t) = t + \sum_{l=1}^{\infty} b_{2,l} \mathrm{e}^{2\pi \mathrm{i} l t},$$

$$\vdots$$

$$\Phi_{2p}(t) = t - 2\pi \mathrm{i}\lambda + \sum_{l=1}^{\infty} b_{2p,l} \mathrm{e}^{2\pi \mathrm{i} l t},$$

where $b_{j,l} = (-a_i)^{-l}/(-l)$, $l = -1, -2, \dots$, for odd j are defined by $b_{j,-1} = -a_1$. In other words, the Martinet–Ramis moduli can be defined by the collection of the coefficients $b_{j,l}$, where $p \in \{1, \dots, 2p\}$ and $l \in \mathbb{N} \cup \{-1\}$.

P. Elizarov considered vector fields of the form

$$V_{p,\lambda} + \varepsilon \cdot \left(y \sum_{l=-1}^{\infty} y^l f_l(x) \right) \partial_y,$$

where $V_{p,\lambda}$ is the formal normal form vector field, f_l are holomorphic germs and ε is a small parameter. By Lemma 3.36 we can assume that $f_0(x) \equiv 0$ and that the other germs f_j have high order zero at $x = 0$. The following result an be regarded as calculation of the tangent to the moduli map.

THEOREM 3.50. (See [30].) *We have*

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon} b_{j,l}|_{\varepsilon=0} = \bigl(\operatorname{sign}(l) \mathrm{e}^{-2\pi j\lambda l i/p} l^{\lambda l/p-1}/p\bigr) \cdot (\mathcal{B}^l_{SN} f_l)\bigl(\mathrm{e}^{-(2j+1)\pi \mathrm{i}/p} (l/p)^{1/p}\bigr).$$

EXAMPLE 3.51. As an application of this result we consider the following germ

$$V = V_{p,\lambda} + x^k y^{q+1} \partial_y,$$

where $k > p$ and $q \in \mathbb{N} \cup \{-1\}$ are such that $(k + q\lambda)/p$ is not a negative integer. Then the series normalizing it to the formal orbital normal form is divergent. Moreover, two such germs with different exponents q are not analytically equivalent.

IDEA OF THE PROOF. We do not prove the Elizarov theorem, but we can say few words about the proof. By Theorem 3.45 the Martinet–Ramis modulus for the vector field $V \in \mathcal{E}_{p,\lambda}$ coincides with the Ecalle–Voronin of the monodromy diffeomorphism $\Delta \in \mathcal{A}_{p,\alpha}$. The holonomy map Δ can be calculated modulo $\mathrm{O}(\varepsilon^2)$ by integration of suitable equation in variations. We get $\Delta = \Delta_0 + \varepsilon R$ where Δ_0 is the time 1 phase flow map g^1_w and R is expressed via the series $y \sum y^l f_l(x)$. Recall that the conjugating map from the sectorial normalization theorem (Theorem 3.29) in the t_j-chart was defined by the formula $\tilde{H}_j(t_j) = t_j + \varepsilon \sum_m \tilde{R} \circ \tilde{\Delta}^m$, where $\tilde{\Delta}(t_j) = t_j + 1 + \mathrm{O}(\varepsilon)$. So, it is enough to compute the sums $\sum_m \tilde{R}(t_j + m)$ or rather differences between such sums for pairs of consecutive j's. The result is the above Elizarov's formula. □

Elizarov calculated also the tangent to the moduli map in the case of resonant saddle. Recall that here the modulus associated to a germ of vector field V from the class $\mathcal{B}_{m,n,p,\lambda}$ is the Ecalle–Voronin modulus of the holonomy map Δ associated with a loop in one of the separatrices. This modulus, rewritten in the logarithmic chart $t = \log \vartheta$ is an equivalence class of collection of $2p$ functions

$$\Phi_j(t) = t - \pi \mathrm{i}\lambda/np + \sum_{l=1}^{\infty} b_{j,l} \mathrm{e}^{2\pi \mathrm{i} l t}, \quad j \text{ odd},$$

$$\Phi_j(t) = t - \pi \mathrm{i}\lambda/np + \sum_{l=-\infty}^{-1} b_{j,l} \mathrm{e}^{2\pi \mathrm{i} l t}, \quad j \text{ even}.$$

Elizarov considers following germs

$$V = V_0 - \varepsilon x \frac{u^p}{1+\lambda u^p} P(x,y)\partial_x,$$

where V_0 is in the formal orbital normal form, defined in the previous subsection, $u = x^m y^n$ and $P = \sum c_{k,s} x^k y^s = \sum_l f_l(\tilde{x}) z^l$ and $\tilde{x} = xz^n$, $y = z^m$ and $f_l(\tilde{x}) = \sum_{ms-nk=l} c_{k,s}\tilde{x}^k$. The next theorem is proved in the same way as Theorem 3.50.

THEOREM 3.52. (See [30].) *We have*

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon} b_{j,l}|_{\varepsilon=0} = \alpha_{j,l} \cdot (\mathcal{B}_S^l f_l)\big(\mathrm{e}^{-(2j+1)\pi\mathrm{i}/(pm)}(l/pm^2)^{1/pm}\big)$$

where $\alpha_{j,l} \neq 0$ *are some concrete constants.*

We promised to calculate explicitly the Martinet–Ramis moduli in some situations. The following example is a continuation of Example 2.28 from Subsection 2.2.

EXAMPLE 3.53. Consider of the system

$$\dot{x} = x^{p+1}, \qquad \dot{y} = -y(p + ax^p) - x^{p+1}\varphi(x),$$

where $\varphi(x)$ is a germ of analytic function and $a \in \mathbb{C}$. Of course, it is a saddle–node singularity with the first integral

$$H = yx^a \mathrm{e}^{-1/x^p} + H_1(x)$$

where $H_1(x) = \int_0^x s^a \mathrm{e}^{-1/s^p}\varphi(s)\,\mathrm{d}s = \int f$ is the function defined in Example 2.28. Recall that the function $H_1(x)$ is well defined only in some sectors which contain one sector of fall of the function f, where $\operatorname{Re} 1/x^p > 0$ (and is a sector of jump for the foliation), and do not contain whole sectors of jump of f, where $\operatorname{Re} 1/x^p < 0$. These sectors are equal $S_1' \cap S_{2p}'$, where $H = x^a \mathrm{e}^{-1/x^p}(y + \chi_1(x))$, $S_3' \cup S_4'$, where $H = x^a \mathrm{e}^{-1/x^p}(y + \chi_3(x)) + A_0$, etc. The functions $\chi_j(x)$ are analytic in the sectors and the constants A_j are given by integration of $x^a \mathrm{e}^{-1/x^p}\varphi(x)\,\mathrm{d}x$ along so-called *asymptotic cycles* σ_j which begin and end at the origin and surround exactly one sector of jump (like at Fig. 1 in Section 2).

It follows that the Martinet–Ramis modulus is the following

$$\phi = (\mathrm{id} + A_0, \mathrm{id}, \mathrm{id} + A_1, \mathrm{id}, \ldots, \mathrm{id} + A_{p-1}, \mathrm{e}^{-2\pi\mathrm{i}\lambda}\,\mathrm{id}).$$

Consider saddle–node singularities with *analytic center manifold*. By Lemma 3.36 we can write them in the following analytic form

$$\begin{aligned} V &= V_0 + y^2 g_2(x,y)\partial_y = V_0 + RY, \\ V_0 &= x^{p+1}\partial_x - y(1 + \lambda x^p)\partial_y, \end{aligned} \tag{3.16}$$

where $R = yg_2(x, y)$ and $Y = y\partial_y$. So the center manifold is $x = 0$. Note that the vector fields V_0 and Y commute, $[V_0, Y] = 0$. L. Teyssier [80] noticed that one can try to conjugate V with V_0 by means of a local diffeomorphism of the form

$$G = g_Y^{F(x,y)}$$

where $\{g_T^t\}$ is the flow generated by the vector field Y: $G(x, y) = (x, \mathrm{e}^{F(x,y)}y)$. Rather elementary calculations, which use the equivalence of the equation $G^*U = W$ to $U \circ G = \frac{\partial G}{\partial W}$, give the following formula.

LEMMA 3.54. *The condition $G^*V_0 = V$ is equivalent to the equation*

$$\frac{\partial F}{\partial V} = -R.$$

A natural way to solve the equation $V(F) = -R$ is to rewrite it as $\dot{f}(t) = -r(t)$, when restricted to a leaf L of the foliation $\mathcal{F}$ defined by the vector field V. On the leaf L the 1-form $\mathrm{d}t = \tau = \mathrm{d}x/x^{p+1}$ is the 'time' form and we can express the solution in the form

$$F(x, y) = \int_{\gamma(x,y)} (-R)\tau$$

where $\gamma(x, y)$ is a path in the leaf $L(x, y)$ which connects the origin $x = y = 0$ with the point (x, y). There arises the problem of correctness of this definition.

Let us numerate the leaves of the foliation $\mathcal{F}$ by a value h of the first integral $yx^{-\lambda}\mathrm{e}^{1/px^p}$ (of V_0) restricted to a transverse line $x = x_*$, $L = L_h$. Since the vector field V has analytic center manifold, the function $(y|_{L_h})(x)$ on a fixed leaf L_h should tend to zero as $x \to 0$ within a sector of fall. Let $\gamma_j^\infty(h)$ be the lifts to L_h of the loops σ_j in the x-plane which begin and end at the origin in adjacent sectors of fall and surround exactly one sector of jump (like in Fig. 1 in Section 2); they are called the *asymptotic cycles* (see [79,80]). The quantities

$$\chi_j(h) = \int_{\gamma_j^\infty(h)} (-R)\tau$$

are the obstacles to the single validity of the function F.

But in suitable sectors which contain just one sector of fall we can define corresponding functions $F_j(x, y) = \int_{\gamma_j(x,y)} (-R)\tau$, where $\gamma_j(x, y)$ are paths in $L(x, y)$ which begin at the origin in the j-th sector of fall and end at the point (x, y). We have $F_{j+1} - F_j = \chi_j$. These functions define corresponding conjugating sectorial diffeomorphisms $H_j = g_Y^{F_j}$ and the functional cochain $\Phi_j = H_{j+1} \circ H_j^{-1} = (x, y\mathrm{e}^{\chi_j(h)}) = (x, h\mathrm{e}^{\chi_j(h)}\mathrm{e}^{-t(x)})$.

We can generalize the above to the case of resonant saddle, i.e. for $V = V_0 + RY$, where $R = yg(x, y)$ and $Y = y\partial_y$ are as above and

$$V_0 = -\frac{m}{n}x\big(1 + (\lambda - 1)u^p\big)\partial_x + y(1 + \lambda u^p)\partial_u, \quad u = x^n y^m. \tag{3.17}$$

Here also one tries changes of the form $G = g_Y^{F(x,y)}$ and arrives to the functions $\chi_j(h)$ defined in the same way.

Let us summarize this in the following theorem of L. Teyssier. (In his work [80] he uses a version of the Martinet–Ramis moduli when the germs ϕ_j are such that $\phi'_{2j}(0) = \mathrm{e}^{2\pi\mathrm{i}\lambda/p}$, but it is a subject to different choices of first integrals in the extended sectors T_j.)

THEOREM 3.55. (See [80].) *For a saddle–node singularity with analytic center manifold the Martinet–Ramis modulus equals*

$$(\mathrm{id}, h\mathrm{e}^{\chi_1(h)}, \mathrm{id}, h\mathrm{e}^{\chi_2(h)}, \mathrm{id}, \mathrm{e}^{-2\pi\mathrm{i}\lambda} h\mathrm{e}^{\chi_p(h)}).$$

An analogous formula holds for functional moduli for resonant saddle singularity from Theorem 3.44.

We finish this subsection by description of some recent results (due to S. Voronin, A. Grintchy, Yu. Meshcheryakova and L. Teyssier) about classification of saddle–node and resonant saddle singularities with respect to conjugation by means of local diffeomorphisms, but without change of time.

PROPOSITION 3.56. (See [60,38].) *Any saddle–node singularity whose formal orbital normal form is like V_0 in* (3.16) *is formally equivalent to*

$$P(x)V_0,$$

where $P(x)$, $P(0) \neq 0$, is a polynomial of degree at most p. Two such vector fields with polynomials P and P' are equivalent if $P'(x) = P(\mathrm{e}^{2\pi\mathrm{i}k/p}x)$ for some integer k.

Any resonant saddle singularity with formal orbital normal form like V_0 in (3.17) *is formally equivalent to*

$$P(u)V_0,$$

where $P(u)$, $u = x^n y^m$,is a polynomial of degree at most p.

PROOF. Consider the saddle–node case. Of course, we can assume that the vector field is of the form $Q(x,y)V_0$ where Q is a series with non-zero constant term. We try to reduce Q by means of diffeomorphisms which preserve the foliation $\mathcal{F}_0$ defined by V_0 and which are close to identity. They are of the form $G = g_{V_0}^{F(x,y)}$, i.e. the phase flow maps after varying time $F(x,y)$. An analogue of Lemma 3.54 says that $G^*(QV_0) = Q'V_0$, where Q' satisfies the equation

$$V_0(F) = \frac{1}{Q} - \frac{1}{Q'}.$$

Since $V_0(F) = x^{p+1}F_x - (1+\lambda x^p)yF_y$, it is easy to see that we can firstly reduce from $\frac{1}{Q}$ all terms divisible by y and next all terms divisible by x^{p+1}. From this the result easily follows.

In the resonant saddle case analogously we firstly reduce all terms from $\frac{1}{Q}$ different from a power of u and next use the fact that $V(R \circ u) = u^{p+1}\frac{\mathrm{d}R}{\mathrm{d}u}$. □

Let us describe the moduli, which generalize the Martinet–Ramis moduli for saddle–node singularities for fixed the polynomial $P(x)$ from the last proposition. Denote by $\mathcal{E}_{p,\lambda,P}$ the space of saddle–node germs with such formal normal form.

We consider collections $(\phi; \psi) = (\phi_1, \ldots, \phi_{2p}; \psi_1, \ldots, \psi_p)$ where $\phi = (\phi_1, \ldots, \phi_{2p})$ is the collection appearing in Definition 3.39 of the Martinet–Ramis moduli and $\psi_j(h)$ are germ of holomorphic functions in $(\mathbb{C}, 0)$ such that $\psi_j(0) = 0$.

DEFINITION 3.57. Two such collections $(\phi; \psi) = (\phi_1, \ldots, \phi_{2p}; \psi_1, \ldots, \psi_p)$ and $(\phi'; \psi') = (\phi'_1, \ldots, \phi'_{2p}; \psi'_1, \ldots, \psi'_p)$ are called *equivalent* iff ϕ_j and ϕ'_j are simultaneously conjugated by a linear transformation, $\phi_j \circ C = C\phi'_j$, and altogether we have $\psi_j \circ C = \psi'_j$.

The space of equivalence classes $[\phi; \psi]$ of such a collections is the *moduli space* denoted by $\mathcal{N}_{p,\lambda,P}$.

THEOREM 3.58. (See [60,79].) *There exists a map $W \to \varepsilon_W$ from $\mathcal{E}_{p,\lambda,P}$ to $\mathcal{N}_{p,\lambda,P}$ with the following properties*:

- *it sends analytically equivalent germs of vector fields to the same point* (*invariance*);
- *if $\varepsilon_W = \varepsilon_{W'}$ then W and W' are analytically equivalent* (*equimodality*);
- *for any $\varepsilon \in \mathcal{N}_{p,\lambda,P}$ there exists $W \in \mathcal{E}_{p,\lambda,P}$ such that $\varepsilon = \varepsilon_W$* (*realization*).

IDEA OF THE PROOF. We can assume that the vector field is of the form $W = QV$, where V is like in the thesis of Lemma 3.36, i.e. with $\dot{x} = x^{p+1}$. We try to reduce the germ QV to the germ $P(x)V$ using conjugation by means of the map $G = g_V^F$. Recall that this leads to the equation $V(F_j) = \frac{1}{Q} - \frac{1}{P}$. We can solve this equation in the extended sectors T_j. The obstacles to a solution in a whole neighborhood of the origin are given by the integrals

$$\psi_j(h) = \int_{\gamma_j^\infty} \left(\frac{1}{Q} - \frac{1}{P}\right) \frac{\mathrm{d}x}{Qx^{p+1}}$$

along the asymptotic cycles γ_j^∞ in the leaves L_h. The functions ψ_j constitute part of the modulus $(\phi; \psi)$.

By the sectorial normalization theorem (Theorem 3.37) we can reduce the vector field V in extended sectors T_j to V_0 and the obstructions to a univalent reduction form the collection ϕ (the Martinet–Ramis modulus), the other part of (ϕ, ψ).

We omit he other details of the proof. □

Finally we note that there exists a generalization of the latter theorem to the case of resonant saddle singularities. For details we refer the reader to the papers of A. Grintchy and S. Voronin [38] and L. Teyssier [79,80]. Besides the collection of $2p$ germs ϕ_i of local diffeomorphisms, defined in Theorem 3.44 (via Theorem 3.33) we have also collection of p germs of functions ψ_j.

3.7. *Linearization*

Now we pass to the non-resonant saddles. Their one-dimensional equivalents are the germs of non-resonant analytic diffeomorphisms f of $(\mathbb{C}, 0)$ of the form

$$z \to \mathrm{e}^{2\pi \mathrm{i}\alpha} z + \mathrm{O}(z^2),$$

where $\alpha \notin \mathbb{Q}$, $0 < \alpha < 1$. The Poincaré–Dulac theorem for diffeomorphisms says that any such f is formally linearizable (see Theorem 3.22); there exists a formal power series $h(z) \sim z + h_2 z^2 + \cdots$ such that $h^{-1} \circ f \circ h \sim \lambda z$, $\lambda = \mathrm{e}^{2\pi \mathrm{i}\alpha}$. The problem is under which assumptions f is analytically linearizable, i.e. when the series defining h is convergent.

The positive or negative answer to this question depends on the way how quickly the number α can be approximated by rational numbers. If α is slowly approximated by rationals then any such diffeomorphism is analytically linearizable. If α is quickly approximated by rationals then there should exist diffeomorphisms f for which the series h is divergent.

Let $\alpha = 1/a_1 + 1/a_2 + \cdots$ be the continued fraction expansion of the number α and let $1/a_1 + 1/a_2 + \cdots + 1/a_n = \frac{p_n}{q_n}$ be the successive rational approximations of α.

DEFINITION 3.59. We say that the number α satisfies the *Briuno condition* if

$$\sum \frac{\ln q_{n+1}}{q_n} < \infty.$$

The next theorem is the fundamental result of this section. Its first part was firstly obtained by A. Briuno, but the proof we present is due to C. Yoccoz. The second part was obtained by C. Yoccoz.

THEOREM 3.60. (See [16,87].) *If the number α satisfies the Briuno condition then any analytic diffeomorphism f is analytically linearizable and if α does not satisfy the Briuno condition then there exists an analytic diffeomorphism $f = \mathrm{e}^{2\pi \mathrm{i}\alpha} z + \cdots$ which is not analytically linearizable.*

REMARK 3.61. We should mention some previous results in this field. C. Siegel [74] proved that analyticity of the conjugating diffeomorphism holds when there exist two constants C, μ, such that for any integers p, q we have $|\alpha - p/q| > C|q|^{-\mu}$. If $\mu > 2$ then the set of those α, for which there exists a constant C with this property, is a set of full Lebesque measure.

A. Briuno [16] and H. Cremer [25] noticed that the Briuno condition is close to an optimal condition for convergence. They proved that if $\limsup \frac{\ln q_{n+1}}{q_n} = \infty$ then there exists an analytic diffeomorphism f which is not analytically linearizable.

The proofs of these results are based on estimations. The main achievement of J.-C. Yoccoz was to give a geometrical proof of a theorem of Briuno and to show that the Briuno condition is also necessary for convergence.

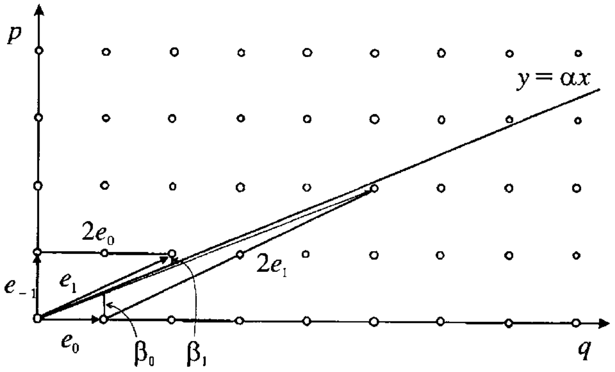

Fig. 8.

Before proving the main theorem of this section we recall some facts about *continued fractions*.

Let $0 < \alpha < 1$ be an irrational. Consider the real plane with coordinates x, y (see Fig. 8). We draw the line $y = \alpha x$. We distinguish the points with integer coordinates (q, p) in the first quadrant. They all, except $(0, 0)$, do not belong to our line. We consider the convex hulls of the sets of integer points of the quadrant, which lie at one side of our line (below and above respectively). (One can imagine the integer points as nails and our line as a thread with fixed one end at infinity; next one stretches the thread in the down direction and in the up direction.) The vertices (q, p) of the broken lines just constructed define the best approximations of the number α by rationals p/q.

We describe the construction of our broken lines in another way. Denote the basic vectors $e_{-1} = (0, 1)$, $e_0 = (1, 0)$. They lie in different sides of the line $y = \alpha x$. We shall construct a sequence of vectors $e_1, e_2, \ldots$ as follows. Let e_{n-1} and e_n be already constructed and lie in different sides of the line. We add the vector e_n to e_{n-1} as many times a_{n+1} as it is possible with the condition that the sum lies in the same side of the line as e_{n-1}.

In this way we obtain the sequence of natural numbers a_n and the sequence of integer vectors

$$e_1 = e_{-1} + a_1 e_0, \ldots, e_{n+1} = e_{n-1} + a_{n+1} e_n.$$

(Note that $a_1 = [1/\alpha]$, the integer part of $1/\alpha$.) The endpoints of the vectors $e_n = (q_n, p_n)$ are the vertices of the above two convex hulls.

We denote by β_n the 'distance' of the point e_n to the line $y = \alpha x$

$$\beta_n = (-1)^n (q_n \alpha - p_n).$$

From Fig. 8 it is seen that $\beta_{-1} = 1$, $\beta_0 = \alpha$ and $\beta_{n+1} = \beta_{n-1} - a_{n+1}\beta_n$, which implies that the ratios p_n/q_n form the best approximations to α, in the sense that $|\alpha - p_n/q_n| < |\alpha - p/q|$ for any p and any $q < q_n$. In fact, we have $\beta_n < |q\alpha - p| < \beta_{n-1}$ for $q_{n-1} < q < q_n$.

We define also the numbers $\alpha_n = \beta_n / \beta_{n-1}$. Thus $\alpha_0 = \alpha$. They lie between 0 and 1. We obtain $\alpha_{n-1}^{-1} = a_n + \alpha_n$. This means that $\alpha_0 = \{\alpha\}, \ldots, \alpha_{n+1} = \{\alpha_n^{-1}\}$ where $\{\cdot\}$ denotes the fractional part. Moreover, iterating the latter identity we recognize the continued fraction

$$\alpha = a_0 + \alpha_0 = a_0 + \frac{1}{a_1 + \alpha_1} = a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \alpha_2}} = \cdots.$$

Note also that

$$\beta_n = \alpha_0 \cdots \alpha_n.$$

We note also that the (oriented) area of the parallelogram with sides e_n, e_{n-1} is equal to $(-1)^n$. It implies $q_{n+1}\beta_n + q_n\beta_{n+1} = 1$, or

$$\beta_n(q_{n+1} + q_n\alpha_{n+1}) = 1.$$

From this one proves the following (see also [89])

LEMMA 3.62. *The following conditions are equivalent*:

- $\sum q_n^{-1} \ln q_{n+1} < \infty$;
- $\Phi(\alpha) \overset{df}{=} -\sum \beta_n \ln \alpha_{n+1} < \infty$.

3.7.1. *Proof of the analytic linearizability* (We follow [65].) Recall that we have to prove the analyticity of the conjugation series under assumption of the Briuno condition.

We begin with the following criterion of analytic linearizability.

LEMMA. *f is linearizable iff it is stable, i.e. iff for any neighborhood U of* 0 *there is a neighborhood V such that $f^n(V) \subset U$ for all $n \geqslant 0$.*

PROOF. If f is linearizable then it is stable because the linear map is stable.

Assume that f is stable and let V be such that $f^n(V) \subset U = \mathbf{D}$, $n \geqslant 0$. Then the family $f^n|_V$ is normal. Define $h_n = \frac{1}{n}\sum_{i=0}^{n-1} \lambda^{-i} f^i$. It is also normal family. We have $h_n \circ f = \lambda h_n + \frac{1}{n}\lambda(\lambda^{-n} f^n - 1)$.

Now it is enough to choose a convergent subsequence from $\{h_n\}$ and the limit conjugates f with λz. □

After rescaling the variable z we can assume that we are dealing with functions which are analytic diffeomorphisms of the unit disc $\mathbf{D} = \{|z| < 1\}$ into $\mathbb{C}$ with the fixed first term $e^{2\pi i\alpha} z$. We denote the space of such functions by $S(\alpha)$. Of course, we can (and shall) assume that $0 < \alpha < 1$.

The space $S(\alpha)$ has nice properties based on the following *Theorem of Koebé*:

If $f : (\mathbf{D}, 0) \to (\mathbb{C}, 0)$ is an univalent holomorphic function with $|f'(0)| = 1$ then

$$\bigl|f(z)\bigr| < |z|\bigl(1 - |z|\bigr)^{-2}, \qquad \bigl|f'(z)\bigr| < \bigl(1 + |z|\bigr)\bigl(1 - |z|\bigr)^{-3}.$$

The important corollary of the Koebé estimates is the following.

LEMMA. *The spaces $S(\alpha)$ are compact in the topology of almost uniform convergence. In other words, the family $S(\alpha)$ is normal.*

The authorship of next lemma belongs to A. Douady and E. Ghys.

LEMMA. *The set of those α, for which any $f \in S(\alpha)$ is linearizable, is invariant with respect to the action of the group* $\mathrm{SL}(2,\mathbb{Z}) : \alpha \to \frac{a\alpha+b}{c\alpha+d}$.

PROOF. The group $\mathrm{SL}(2,\mathbb{Z})$ is generated by transformations of the form $\alpha \to \alpha + 1$ and $\alpha \to -1/\alpha$. The invariance with respect to the first transformations is obvious.

Let $0 < \alpha < 1$. We shall associate with any $f \in S(\alpha)$ a map $g \in S(\beta)$, $\beta = -1/\alpha$. If l is a ray and $f(l)$ is its image, then we add a curve l' closing-up a triangle-like region Δ. We glue l with $f(l)$ by means of f and obtain a surface, which admits a holomorphic structure of the disc **D** (see Appendix 1 below). This equivalence is of the form $z \to z_1 = z^{1/\alpha} + \cdots$.

Denote by g the map of first return to Δ. It turns out to be holomorphic with respect to the complex structure on $\Delta/\sim$. Expressed in the chart $z_1 = \rho \mathrm{e}^{\mathrm{i}\theta}$ on $\Delta/\sim$ it takes the form

$$\mathrm{e}^{2\pi\mathrm{i}(j\alpha-1)/\alpha+\mathrm{i}\theta}\rho + \cdots = \mathrm{e}^{2\pi\mathrm{i}\beta} z_1 + \cdots,$$

where $j = j(z_1)$ is the moment of the first return. □

It is useful to pass to the chart, where the punctured disc $\mathbf{D}^*$ is replaced by its infinite covering; the upper half-plane $\mathbf{H} = \{\operatorname{Im}\zeta > 0\}$ with the covering map $\zeta \to z = \mathrm{e}^{2\pi\mathrm{i}\zeta}$.

The lift of the map f to **H** has the form

$$F(\zeta) = \zeta + \alpha + \sum a_n \mathrm{e}^{2\pi\mathrm{i}n\zeta},$$

i.e. it commutes with the translation id$+1$. Using the compactness of the space $S(\alpha)$ (or estimates for the coefficients a_n) it is possible to get the following uniform bound for the difference of F from the pure translation.

LEMMA. *There exists a constant C, not depending on α and F, such that the inequality*

$$\left|F(\zeta) - \zeta - \alpha\right| < \alpha/4$$

holds for

$$\operatorname{Im}\zeta > t(\alpha) \overset{df}{=} (2\pi)^{-1} \cdot \ln \alpha^{-1} + C.$$

The construction from the proof of the previous lemma can be implemented for maps on **H**. It is presented at Fig. 9. The line $l = \{\zeta = \mathrm{i}t, t > t(\alpha)\}$ is identified with $F(l)$. The domain $\tilde{\Delta}$ between l, $F(l)$ and the straight segment (joining $\mathrm{i}t(\alpha)$ with $F(\mathrm{i}t(\alpha))$) is replaced

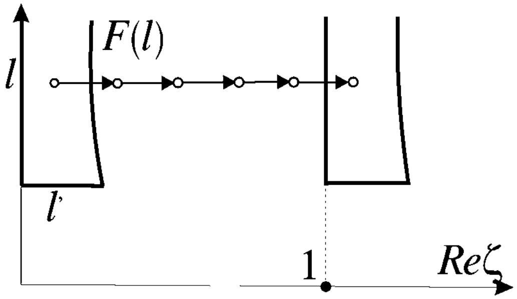

Fig. 9.

by the domain $\{0 \leqslant \operatorname{Re} \zeta_1 \leqslant 1, \operatorname{Im} \zeta_1 \geqslant 0\} \subset \mathbf{H}$: $\zeta_1 \approx \alpha^{-1}(\zeta - \mathrm{i}t(\alpha))$. The map $G \in S(\beta)$, $\beta = -1/\alpha$ is induced by the return map to $\tilde{\Delta}$ with the chart ζ_1.

Because we use the expansions of α into continuous fractions we prefer to get some map from $S(1/\alpha)$. This is done by conjugation of the map G with the map $\zeta = s + \mathrm{i}t \to -s + \mathrm{i}t$ which reverses the orientation. The new map will be denoted also by G.

Therefore we have the transformation from $S(\alpha)$ to $S(1/\alpha)$: $F \to G = G(F)$.

Note that if F is unstable, i.e. iterations of some points escape from the upper half-plane, then G is also unstable and the escape is quicker that for F. The following lemma provides a quantitative description of this.

LEMMA. *If a point* ζ *with* $\operatorname{Im} \zeta > t(\alpha)$ *escapes from* $\mathbf{H}$ *after* m *iterations of* F, *i.e.* $F^m(\zeta) \notin \mathbf{H}$ *and* $F^i(\zeta) \in \mathbf{H}$, $i < m$, *then there exists a point* ζ_1 *with* $\operatorname{Im} \zeta_1 > \alpha^{-1}(\operatorname{Im} \zeta - t(\alpha) - C_1)$ *which escapes from* $\mathbf{H}$ *after* $m_1 < m$ *iterations of* G. *Here* C_1 *is an universal constant such that* G *is well defined for* $\operatorname{Im} \zeta > t(\alpha) + C_1$.

Let us start to iterate the property of the latter lemma. Let the formulas

$$\alpha_0 = \alpha, \qquad \alpha_n^{-1} = a_{n+1} + \alpha_{n+1}$$

define the sequence of natural numbers a_n and $\alpha_n \in (0, 1)$. We put $F_0 = F$, $F_1 = G(F_0) - a_1 \in S(\alpha_1), \ldots, F_{n+1} = G(F_n) - a_n$

If the point ζ_1 (from the latter lemma) satisfies the inequality $\operatorname{Im} \zeta_1 > t(\alpha_1)$, which is equivalent to

$$\operatorname{Im} \zeta > t(\alpha_0) + \alpha_0 t(\alpha_1) + C_1, \tag{3.18}$$

then $F_1^{m_1}(\zeta_1) \notin \mathbf{H}$, $F_2^{m_2}(\zeta_2) \notin \mathbf{H}$ for some ζ_1, ζ_2 and $0 < m_2 < m_1 < m$.

At the n-th repeating of this procedure the inequality (3.18) should be replaced by $\operatorname{Im} \zeta > t(\alpha_0) + \alpha_0 t(\alpha_1) + \alpha_0 \alpha_1 t(\alpha_2) + \cdots + \alpha_0 \cdots \alpha_n t(\alpha_{n+1}) + C_1$. Because $t(\alpha) = -\ln \alpha/(2\pi) + C$, $\beta_n = \alpha_0 \cdots \alpha_n$ (see above), the latter finite series equals (up to constants) to the partial sum defining the series $\Phi(\alpha) = -\sum \beta_n \ln \alpha_{n+1}$ (defined in Proposition 3.62). By the Briuno condition this series is convergent.

We claim that the region $\operatorname{Im} \zeta > \sum \beta_n t(\alpha_{n+1}) + C_1$ is the region of stability of the map F. Assuming contrary, it should contain a point ζ_0 escaping from $\mathbf{H}$ after n_0 iterations

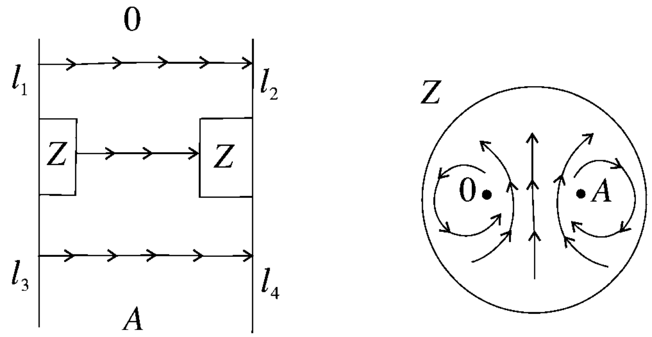

Fig. 10.

of $F = F_0$. This would imply existence of infinite sequence of points ζ_j escaping after n_j iterations of F_j. Moreover one should have infinite sequence of inequalities

$$0 < \cdots < n_2 < n_1 < n_0.$$

Of course, it is not possible.

3.7.2. *Proof of the non-linearizability* The idea of the proof of the second part of Theorem 3.60 is to construct a map from $S(\alpha)$ with a sequence of periodic orbits approaching the fixed point 0. By reversing and modifying the construction of Douady and Ghys one successively inserts fixed points near 0. In the next modification this fixed point becomes periodic and a new fixed point is inserted.

The reversing of the construction $F \to G(F)$, i.e. the transformation $G \to F(G)$, is presented at Fig. 10.

Let $G \in S(\beta)$, $0 < \beta < 1$, and let a be a positive integer. We put $\alpha = (\beta + a)^{-1}$ and let $\tilde{G} = G + a$.

We have the half-line $l_1 = \{\zeta = \mathrm{i}t, t > t_0\}$, its image $l_2 = \tilde{G}(l_1)$, the half-line $l_3 = \{\mathrm{i}t, t < t_0\}$ and the half-line $l_4 = l_3 + [\tilde{G}(\mathrm{i}t_0) - \mathrm{i}t_0]$. These curves bound a domain Λ, close to a vertical strip. Identifying the sides of this non-straight strip, we would obtain a surface $\Lambda/\sim$ with a holomorphic structure of $\mathbb{C}^*$. Because we want to have a disc, we delete form $\Lambda/\sim$ a disc Z around $\mathrm{i}t_0$ of size O(1), like at Fig. 10. Thus $(\Lambda/\sim) \setminus Z$ is the same as a doubly punctured disc $\mathbf{D} \setminus \{0, A\}$: $\mathrm{i}\infty$ is sent to 0 and $-\mathrm{i}\infty$ is sent to a point A. The set Z is sent to the outside of $\mathbf{D}$. (Of course, $(\Lambda/\sim) \setminus Z$ can be next covered by $\mathbf{H}$).

Let us define the dynamics on $(\Lambda/\sim) \setminus Z$, as induced by the translation $\mathrm{id}+1$. Because G commutes with $\mathrm{id}+1$ and l_4 is a translation of l_3 we obtain a well defined map of the quotient $(\Lambda/\sim) \setminus Z$. We denote it by $F = F(G)$. It is easy to see that $F \in S(\alpha)$ and that F has two fixed points in $\mathbf{D}$: 0 and A (see Fig. 10). Therefore we have inserted a new fixed point.

Before exploring this construction we have to perform some estimates. We want to insert the fixed point A as close to 0 as possible. However there are some restrictions implied by the geometry of the closure of $(\Lambda/\sim) \setminus Z$. When we delete from it a disc containing 0 and A then we obtain a domain Λ_1 in form of an annulus.

There is a conformal invariant of annulus, the modulus equal to $m = \ln(R/r)$ (see the Definition 3.75 below).

The modulus of the ring Λ_1 is of order $-\ln|A|$. On the other hand, this modulus can be estimated from Fig. 10. The domain Z is of order $O(1)$ and the domain Λ is of order $O(a) = O(\alpha^{-1})$; (it is the width of Λ). This implies that the modulus of Λ_1 is of order $\ln\alpha$. The rigorous proof uses the estimate from the Theorem 3.76: $m \geqslant L^2/S$, where $S = \iint_{\Lambda-\Lambda_1}\rho$, $L = \inf\int_\gamma \rho$, where $\rho(\zeta) > 0$ is some function and γ's are paths joining the two components of the boundary of Λ_1. Yoccoz [87] uses $\rho(\zeta) = 1/|\zeta - \zeta_j|$ (in the ζ-plane).

This allows to get the estimate $|A| < \text{const}\cdot\alpha$. This estimate, expressed in terms of coordinates at the upper half-plane, says that we have the fixed point ζ_0 of F and satisfying

$$\operatorname{Im}\zeta_0 > t(\alpha) - C_2$$

where $t(\beta) = -(\ln\beta)/(2\pi) + C$ is the same as in the previous proof and C_2 is some universal constant.

Notice also that, if G has some periodic orbit then F also has a periodic orbit. We have the following

LEMMA. *Let* $0 < \beta < 1$, *a be a positive integer,* $\alpha = (\beta + a)^{-1}$ *and* $G \in S(\beta)$. *There exists* $F \in S(\alpha)$ *such that*:

- *F has fixed point ζ_0 with* $\operatorname{Im}\zeta_0 > t(\alpha) - C_2$.
- *If G has a periodic orbit with the rotation number p/q (i.e. $G^q(\zeta) = \zeta + p$) then F has a periodic orbit $\{F^i(\zeta')\}$ with the rotation number $(a + p/q)^{-1}$ and such that*

$$\min \operatorname{Im} F^j(\zeta') > \alpha \cdot \min \operatorname{Im} G^i(\zeta) + t(\alpha) - \text{const}.$$

Let α_n and a_n be the sequences defining the continued fraction expansion. For any natural m we construct series of maps $F_{m,m+1}, F_{m,m}, \ldots, F_{m,0}$ as follows.

$F_{m,m+1} = \zeta + \alpha_{m+1} \in S(\alpha_{m+1})$, $F_{m,m} = F(F_{m,m+1})$ (with $a = a_{m+1}$) and other maps are constructed in the same way: $F_{m,l} = F(F_{m,l+1})$. Thus $F_{m,0} \in S(\alpha)$.

Moreover, each $F_{m,0}$ has periodic orbits with rotation numbers equal to the reduct p_n/q_n of the continuous fraction. The imaginary parts of such orbit are estimated from below by $\sim \sum_{i=1}^n \beta_{i-1}|\ln\alpha_i|$. Because the Briuno condition fails the latter series tends to infinity.

Now we choose a convergent subsequence from the sequence $F_{m,0}$. Its limit is just the F we are looking for. It has infinite series of periodic orbits with arbitrary large imaginary part. These periodic orbits form an obstacle to the linearizability of F. □

We shall apply the theorems of Briuno and of Yoccoz to germs of analytic planar vector fields with singular points of saddle type without resonance

$$\dot{x} = \alpha x(1 + \cdots), \qquad \dot{y} = -y(1 + \cdots), \tag{3.19}$$

where α is irrational.

As in the resonant case one associates with the analytic separatrix $x = 0$ the monodromy map $\Delta : (\mathbb{C}, 0) \to (\mathbb{C}, 0)$, $\Delta(x) = e^{-2\pi i\alpha}x + \cdots$. Theorems 3.60 implies the following.

THEOREM 3.63. *If α satisfies the Briuno condition than any germ* (3.19) *is analytically orbitally linearizable.*

If α does not satisfy the Briuno condition then we cannot simply apply Theorem 3.60. We should have the realization theorem; any germ of non-resonant one-dimensional map is realized as a holonomy map of certain holomorphic foliation with saddle singularity. Such theorem was proved by R. Perez-Marco and C. Yoccoz [66] (see also [31]).

THEOREM 3.64. *Let α be irrational. The correspondence*:

germ of vector field (3.19) $\rightarrow$ *the germ Δ of its monodromy*

is surjective. This implies that if α does not satisfy the Briuno condition, then there exists a germ (3.19) *of vector field which is not analytically linearizable.*

We do not present the proof of this result. It relies on gluing together certain domains with standard foliations and application the theory of almost complex structures to get a holomorphic foliation.

3.8. *Appendix 1. Complex structures and almost complex structures*

Consider the following situation. Let M^n be a n-dimensional complex manifold. Let us treat it as a $2n$-dimensional real manifold ${}^{\mathbb{R}}M^{2n}$. Assume now that the complex atlas on M is replaced by a C^1-smooth atlas on ${}^{\mathbb{R}}M^{2n}$. It turns out that the complex structure from M is not completely lost on ${}^{\mathbb{R}}M^{2n}$. There remains its trace called the almost complex structure.

DEFINITION 3.65. An *almost complex structure* on a real manifold M is a field $J = \{J_x\}$ of endomorphisms of the tangent spaces T_xM satisfying the identity

$$J_x^2 + I = 0.$$

In other words, it is a field of splittings of the complexifications of tangent spaces into eigenspaces of J_x with eigenvalues $\mathrm{i} = \sqrt{-1}$ and $-\mathrm{i}$

$${}^{\mathbb{C}}T_xM = T_xM \otimes \mathbb{C} = T_x^{1,0} \oplus T_x^{0,1}$$

of equal (complex) dimension n.

The standard complex structure on a complex manifold N, with local complex coordinates $z_j = x_j + \mathrm{i}y_j$, induces the almost complex structure by the formulas $J\partial_{x_j} = \partial_{y_j}$, $J\partial_{y_j} = -\partial_{x_j}$.

DEFINITION 3.66. An almost complex structure J is called *integrable* if locally it is an image of complex structure by means of a C^1-mapping. It means that in neighborhood of any point on M there exists a local system of C^1-coordinates x_j, y_j such that the above formulas hold.

If M is a real analytic $2n$-dimensional manifold and ${}^{\mathbb{C}}M$ is its local complexification (a complex $2n$-dimensional manifold containing M as its real part) then the integrability of the almost complex structure means simultaneous integrability of the two distributions $T^{1,0} = \bigcup T_x^{1,0}({}^{\mathbb{C}}M)$ and $T^{0,1}$. The local leaves of the corresponding foliations are $\{x_1 + \mathrm{i}y_1 = c_1, \dots, x_n + \mathrm{i}y_n = c_n\}$ and $\{x_1 - \mathrm{i}y_1 = d_1, \dots, x_n - \mathrm{i}y_n = d_n\}$, $x_j, y_j, c_j, d_j \in \mathbb{C}$.

The splitting of the complexifications of the tangent spaces induces analogous splitting of the complexifications of the cotangent spaces into forms of the type $(1,0)$ and of the type $(0,1)$,

$$ {}^{\mathbb{C}}T^*M = {}^{\mathbb{C}}\mathcal{E}^1 = \mathcal{E}^{1,0} \oplus \mathcal{E}^{0,1}; $$

ω is of the type $(1,0)$ iff it vanishes at $T^{0,1}$. This induces splitting of all differential k-forms (with complex coefficients) into forms of the type (p,q).

As we know from Frobenius theorem (see [43]) the distributions $T^{1,0}$ and $T^{0,1}$ (of vectors of the type $(1,0)$ and $(0,1)$ respectively) are integrable iff they are involutive. This means that the commutator of any two vector fields from $T^{1,0}$ (respectively from $T^{0,1}$) is a vector field from $T^{1,0}$ (respectively from $T^{0,1}$). This condition can be written in the following compact form.

DEFINITION 3.67. The *torsion* of the almost complex structure J is the following bilinear form on the space of vector fields on M

$$ N(X,Y) = 2\big\{[JX, JY] - [X,Y] - J[X, JY] - J[JX, Y]\big\}. $$

Vanishing of the torsion is equivalent to the fact that the derivative of a form ω of the type $(1,0)$ does not have component of the type $(0,2)$. Note that, if $JX = \epsilon X$ and $JY = \epsilon Y$, $\epsilon = \pm\mathrm{i}$, then $N(X,Y) = -4\{[X,Y] + \epsilon \mathrm{i} J[X,Y]\}$.

The following result is known as the *Newlander–Nirenberg theorem*. In the case of real analytic manifold M this result follows from the above remarks and the Frobenius theorem. A. Newlander and L. Nirenberg proved it in the finitely smooth case.

THEOREM 3.68. (See [64].) *An almost complex structure is integrable iff its torsion vanishes.*

Now we pass to the 1-dimensional case. Here the problem of integrability of almost complex structures is treated differently. Assume that we are in a 2-dimensional plane (local chart) which we identify with the complex plane $\mathbb{C}$. Here the splitting of ${}^{\mathbb{C}}T^*\mathbb{C}$ can be defined by means of one 1-form

$$ \omega = \mathrm{d}z + \mu\, \mathrm{d}\bar{z} $$

where $\mu = \mu(z, \bar{z})$ is a function. We have $\mathcal{E}^{1,0} = \mathbb{C}\,\omega$ and the other space $\mathcal{E}^{0,1}$ is its conjugate.

The function μ is not defined uniquely. Notice that, when we replace the complex variable z by $w = \phi(z)$ (ϕ holomorphic), then the analogous 1-form $\tilde{\omega} = \mathrm{d}w + \tilde{\mu}\,\mathrm{d}\bar{w}$ takes the form

$$\phi_z'\,\mathrm{d}z + \tilde{\mu}\bar{\phi_z'}\,\mathrm{d}\bar{z} = \phi_z'\big[\mathrm{d}z + \tilde{\mu}\cdot(\bar{\phi_z'}/\phi_z')\cdot\mathrm{d}\bar{z}\big]. \tag{3.20}$$

This rule of transformation of μ suggests the following definition.

DEFINITION 3.69. The quantity

$$\mu\cdot(\mathrm{d}\bar{z}/\mathrm{d}z)$$

is called the *Beltrami differential* defining the almost complex structure. In particular, $|\mu|$ is a well defined function.

The integrability of the almost complex structure, defined by the Beltrami differential, means existence of a differentiable complex function $\phi = \phi(z, \bar{z})$ which is a homeomorphism and such that the almost complex structure is defined by $\phi^*\,\mathrm{d}u = \mathrm{d}\phi = \phi_z\,\mathrm{d}z + \phi_{\bar{z}}\,\mathrm{d}\bar{z}$, i.e. the following *Beltrami equation*

$$\phi_{\bar{z}} = \mu\phi_z$$

holds. The Beltrami equation is a partial differential equation and is solved in a suitable Sobolev space. The ϕ's satisfying the Beltrami equation are called the *quasi-conformal maps* and $\mu = \mu_\phi$ is called the *modulus* of ϕ.

(Note that the torsion of any almost complex structure in $\mathbb{C}$ vanishes. It is because $\bigwedge^2 \mathcal{E}^1 \otimes \mathbb{C} = \mathcal{E}^{1,0} \wedge \mathcal{E}^{0,1}$ is one dimensional and contains only 2-forms of the type $(1, 1)$. Therefore here we have different kind of problems than in multi-dimensional case. In particular, one condition of integrability would be the preservation of the orientation by the map ϕ; it is equivalent to the property $|\mu| < 1$.)

The next theorem has many authors (L. Ahlfors, B. Bojarski, L. Bers).

THEOREM 3.70. (See [1].) *If μ is continuous and satisfies the estimate*

$$\big|\mu(x)\big| \leqslant k < 1$$

then the Beltrami equation has a solution and the almost complex structure defined by $\mu\,\mathrm{d}\bar{z}/\mathrm{d}z$ is integrable.

REMARK 3.71. If g is a conformal (i.e. analytic) mapping then $\phi \circ g$ is quasi-conformal with the modulus $\mu_{\phi\circ g} = \mu_\phi \circ g \cdot (\bar{g'}/g')$ and $g \circ \phi$ is quasi-conformal with $\mu_{g\circ\phi} = \mu_\phi$ (see (3.20)). This means that the Beltrami equation has many solutions.

If $\|\mu_\phi\|_\infty = k < 1$ then the map ϕ transforms infinitesimally small sphere around any z_0 to an infinitesimally small ellipse with the ratio of lengths of the semi-axes (longer to shorter) $K(z_0)$. We have $\sup K(z_0) = (1+k)/(1-k)$.

This implies that, if $\mu_\phi = \mu_\psi$ then the map $\phi \circ \psi^{-1}$ is conformal; ψ^{-1} maps circles to ellipses which are sent again to circles by ϕ.

Consider now the following situation. Let $f : \mathbb{C}^* = \mathbb{C} \setminus 0 \to S$ be a smooth diffeomorphism onto a Riemann surface S. Define $\mu = f'_{\bar{z}}/f'_z$. Assume that $\mu(z)$ can be continuously prolonged to $\bar{\mathbb{C}} = \mathbb{C} \cup \infty$ with $\mu(0) = \mu(\infty) = 0$.

PROPOSITION 3.72. *In such a case there exists a conformal mapping* $g : \mathbb{C}^* \to S$. *This means that* S *has conformal type of* $\mathbb{C}^*$ (*not of an annulus or of a punctured disc*).

PROOF. We prolong μ to $\bar{\mathbb{C}}$ and integrate the corresponding Beltrami equation in the Riemann sphere. Using an eventual composition with a Möbius automorphism we can assume that the solution $u : \bar{\mathbb{C}} \to \bar{\mathbb{C}}$ is a homeomorphism such that $u(0) = 0$, $u(\infty) = \infty$.

We have $\mu_u = \mu_f$ in $\mathbb{C}^*$ and the map $u \circ f^{-1} : S \to \mathbb{C}^*$ is conformal (see the above remark). □

DEFINITION 3.73. If $Q \subset \mathbb{C}$ is a (curved) quadrangle, considered together with a pair of arcs on its boundary (b-arcs) then it can be transformed conformally onto a rectangle (with sides a, b), such that the b-arcs are sent to the vertical sides. The ratio of the lengths of sides is called the *modulus* of Q (see [1])

$$m(Q) = a/b.$$

If $P \subset \mathbb{C}$ is a domain, which can be conformally transformed to an annulus $\{r < |z| < R\}$, then we define its *modulus* as

$$m(P) = \ln(R/r).$$

$m(Q)$ is an invariant of conformal transformations; (by applying the Schwarz lemma one easily shows that two rectangles are conformally equivalent iff their moduli are the same).

The condition of quasi-conformality (for a map ϕ) says that $m(Q') < Km(Q)$ for any quadrangle Q transformed to a quadrangle Q'. Here $K = (1+k)/(1-k)$ is the constant from Remark 3.73. It means that K measures the distortion of small squares.

Note that the map $\ln z$ transforms the standard annulus, cut along a radius, into the rectangle with the sides $\ln R - \ln r$ and 2π. Thus, up to a constant, the modulus of a ring is the same as the modulus of corresponding quadrangle.

There is another definition of the modulus of quadrangle which does not make use of conformal mapping to rectangle.

THEOREM 3.74. (See [1].) *The modulus* $m(Q)$ *of a rectangle equals* $\sup_\rho L^2(\rho)/A(\rho)$, *where* ρ *are square integrable non-negative functions,* $A(\rho) = \iint_Q \rho^2 \, \mathrm{d}x \, \mathrm{d}y$ *and* $L(\rho) = \inf \int_\gamma \rho |\mathrm{d}z|$ *and* γ *are paths joining the* b*-arcs.*

3.9. *Appendix 2. Proof of the Hukuhara–Kimura–Matuda theorem*

(We follow the book [40] and also [89].) We shall present the proof only in the case $p = 1$. Therefore we assume that $x^2\,\mathrm{d}y/\mathrm{d}x = g_0(x) + y(1+\lambda x) + y^2 g_2(x, y)$ where g_0, $y^2 g_2$ have zero at $x = y = 0$ of order $\geqslant 3$ (compare Lemma 3.36).

Let $S = \{-\pi/2+\alpha < \arg x < 3\pi/2-\alpha, |x| < \epsilon\}$ be a sector in the x-plane (see Fig. 11); the case of opposite sector is considered analogously. We seek a change $(x, y) \to (x, z)$ such that $x^2\,\mathrm{d}z/\mathrm{d}x = z(1 + \lambda z^2)$ in S.

The proof is divided into two parts: existence of analytic central manifold in S_1 and analyticity of $z(x, y)$.

Existence of the center manifold. We seek it in the form of a graph

$$y = u(x)\mathrm{e}^{-1/x}, \quad x \in S,$$

where $u(x)\mathrm{e}^{-1/x} = \mathrm{O}(x)$ in the sector. We obtain the following equation onto u

$$x^2 u' = F(x, u) \tag{3.21}$$

where $F = g_0\mathrm{e}^{1/x} + \lambda x u + u^2\mathrm{e}^{-1/x} g_2(x, u\mathrm{e}^{1/x})$. We seek the solution to (3.21) in the class of functions satisfying the estimate

$$|u| < K|x|\mathrm{e}^{\mathrm{Re}(1/x)} \tag{3.22}$$

for some constant K.

The right-hand side of (3.21) satisfies the estimates: $|F(x, u_1) - F(x, u_2)| < \delta|u_1 - u_2|$ and $|F| < (K_0 + \delta K)|x|\mathrm{e}^{\mathrm{Re}(1/x)}$ for some small δ and fixed K_0. The first (Lipschitz) condition will guarantee the uniqueness of the solution.

As in other similar problems, Eq. (3.21) is replaced by the integral equation

$$u(x) = \int_0^x F\bigl(s, u(s)\bigr)s^{-2}\,\mathrm{d}s,$$

which is a fixed point equation $u = T(u)$ for a non-linear operator T. We use the following *Leray–Schauder–Tikhonov fixed point theorem*:

Any continuous map of a compact and convex subset of a locally convex space into itself contains a fixed point.

In our case the set of u's satisfying (3.22) is convex and compact in the topology of almost uniform convergence. It remains to show that the operator T maps the set defined by (3.22) into itself.

The latter statement is proved by appropriate choosing the path γ of integration in the formula defining T. This path is presented at Fig. 11.

Let $s = r\mathrm{e}^{\mathrm{i}\theta}$. We have the straight segment γ_1 joining 0 with $x_0 = r_0\mathrm{e}^{\mathrm{i}\pi/2+2\eta}$, where $\eta > 0$ is a small constant and r_0 will be defined later. In the second part γ_2 we have we have either $r(\theta) = r_0\sqrt{\sin(\theta - \pi/2 - \eta)}$ or $r_0\sqrt{\sin(\pi/2 + 3\eta - \theta)}$, depending on whether $\arg x > \pi/2 + 2\eta$ or not. If the angle α (defining the sector S, see above) is greater than 4η

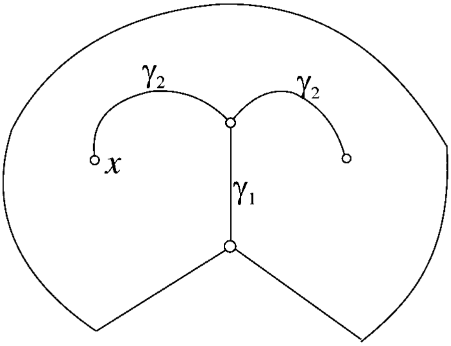

Fig. 11.

then $r_0 < r(\theta) < Mr_0$ (where $M = M(\eta)$). Now we chose r_0 such that Mr_0 is sufficiently small, $< \epsilon$.

One can show that for large K the quantity $|Fs^{-2}|$ is bounded by maximum of the absolute values of some derivatives of $K|s|\mathrm{e}^{\mathrm{Re}(1/s)}$ along $\gamma_{1,2}$ (see [40]). This gives $|T(u)| = |\int Fs^{-2}| \leqslant K|x|\mathrm{e}^{\mathrm{Re}(1/x)}$.

2. Now we can assume that $x^2\,\mathrm{d}y/\mathrm{d}x = y(1+\lambda x + yg_2)$ in S. We have to find the change $y \to z(x, y)$ giving the normal form $x^2 z' = z(1+\lambda x)$.

We represent y as a function of (x, z) : $y = z + \phi(x, z)$. The function ϕ satisfies the following partial differential equation $x^2\phi_x + (1+\lambda x)z\phi_z = G(x, z, \phi)$.

We solve it using the method of characteristics: $\phi(x, z) = \psi(t)$ where $\dot{x} = x^2$, $\dot{z} = z(1+\lambda x)$, $\dot{\psi} = G(x, z, \psi)$. Here t can be replaced by x, i.e. we get $x^2\psi'_x = G(x, z, \psi)$, $z = Cx^\lambda \mathrm{e}^{-1/x}$. This is a family of equations depending on C.

Now we proceed as in the previous point. We put $\psi = w\mathrm{e}^{-1/x}$ where $w = w(x, C)$ satisfies the equation

$$x^2 w' = G(x, z, w), \quad z = Cx^\lambda \mathrm{e}^{-1/x},$$

analogous to (3.21). We replace it by the integral equation

$$w(x, C) = \int_0^x G\bigl(s, Cs^\lambda \mathrm{e}^{-1/s}, w(s, C)\bigr) s^{-2}\,\mathrm{d}s,$$

which we solve in the space of w's satisfying the estimate $|w| < K|z|^2$ for some large constant K.

Using the same estimates as in the previous point (with the same choice of path of integration) one shows that this integral operator satisfies the assumption of the Leray–Schauder–Tikhonov theorem.

We refer the reader to [40] for more details. □

4. Bogdanov–Takens singularity

The subjects of investigation in this section are germs at $0 \in \mathbb{C}^2$ of analytic vector fields of the form

$$\dot{x} = y + \cdots, \qquad \dot{y} = \cdots, \tag{4.1}$$

i.e. with nilpotent linear part. Our aim is to find orbital normal forms for them (see Definition 3.1).

There was done some work on the formal orbital normal forms for the systems with nilpotent linear part. F. Takens [78] in 1974 proved that the system (4.1) can be formally reduced to

$$\dot{x} = y + a(x), \qquad \dot{y} = b(x) \tag{4.2}$$

where

$$a(x) = a_r x^r + a_{r+1} x^{r+1} + \cdots, \qquad b(x) = b_{s-1} x^{s-1} + b_s x^s + \cdots \tag{4.3}$$

are some formal power series (see Theorem 4.2 below). Some authors use the following, equivalent to (4.2), prenormal form (see Remark 4.3 below)

$$\dot{x} = y, \qquad \dot{y} = b(x) + yc(x).$$

Since these forms are not the complete normal forms, we shall call them the *Takens prenormal forms*. In order to obtain the form (4.2) Takens uses only changes of variables x, y but not the time.

DEFINITION 4.1. (See [76].) If $s < 2r$ in (4.3) then we call this case the *generalized cusp case*. The case with $s > 2r$ will be called the *generalized saddle–node case* and the case with $s = 2r$ we call the *generalized saddle case*.

4.1. *Formal orbital normal form*

We begin with the following result of Takens

THEOREM 4.2. (See [78].) *There is a formal change of the variables* (x, y) *which reduces the vector field* (4.1) *to the Takens prenormal form* (4.2).

PROOF. We use a composition of infinite series of transformations of the form $\mathrm{id} + Z$, i.e.

$$(x, y) \to (x_1, y_1) = (x, y) + Z(x, y),$$

$x_1 = x + Z_1(x, y)$, $y_1 = y + Z_2(x, y)$, where $Z_1(x, y)$ and $Z_2(x, y)$ are homogeneous polynomials of degree k. We shall treat also Z as a vector field, $Z = Z_1\partial_x + Z_2\partial_y$.

Let $V = y\partial_x + \sum_{j>1} V^{(j)}(X)$, where $V^{(j)}$ are homogeneous summands of the vector field V. Comparing the terms of degree k in the transformed vector field $(\mathrm{id} + Z)^* V = (\mathrm{id} + Z)_*^{-1} V \circ (\mathrm{id} + Z)$ we obtain the equation

$$[Z, y\partial_x] + V^{(k)} = \left(V^{(k)}\right)^{\text{Takens}} \tag{4.4}$$

where $(V^{(k)})^{\text{Takens}}$ is a term from the Takens prenormal form, $(V^{(k)})^{\text{Takens}} = a_k x^k \partial_x + b_k x^k \partial_y$.

The operator $[\cdot, y\partial_x]$, written in the components, acts on $Z_1\partial_x + Z_2\partial_y$ as follows

$$Z_1\partial_x + Z_2\partial_y \to (Z_2 - y\partial Z_1/\partial x)\partial_x - y\partial Z_2/\partial x \partial_y. \tag{4.5}$$

Equation (4.4) is the *Takens homological equation* and operator (4.5) is the *Takens homological operator*.

Applying formula (4.5) to Eq. (4.4) we see that we can cancel all the terms in the y-component of $V^{(k)}$ divisible by y and, when Z_2 is fixed, we can also cancel the terms divisible by y in the x-component. In this way we obtain the formal Takens prenormal form (4.2). □

REMARK 4.3. The equivalent to (4.1) preliminary normal forms are

$$\dot{x} = y, \qquad \dot{y} = b(x) + yc(x)$$

and

$$\dot{x} = y + \mu x c(x), \quad \dot{y} = b(x) + yc(x), \quad \mu > 0.$$

Indeed, in the first case we make the substitution $y_1 = y + a(x)$. (Note that here we do not need any restrictions).

In the second case we make the substitution $y_1 = y + d(x)$ with $d(x)$ satisfying the equation $\mu x d' = -d + a(x)$. We have $d(x) = \mu^{-1} x^{-1/\mu} \int_0^x s^{1/\mu - 1} a(s)\,\mathrm{d}s$. We see that, if $\mu > 0$, then $d(x)$ is well defined; as a formal power series if $a(x)$ is formal, and as an analytic function if $a(x)$ is analytic. We see also that $d(x) = \mathrm{const} \cdot x^r + \cdots$ if $a(x) = \mathrm{const} \cdot x^r + \cdots$.

Generally, if there exist two analytic separatrices $y = u_1 x^r + \cdots$ and $y = u_2 x^r + \cdots$ then one firstly transforms these separatrices to $y = u_{1,2} x^r$. In such case the vector field takes the form

$$V_H + g(x, y) E_H,$$

where V_H and E_H are given in (4.8) and (4.9) below (see [47] and [76]).

PROPOSITION 4.4. (See [13].) *Let $s < \infty$. There exists a change of the variables (x, y) and of the time which reduces vector field* (4.2) *to the form*

$$\left[y + a(x)\right]\partial_x + x^{s-1}\partial_y. \tag{4.6}$$

Moreover, if vector field (4.2) *is analytic then also the vector field* (4.6) *is analytic.*

PROOF. Assume that $b(x) = x^{s-1}b_1(x), b_1(0) \neq 0$. Our aim is to reduce $b_1(x)$ to 1.

We apply the change $x_1 = x\lambda(x)$, $\mathrm{d}t/\mathrm{d}t_1 = \eta(x)$, which should satisfy the equations $\mathrm{d}x_1/\mathrm{d}t_1 = y + a_1(x_1)$, $\mathrm{d}y/\mathrm{d}t_1 = x_1^{s-1}$. Comparing the terms $x_1^{s-1}\partial_y$ and $y\partial_{x_1}$ we get the conditions $\eta(x) \cdot (x\lambda(x))' = 1$, $\eta(x)b_1(x) = \lambda^{s-1}(x)$, or the Bernoulli equation $x\lambda' + \lambda = b_1(x)\lambda^{1-s}$. It has the solution

$$\lambda(x) = sx^{-1}\left[\int_0^x \tau^{s-1}b_1(\tau)\,\mathrm{d}\tau\right]^{1/s}.$$

This solution is an analytic function when $b_1(x)$ is analytic. □

The form (4.6) will be called the *Bogdanov–Takens prenormal form*.

The formal orbital classification of vector fields (4.2) requires additional partition of the space of such vector fields into some classes. Let

$$n = \min\left(r, \frac{s}{2}\right) \in \frac{1}{2}\mathbb{Z}, \tag{4.7}$$

where r, s are defined in (4.3). Introduce a quasi-homogeneous gradation $\widetilde{\deg}$ by $\widetilde{\deg}\, x = -\widetilde{\deg}\, \partial_x = 1$, $\widetilde{\deg}\, y = -\widetilde{\deg}\, \partial_y = n$. Denote

$$V_H = (y + ax^n)\partial_x + bx^{2n-1}\partial_y, \tag{4.8}$$

the lowest $\widetilde{\deg}$-part of the vector field V in (4.2) with $\widetilde{\deg}\, V_H = n - 1$, and let

$$E_H = x\partial_x + ny\partial_y \tag{4.9}$$

be the *quasi-homogeneous Euler field* with $\widetilde{\deg} E_H = 0$.

Note that one can change the pair (a, b) in (4.8) to $(\nu^2 a, \nu b)$, $\nu \in \mathbb{C}^*$.

Putting formally $z = x^n$ and dividing by x^{n-1}, we get from (4.8) the linear system

$$\dot{z} = naz + ny, \qquad \dot{y} = bz. \tag{4.10}$$

Its eigenvalues are equal $\lambda_{1,2} = \frac{n}{2}(a \mp \sqrt{a^2 + 4b/n})$.

DEFINITION 4.5. We call (4.10) the *principal linear system*.

We make a subtler division (than in Definition 4.1) of the set of Bogdanov–Takens singularities:

- C_{odd}: generalized (odd) cusp with $(a, b) = (0, 1)$ and s odd; here the ratio $\lambda_1/\lambda_2 = -1$.
- $S_{k:-l}$: generalized saddle, or generalized cusp with $s = 2n = 2r$ even, when $\lambda_1/\lambda_2 = -k/l \in \mathbb{Q}_-$.
- S_λ: generalized saddle, when $\lambda_1/\lambda_2 = \lambda \in \mathbb{R}_- \setminus \mathbb{Q}$.
- F: generalized saddle with $\lambda_1/\lambda_2 \in \mathbb{C} \setminus \mathbb{R}$.
- $N_{k:l}$: generalized saddle with $\lambda_1/\lambda_2 = k/l \in \mathbb{Q}_+$.

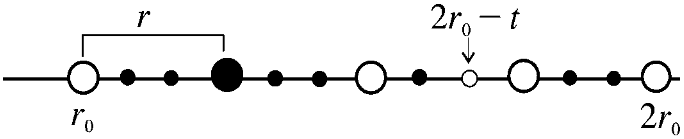

Fig. 12.

- N_λ: generalized saddle with $\lambda_1/\lambda_2 = \lambda \in \mathbb{R}_+$.
- SN: generalized saddle–node, i.e. $(a, b) = (1, 0)$ and $\lambda_1/\lambda_2 = 0$.

Note that in the cases $S_\#$ (respectively F, $N_\#$, SN) the principal linear system (4.10) is a saddle (respectively focus, node, saddle–node).

In the following theorems we present a classification of vector fields from each of the above classes. These fields are of the form $V = V_H + W$, where W is of higher order with respect to the quasi-homogeneous. Each class contains the singularity V_H which is of infinite codimension (as $W \equiv 0$).

Below the notation $j = k(s)$ means $j = k \bmod s$.

THEOREM 4.6. (See [47,76].) *Any vector field from the class* C_{odd} *is formally orbitally equivalent either to* V_H*, or to* $V_H + (x^r + \sum_{j \geqslant r, j \neq 0(s)} a_j x^j)\partial_x$*, where* $r > \frac{s}{2}$*,* $r \neq 0(s)$.

EXAMPLE 4.7. In the usual cusp case, i.e. $s = 3$, equivalent to the above is the following form

$$V_H + \big[A_0(H) + xA_1(H)\big]E_H,$$

where $H = \frac{1}{2}y^2 - \frac{1}{3}x^3$ is the first integral (Hamiltonian) of V_H, used by F. Loray [48] and by M. Canalis-Durand and others [19,20].

THEOREM 4.8. (See [77].) *Any vector field from the class* $S_{k:-l}$, $\gcd(k, l) = 1$, *is formally orbitally equivalent either to* V_H*, or to*

$$V_H + x^t\big(1 + \phi(x)\big)\partial_x,$$

where $t > r$ *and the series* $\phi(x)$ *are of the following forms* (*with* $r_0 = (k + l)r$):

(a) $t \neq 0(r)$ *and* $\phi(x) = \sum_{j \neq 0(r_0),\ j+t \neq 0(r) \text{ or } j+t=r(r_0)} a_j x^j$ (*see Fig.* 12);

(b) $t = p_0 r_0 + r$ *and* $\phi(x) = a_{p_0 r_0} x^{p_0 r_0}$;

(c) $t = p_0 r_0 + r$ *and* $\phi(x) = a_{p_0 r_0} x^{p_0 r_0} + a_{j_0} x^{j_0} + \sum_{j > j_0, j \neq 0(r),\ j \neq j_0 + p_0 r_0} a_j x^j$*, where* $a_{j_0} \neq 0$ *for some* $j_0 > 0$, $j_0 \neq 0(r)$.

THEOREM 4.9. (See [77].) *Any vector field from the classes* S_λ, F, N_λ, $N_{k:l}$ *with* $k, l > 1$, $\gcd(k, l) = 1$, *is formally orbitally equivalent either to* V_H, *or to* $V_H + (x^t + \sum_{j \neq 0(r),\ j > t} a_j x^j)\partial_x$ *where* $t \neq 0(r)$.

THEOREM 4.10. (See [77].) *Any vector field from the class $N_{k:1}$ is formally orbitally equivalent either to V_H, or to $V = V_H + x^{kr}\partial_x$ for $k > 1$, or to $V = V_H + (cx^{kr} + x^t + \sum_{j\neq 0(r),\ j\neq t+kr,\ j>t} a_j x^j)\partial_x$ where $t > r$ and $t \neq 0(r)$, $k \geqslant 1$, and $c = 0$ for $k = 1$.*

THEOREM 4.11. (See [75].) *Any vector field from the class SN is formally orbitally equivalent either to V_H, or to*

$$V_H + x^{s-r-1}\bigl(1+\phi(x)\bigr)E_H,$$

where the series ϕ is of one of the following forms:

(a) $\phi = \sum_{j\neq 0(r)} b_j x^j$ *if* $s \neq 0(r)$;

(b) $\phi = b_{m_0 r} x^{m_0 r}$ *if* $s = (m_0+2)r$;

(c) $\phi = b_{m_0 r} x^{m_0 r} + b_{j_0} x^{j_0} + \sum_{j>j_0,\ j\neq 0(r),\ j\neq j_0+n_0 r} b_j x^j$ *where also* $s = (m_0+2)r$ *and* $b_{j_0} \neq 0$, *for* $j_0 \neq 0(r)$.

REMARK 4.12. The above theorems say nothing about the uniqueness of the presented normal forms. In fact, they are unique relative to an action of a finite group of changes. Each vector field is either of the type $V_H + x^m(1+\phi(x))\partial_x$ or of the type $V_H + x^m(1+\phi(x))E_H$. We consider the changes $x \to \alpha x$, where α is a root of unity of fixed order (e.g. $\alpha^{2r-s} = 1$ for C_{odd}) and we should have $\tilde{\phi}(x) \equiv \phi(\alpha x)$ in order that $V_H + x^m(1+\tilde{\phi}(x))\partial_x$ is equivalent to $V_H + x^m(1+\phi(x))\partial_x$, etc.

We begin the proof of Theorems 4.6, 4.8–4.10 and 4.11. They run along the same scheme. So, we present the general method, but detailed calculations will be provided only for resonant generalized saddle (Theorem 4.8).

The orbital changes rely on application of the conjugations

$$V \to \mathcal{P}_V(Z) := (\mathrm{Ad}_{\exp Z})_* V$$

and multiplications $V \to (1+\chi)V$. Here $Z = Z_1\partial_x + Z_2\partial_y$ is a vector field (formal or analytic), $\exp Z$ is the phase flow diffeomorphism (after the time 1), Ad_h is the adjoint action of a diffeomorphism h on the Lie algebra of vector fields and χ is a function (formal or analytic).

Note that if Z is parallel to V, $Z = \kappa(x,y)V$, then the map $\exp Z$ preserves the phase portrait of V and the field $\mathcal{P}_V(\kappa V)$ is also parallel to V. In order to avoid this ambiguity, one uses the notion of a bi-vector field introduced by R. Bogdanov in [13]. If $V = V_1\partial_x + V_2\partial_y$, then we define the *bi-vector field*

$$Z \wedge V = \Omega \cdot \partial_x \wedge \partial_y \tag{4.11}$$

where $\Omega(x,y) = V_2 Z_1 - V_1 Z_2$. One can say that Ω measures the component of Z transversal to V. If $\Omega = 0$ and V has isolated singularity, then $Z = \kappa V$ for some function κ.

This suggests that one should consider the map

$$Z \to \frac{\mathcal{P}_V(Z) \wedge V}{\partial_x \wedge \partial_y}, \tag{4.12}$$

from the space $(\mathbb{C}[[x,y]])^2$ of formal vector fields to the space $\mathbb{C}[[x,y]]$ of formal functions. Since the map $Z \to \mathcal{P}_V(Z)$ is non-linear, the map (4.12) cannot be factorized to a map from $\mathbb{C}[[x,y]]$ to $\mathbb{C}[[x,y]]$. But the linear part of $\mathcal{P}_V(\cdot)$ equals $-\mathrm{ad}_V(\cdot)$ and we have the following well the defined linear map

$$\mathcal{L}_V\Omega = -\frac{\mathrm{ad}_V Z \wedge V}{\partial_x \wedge \partial_y}.$$

Standard calculations give the following formula

$$\mathcal{L}_V\Omega = \dot{\Omega} - \operatorname{div} V \cdot \Omega \tag{4.13}$$

where $\dot{\Omega} = V(\Omega) = \partial\Omega/\partial V$ and div denotes the divergence.

We shall prove our theorems using the linear operator $\mathcal{L}_V$ (with different V's) and also the quasi-homogeneous gradation $\widetilde{\deg}$; we eliminate recursively terms of growing quasi-homogeneous degree. If $U = U_1\partial_x + U_2\partial_y$ is the part of V ('transversal' to V) devoted to killing, then we have the *bi-vector homological equation*

$$\mathcal{L}_V\Omega + \Theta = 0, \quad \Theta = \frac{U \wedge V}{\partial_x \wedge \partial_y}. \tag{4.14}$$

Having solved the bi-vector homological equation, we get some function Ω. Having the function Ω, we find the vector field from the equation $Z_1V_2 - Z_2V_1 = \Omega$; assuming $V_1 = y + ax^n + \cdots$, $V_2 = bx^{2n-1} + \cdots$ it is seen that the solution exists (provided that the expansion of Ω begins from terms of $\widetilde{\deg} \geqslant n+2$). The application of $(\mathrm{Ad}_{\exp Z})_* V$ destroys U, leaving only terms of the form $\sigma(x,y)V$. The latter will be reduced using the multiplication $(1-\sigma)V$. The terms non-linear in Z are of higher quasi-homogeneous degree and are eliminated in further steps of the recursive process.

The whole algorithm of reduction is divided into three general stages. Firstly we approximate the homological operator $\mathcal{L}_V$ by $\mathcal{L}_{V_H}$: we determine its kernel in $\mathbb{C}[[x,y]]$ and a subspace complementary to its image. Next, we use the operator $\mathcal{L}_{V_H + x^t\partial_x}$ to Ω's from $\ker \mathcal{L}_{V_H}$ to reduce some additional terms; here $x^t\partial_x$ is the first term not reduced in the previous step. In the third step we use the operator $\mathcal{L}_{V_H + x^t\partial_x + \mathrm{const}\cdot x^u\partial_x}$.

Denote by $\mathcal{X}_{m,i} \approx \mathbb{C}^{m+1}$ the space of polynomials Ω of the form

$$\Omega = \omega_0 x^{mn+i} + \omega_1 x^{(m-1)n+i} y + \cdots + \omega_m x^i y^m,$$

i.e. of quasi-homogeneous degree $\widetilde{\deg}\,\Omega = mn + i$.

LEMMA 4.13.

(a) *The equation $\mathcal{L}_V\Omega = 0$ means that the function Ω is the inverse integrating factor for the vector field V, i.e.* $\operatorname{div}(\Omega^{-1}V) = 0$.

(b) *In the case of generalized resonant saddle $S_{k:-l}$ the operator $\mathcal{L}_{V_H}$ acts between the spaces $\mathcal{X}_{m,i}$ and $\mathcal{X}_{m+1,i-1}$ (of dimensions $m+1$ and $m+2$ respectively) when $i > 0$, and between the spaces $\mathcal{X}_{m,0}$ and $\mathcal{X}_{m,r-1}$ (of the same dimension $m+1$) when $i = 0$.*

(c) *In the case of generalized resonant saddle* $S_{k:-l}$ *we have* $\ker \mathcal{L}_{V_H} = (y-u_1x^r)^{pk+1}\times (y-u_2x^r)^{pl+1}\cdot\mathbb{C}$, $r=n$, *if* $mn+i=(pk+pl+2)r$, *i.e. in* $\mathcal{X}_{pk+pl+2,0}$, $p=1,2,\ldots$ (*here* $y=u_{1,2}z$ *are the equations of separatrices in* (4.10)).

PROOF. The first statement follows from the relation $\operatorname{div}(fV)=V(f)+f\cdot\operatorname{div}V$ and the second statement is rather obvious.

If Ω is the inverse integrating multiplier for V_H then the field $X_H=V_H/\Omega$ is Hamiltonian with quasi-homogeneous Hamilton function H, i.e. V_H has quasi-homogeneous first integral. The unique quasi-homogeneous first integrals take the form

$$H=(y-u_1x^r)^{A\lambda_2}(y-u_2x^r)^{-A\lambda_1},\quad A\in\mathbb{C},$$

where $\lambda_{1,2}$ are the eigenvalues of the linear system (4.10). Then

$$X_H=V_H\cdot\left[(y-u_1x^r)^{1-A\lambda_2}(y-u_2x^r)^{1+A\lambda_1}\right]^{-1}.$$

We see that the only possibility that the function $\Omega=(y-u_1x^r)^{1-A\lambda_2}(y-u_2x^r)^{1+A\lambda_1}$ is a polynomial is just as in the statement (c). ☐

COROLLARY 4.14. *In the case* $i>0$ *we have* $\ker\mathcal{L}_{V_H}|\mathcal{X}_{m,i}=0$ *and* $\operatorname{Im}\mathcal{L}_{V_H}\mathcal{X}_{m,i}$ *is of codimension* 1, *with* $x^{(m+1)r+i-1}\cdot\mathbb{C}$ *as a complementary subspace to* $\operatorname{Im}\mathcal{L}_{V_H}\mathcal{X}_{m,i}$.

In the case $i=0$ *either* $\ker\mathcal{L}_{V_H}|\mathcal{X}_{m,0}=0$ *and* $\operatorname{coker}\mathcal{L}_{V_H}|\mathcal{X}_{m,0}=0$, *or* $\ker\mathcal{L}_{V_H}|\mathcal{X}_{m,0}\neq 0$ *and* $\operatorname{Im}\mathcal{L}_{V_H}|\mathcal{X}_{m,i}$ *is of codimension* 1 *with* $x^{mr+r-1}\cdot\mathbb{C}$ *as a complementary subspace.*

PROOF. The only fact we have to prove is the statement about complementary subspaces. On the one hand, it follows from the Bogdanov–Takens prenormal form; i.e. the reduction to $(y+a(x))\partial_x+bx^{2r-1}\partial_y$ (see [76]).

One can see it also after composing $\mathcal{L}_{V_H}$ with the projection π of $\mathcal{X}_{m,0}$ onto the m-dimensional subspace of polynomials divisible by y. In the monomial basis in the case $i>0$ the operator $\pi\circ\mathcal{L}_{V_H}$ becomes upper-triangular with entries $jr+i\neq 0$ on the diagonal. In the case $i=0$ the left-down minor of dimension m is upper-triangular with entries $jr\neq 0$ on the diagonal. ☐

The polynomials from $\ker\mathcal{L}_{V_H}$, which are described in Lemma 4.18, form inverse integrating factors also for some vector fields which are not quasi-homogeneous.

Consider the function

$$F(x,y)=\frac{1}{(y-u_1x^r)^{pk}(y-u_2x^r)^{pl}}+\nu\cdot\ln\left[\frac{yx^{-r}-u_1}{yx^{-r}-u_2}\right]$$

where ν is a constant. It is the first integral of the vector field

$$V_H+\eta\cdot(y-u_1x^r)^{pk}(y-u_2x^r)^{pl}x^{r-1}E_H \tag{4.15}$$

where $\eta = \nu(u_2 - u_1)/p(k+l)$. The inverse integrating factor is

$$-(pk+pl)^{-1}(y-u_1x^r)^{pk+1}(y-u_2x^r)^{pl+1}, \tag{4.16}$$

the same as in Lemma 4.13(c).

Note that the vector field (4.15) consists of two quasi-homogeneous parts (of degrees $r-1$ and $r-1+rp(k+l)$). The first integral also consists of two quasi-homogeneous parts, of degrees $-(k+l)r$ and 0. Note also that the level curves $F(x,y)=f$, $f \neq \infty$ are non-algebraic, only the curve $F=\infty$ is algebraic.

It turns out that this example presents the only situations (in a sense), where a non-quasi-homogeneous vector field has a polynomial inverse integrating factor.

LEMMA 4.15. *Consider a vector field of the form $V = V_H + V_1$ where V_H has the principal linear part a $(k:-l)$-resonant saddle,* $\gcd(k,l)=1$, *and V_1 is a quasi-homogeneous field of degree $d = \widetilde{\deg} V_1 > r-1$and such that*

$$d+1 \neq 0(r).$$

Then V does not admit any inverse integrating factor of the form

$$\Omega_0 + \Omega_1 + \cdots \tag{4.17}$$

where $\Omega_0 \in \ker \mathcal{L}_{V_H}$, Ω_1 is a quasi-homogeneous polynomial of degree $d-r+1$ and "$\cdots$" means higher degree terms.

Moreover, for the vector field (4.15) *the only possible inverse integrating factor of the form* (4.17) (*with $\Omega_0 \in \ker \mathcal{L}_{V_H}$, and Ω_1 polynomial*) *is the function* (4.16).

PROOF. Following Remark 4.3 we can assume that V_1 of the form $g(x,y)E_H$. Then, after applying the quasi-homogeneous blowing-up $(x,u) \to (x,y) = (x, ux^r)$, we get the Bernoulli equation

$$\frac{\mathrm{d}x}{\mathrm{d}u} = \frac{u+a}{-r(u-u_1)(u-u_2)} x + \frac{\tilde{g}(u)}{(u-u_1)(u-u_2)} x^{d-r+2}$$

with $\tilde{g} = -g(1,u)/r$. This equation has the first integral

$$G = \frac{1}{(y-u_1x^r)^{\alpha}(y-u_2x^r)^{\beta}} + c\int^u \frac{\tilde{g}(u)\,\mathrm{d}u}{(u-u_1)^{\alpha+1}(u-u_2)^{\beta+1}},$$

where $\frac{\alpha}{\beta} = \frac{k}{l}$ and $(\alpha+\beta)r = d+1-r$.

The first integral G corresponds to the inverse integrating factor $M = (y-u_1x^r)^{\alpha+1}(y-u_2x^r)^{\beta+1}$ which cannot be polynomial (by our choice of d). Any other first integral for V is a functions of the primitive integral G. But taking it in the form $F = G^{\gamma}$ we find the inverse integrating factor equal $M \cdot G^{1-\gamma}$, which cannot be written in the form (4.17); it would be equal $\Omega_0 + \Omega_1 + \cdots$ where Ω_1 is not a polynomial. It is also clear that other forms of first integral (like $F = G^{\gamma} + \text{const} \cdot G^{\delta}$) do not lead to a right inverse integrating factor.

The second statement is proved in the same way. $\square$

PROOF OF THEOREM 4.8. By Lemma 4.14 the operator $\mathcal{L}_{V_H}$ applied to the space $\mathcal{X}_{m,i}$ (of quasi-homogeneous Ω's) has non-zero kernel only in one case. It occurs when $mr + i = (pk + pl + 2)r$, i.e. $m = pk + pl + 2$, $i = 0$. This kernel is 1-dimensional and is generated by the polynomial $\Omega_0 = (y - u_1 x^r)^{pk+1}(y - u_2 x^r)^{pl+1}$.

The cokernel of $\mathcal{L}_{V_H} : \mathcal{X}_{m,0} \to \mathcal{X}_{m,r-1}$ is equal 0 for $m \neq pk + pl + 2$ and is 1-dimensional otherwise. Also $\operatorname{coker}(\mathcal{L}_{V_H} : \mathcal{X}_{m,i} \to \mathcal{X}_{m+1,i-1})$ is 1-dimensional for $i > 0$.

If $\operatorname{coker} \mathcal{L}_{V_H} \neq 0$ then we can assume that it is generated by a power $\Theta = x^{\beta}$, $\beta = (pk + pl + 2)r + r - 1$ or $\beta = (m + 1)r + i - 1$ $(0 < i < r)$; it corresponds to the field (via $\Theta = W \wedge V_H / \partial_x \wedge \partial_y$):

$$W = x^{p(k+l)r+r} \partial_x \quad \text{or} \quad W = x^{(m-1)r+i} \partial_x$$

respectively. Instead of $x^{p(k+l)r+r-1}\partial_x$ in the first case we can take $W = H^p x^{r-1} E_H$, where $H = (y - u_1 x^r)^k (y - u_2 x^r)^l$. Therefore application of the homological operator, associated with the leading part of V_H, reduces V to

$$V_H + \sum b_{pj} H^p x^{r-1} E_H + \sum_m \sum_{i=1}^{r-1} a_{m,i} x^{mr+i} \partial_x \tag{4.18}$$

where b_p, $a_{m,i}$ are complex coefficients. We have three possibilities:

- $V = V_H$;
- $V = V_H + a_{m_0,i_0} x^{m_0 r + i_0} \partial_x + \cdots$, $i_0 \neq 0$, $a_{m_0,i_0} = 1$;
- $V = V_H + b_{p_0} H^{p_0} x^{r-1} E_H + \cdots$, $b_{p_0} = 1$.

In the second case dominating is the term $a_t x^t \partial_x$ with $t = m_0 r + i_0 \neq 0(r)$. Then we use the operator $\mathcal{L} = \mathcal{L}_{V_H} + \mathcal{L}_{x^t \partial_x}$ to functions

$$\Omega = \Omega_0 + \Omega_1, \qquad \Omega_0 \in \ker \mathcal{L}_{V_H},$$

to reduce further terms. Here, by Lemma 4.13, $\Omega_0 = \text{const} \cdot H^j (y - u_1 x^r)(y - u_2 x^r)$, $j = 1, 2, \ldots$, and by Lemma 4.15 the corresponding operator defines an isomorphism between suitable spaces, of Ω's and of quasi-homogeneous functions Θ's (the kernel of $\mathcal{L}$ is zero). This gives the point (a) of Theorem 4.8.

In the third case dominating is the term $W_0 = H^{p_0} x^{r-1} E_H$, corresponding to $x^t \partial_x$ with

$$t = p_0 r_0 + r, \qquad r_0 = (k + l)r$$

(see the cases (b) and (c) in Theorem 4.8). Thus we apply the operator $\mathcal{L} = \mathcal{L}_{V_H} + \mathcal{L}_{W_0}$ to functions of the form $\Omega_0 + \Omega_1$, where $\Omega_0 = c H^q (y - u_1 x^r)(y - u_2 x^r)$, $c \in \mathbb{C}$, and Ω_1 is quasi-homogeneous with $\widetilde{\deg}\,\Omega_1 - \widetilde{\deg}\,\Omega_0 = p_0 r_0$. Here $q = 1, 2, \ldots$.

Let $q = p_0$. By the example with the vector field (4.15) we see that the corresponding operator $\mathcal{L}$ has non-zero kernel $(\Omega_0 + \Omega_1) \cdot \mathbb{C} = (H^{p_0}(y - u_1 x^r)(y - u_2 x^r) + 0) \cdot \mathbb{C}$ and the operator is not surjective. This means that the term $x^{t+p_0r_0}\partial_x = x^{r+2p_0r_0}\partial_x$ (corresponding to $H^{2p_0}x^{r-1}E_H$ in (4.18)) cannot be killed.

Let $q \neq p_0$. Then Lemma 4.15 asserts that the corresponding kernel is 0. Therefore all the terms $x^{t+qr_0}\partial_x$ with $q \neq p_0$, corresponding to $H^{p_0+q}x^{r-1}E_H$ in (4.18), can be killed.

In the case (b) form the thesis of Theorem 4.8 we have the situation where all other terms $a_{m,i}x^{mr+i}\partial_x$ in (4.18) are equal zero; (there remain only two terms $b_pH^px^{r-1}E_H$ with $p = p_0, 2p_0$).

If there exists a term $W_1 = a_{j_0}x^{j_0+t}\partial_x$, with j_0 not divisible by r, then we use the operator $\mathcal{L} = \mathcal{L}_{V_H} + \mathcal{L}_{W_0} + \mathcal{L}_{W_1}$ applied to

$$\Omega = \text{const} \cdot H^{p_0}(y - u_1x^r)(y - u_2x^r) + \Omega_1 + \Omega_2 = \Omega_0 + \Omega_2,$$

where $\Omega_0 \in \ker \mathcal{L}_{V_H+W_0}$, in order to kill additional term. Here $\ker \mathcal{L} = 0$ and the operator $\mathcal{L}$ is a surjection. This gives the case (c) of Theorem 4.8.

The remaining part of Theorem 4.8 is standard. □

Other theorems of this subsection are proved along the same lines as in the latter proof.

REMARK 4.16. Let us say some words about the classification of the Bogdanov–Takens singularities with respect to conjugation, not orbital equivalence (see Definition 3.1).

Firstly, A. Baider and J. Sanders [7,8] showed that in the generalized cusp case, i.e. $s < 2r$, the unique (non-orbital) normal form is following

$$V_H + \Bigg(\alpha_{2s-1}x^{2s-1} + \sum_{j>s-1,\ j\neq -2,-1,r-2(s)} \alpha_j x^j\Bigg)\partial_y + \Bigg(\sum_{j\geqslant r-1,\ j\neq -1(s)} \beta_j x^j\Bigg)(x\partial_x + y\partial_y).$$

They obtained also a unique normal form in the generalized saddle case, but it is more complicated (and we do not present it here).

Next, H. Kokubu, H. Oka and D. Wang [44] considered the case of non-resonant generalized saddle S_λ for $r = 2$ and $s = 4$. They reduced the system to so-called first order normal form (which is unique)

$$V_H + \Bigg(\sum_{j\geqslant 4} \alpha_j x^j\Bigg)\partial_y.$$

X. Wang, G. Chen and D. Wang [84] considered the generalized cusp singularity with $s = 3$ and $r \geqslant 2$. They obtained the following unique normal forms

$$V_H + \alpha_3x^3\partial_y + \big(xf(x^3) + x^3g(x^3)\big)y\partial_y, \qquad f(0) \neq 0,$$

and

$$V_H + (\alpha_3x^3 + \alpha_5x^5)\partial_y + \big(x^4f(x^3) + x^3g(x^3)\big)y\partial_y,$$

provided $110f(0) \neq 183\alpha_3 g(0)$.

Also A. Algaba, E. Freire and E. Gamaro [2] studied the problem and obtained some list of (non-orbital) normal forms.

Nevertheless the problem of classification of the nilpotent singularities with respect to formal conjugation is still not finished. Probably the list of formal orbital normal forms given above would be helpful to complete this classification.

4.2. *Analytic Takens prenormal form*

The main result of this subsection solves the old problem of analyticity of the prenormal form obtained by F. Takens.

THEOREM 4.17. (See [76,49].) *The Takens prenormal form* $\dot{x} = y + a(x)$, $\dot{y} = b(x)$ *of the singularity* $\dot{x} = y + \cdots$, $\dot{y} = x^{s-1}\cdots$, $s < \infty$, *obtained in the proof of Theorem* 4.2 *is analytic. This implies also that the Bogdanov–Takens prenormal form* (4.6) *is analytic.*

REMARK 4.18. The theorem holds true also when $s = 2$. Then the singular point is a saddle with the $1 : -1$ resonance and Theorem 4.18 gives an analytic prenormal form for such saddles.

The theorem holds true also when $s = \infty$, i.e. in the case of generalized saddle–node of infinite codimension. Here the vector field has formal first integral, $H(x, y) = y$ in the formal Takens coordinates. It is easy to get analyticity of this integral (see [75] and [86]).

Theorem 4.18 has two proofs. One proof from [76] relies on estimates of the successive approximations from the proof of the Takens theorem. It seems that it can be generalized to the cases of higher dimensional nilpotent singularities of vector fields. Another proof from [49] is geometrical and uses a preparation theorem for holomorphic foliations. Below we present the latter proof with details.

PROOF OF THEOREM 4.17. Following [49] we shall prove even more general statement: *if the linear part of a holomorphic germ* $V = V_0$ *of vector field at* $0 \in \mathbb{C}^2$ *is not radial, i.e. not of the form* $\mu(x\partial_x + y\partial_y)$, *then there exist local analytic coordinates* x, y *in which* $V_0 = (y + a(x))\partial_x + b(x)\partial_y$ *for some analytic germs* a, b.

PROOF. By the non-radiality assumption it is easy to find linear coordinates in which $dV_0(0) = \left(\begin{smallmatrix} 0 & 1 \\ \alpha & \beta \end{smallmatrix}\right)$. Moreover, we can assume that $V_0 = f\partial_x + g\partial_y$ with $f(0, y) = y$.

In $\mathbb{C} \times \bar{\mathbb{C}}$ we consider the vertical line $L = 0 \times \bar{\mathbb{C}}$ together with its covering defined by $\Delta_0 = 0 \times \{|y| < r\}$ and $\Delta_\infty = 0 \times \{|y| > r/2\}$. Also we denote by $C = \Delta_0 \cap \Delta_\infty$ the intersection *corona* (see [49]).

If $r > 0$ is small enough then the vector field V is well defined on a neighborhood of the closure of Δ_0 and is transverse to this disc outside $y = 0$. By the flow-box theorem there exists a unique germ of a diffeomorphism $\Phi : (\mathbb{C}^2, C) \to (\mathbb{C}^2, C)$, such that $\Phi(0, y) = (0, y)$ and Φ conjugates V_0 to the horizontal vector field $V_\infty = y\partial_x$.

Let us glue the germs of holomorphic surfaces $(\mathbb{C} \times \bar{\mathbb{C}}, \Delta_0)$ and $(\mathbb{C} \times \bar{\mathbb{C}}, \Delta_\infty)$ along the corona by means of the diffeomorphism Φ. We obtain a germ of smooth complex surface

M along a rational curve L with a meromorphic vector field V. Since the x-component of V_0 at C agrees with $y\partial_x$, it follows that the Jacobian of the gluing map Φ takes the form $\mathrm{d}\Phi(0,y)=\left(\begin{smallmatrix}1&0\\ *&1\end{smallmatrix}\right)$ and the embedded rational curve L has zero self-intersection.

V. Savelev [69] proved that in this situation the line L is a regular fiber of some trivial fibration on M, i.e. there exist global coordinates $(x,y):(M,L)\to(\mathbb{C},0)\times\bar{\mathbb{C}}$ sending L onto $\{x=0\}$.

The vector field V has a simple pole along a curve, which we may assume still given by $\{y=\infty\}$. Since $\partial_y=-(1/y)^2\partial_{1/y}$ has second order zero at $\{y=\infty\}$ we can write

$$V=\big[a_0(x)+a_1(x)y\big]\partial_x+\big[b_0(x)+b_1(x)y+b_2(x)y^2+b_3(x)y^3\big]\partial_y. \tag{4.19}$$

The vector field V has exactly one isolated zero, say at $x=y=0$.

The tangency divisor Σ between the foliation $\mathcal{F}$ induced by V and the fibration $\{x=\text{const}\}$ is a smooth curve $\Sigma=\{a_0(x)+a_1(x)y=0\}$ intersecting transversally the line $L=\{x=0\}$. Indeed, the Jacobian of the change from the first chart to the global coordinates at the singular point fixes the y direction, so that the linear part of the vector field takes the form $\left(\begin{smallmatrix}k&l\\ m&n\end{smallmatrix}\right)$, $l\neq0$. Therefore $a_1(0)\neq0$ in (4.19).

We can further simplify (4.19). Note that the admissible changes of the coordinates in $(\mathbb{C},0)\times\widehat{\mathbb{C}}$ are of the form $(x,y)\to(\phi(x),\frac{\alpha(x)y+\beta(x)}{\gamma(x)y+\delta(x)})$.

By straightening one leaf of the foliation $\mathcal{F}$ (i.e. through $(0,\infty)$) we can assume that $\{y=\infty\}$ is a leaf of $\mathcal{F}$. Thus $b_3(x)\equiv0$ in (4.19).

Next, the change $y\to(\mathrm{e}^{\int b_2/a_1})y$ reduces $b_2(x)$ in (4.19) to zero.

By a change of the x coordinate we can assume that $a_1(x)\equiv1$. The change $y\to y-a_1(x)$ straightens the curve Σ to $\{y=0\}$. Hence we can put $a_0(x)\equiv0$.

We obtain the vector field $V=y\partial_x+[b_0(x)+b_1(x)y]\partial_y$ which is equivalent to the Takens field (4.2) (compare Remark 4.3). ☐

Next to consider is the question of analyticity of the final orbital normal forms given in Theorems 4.6, 4.8–4.10 and 4.11.

But, as we noticed in Remark 4.18, in the case $s=2$ we have a $1:-1$ resonant saddle, where the formal normal form is not analytic (see Subsection 3.5). So there is no hope to expect that for $s\geqslant3$ one could prove analyticity of the final formal orbital normal form.

This question for the standard cusp singularity, i.e. $s=3$ and $r=2$, was firstly considered in [19]. There the authors calculated numerically some initial terms in the Loray's normal form

$$V_H+\big(x+A_0(H)\big)E_H,\quad H=y^2/2-x^3/3, \tag{4.20}$$

i.e. the coefficients a_{3j} in the series $A_0(H)=a_3H+a_6H^2+\cdots$ (compare Remark 4.7). These coefficients turned out growing like the Gevrey series of order 2, i.e.

$$a_{3j}\sim CA^{6j}\Gamma(\alpha+6j) \tag{4.21}$$

(compare Definition 3.48). Approximate values of the constants in (4.21) are $C\approx7678015$, $A\approx0.1803$ and $\alpha\approx-37.27$.

In [20] M. Canalis-Durand and R. Schäfke gave a rigorous proof of the divergence of the form (4.21). They proved the following

THEOREM 4.19. (See [20].) *For an analytic vector field*

$$V = V_H + \Delta(x, y)E_H, \tag{4.22}$$

with $H = \frac{1}{2}y^2 - \frac{1}{3}x^3$ *and analytic function* $\Delta = x + \cdots$, *there exists a unique formal series* $\Phi(x, y) = 1 + \cdots$ *such that the formal transformation* $(x, y) \to (x\Phi^2, y\Phi^3)$ *and division by* Φ *reduces* V *to the form* (4.20) *such that* $|a_{3j}| < CA^{6j}(6j)!$ *for some constants* C, A. *The series* $A_0(z^6)$ *is* 1*-summable if* $\arg z$ *is not congruent to* $\pi/6$ *modulo* $\pi/3$.

Moreover, for typical germs Δ, *i.e. outside a hypersurface in the space of such germs, the series* $A_0(H)$ *is divergent.*

REMARK 4.20. (About the proof of Theorem 4.19.) A general vector field which is tangent to the cusp $\{H(x, y) = 0\}$ is reduced to the form (4.22), after division by a non-zero function. The reduction used in the first statement of Theorem 4.19 comes from the Loray's algorithm [47].

The proof of Theorem 4.19 given in [20] is very short. However we cannot present it here with details. It uses so-called Borel transform $\mathcal{B}$ (see Definition 3.47), or its generalization to two variables, and its inverse (so-called Laplace transform).

The main idea of the proof is to solve the suitable conjugation equation in the 'Borel plane'. It turns out that the Borel transform of the series $\Phi(x, y)$ is a meromorphic function with poles. Namely, these poles are responsible for the divergence of the series Φ.

Finally, we note that in the sequent paper [21] Canalis-Durand and Schäfke proved an analogous result when $\Delta(x, y)$ in (4.22) starts from higher order terms and in (4.20) we have $V_H + (A_0(H) + xA_1(H))E_H$. Then the order of summability of the series A_0, A_1 depends on their first non-zero terms. ☐

REMARK 4.21. Recall that in Subsection 3.5 we defined certain holonomy map associated with a saddle or a saddle–node singularity of planar vector field. This holonomy map (or monodromy map) was associated with a loop in a separatrix of the singularity. Also with the nilpotent singularities one can associate certain 1-dimensional object. It is the so-called hidden holonomy group.

Namely, in the resolution π of the singularity one obtains some special divisor E with 3 singular points p_0, p_1, p_2 of the induced foliation $\mathcal{G} = \pi^*\mathcal{F}$. (In the case of ordinary cusp it is the divisor E_3 from Fig. 4.) The *hidden holonomy group* G is formed by the monodromy maps $\Delta_\gamma : D \to D$, of a small disc $D \approx (\mathbb{C}, 0)$ transversal to a point $q \in E^* = E \setminus \{p_0, p_1, p_2\}$. The loops γ run through the fundamental group $\pi_1(E^*, q)$.

In many situations the (analytic) orbital classification of the vector fields V is reduced to the classification of finitely generated subgroups $G \subset \mathrm{Diff}(\mathbb{C}, 0)$ (obeying some natural relations) with respect to conjugation in the group $\mathrm{Diff}(\mathbb{C}, 0)$.

This is an interesting and advanced theory . The interested reader is referred to [23,31, 48,50,61,76,75] and [89] for details.

Subject Index

$1/3.41613062\ldots$ – convergence radius of series (5.64), 529
– spectral radius of operator (7.12), 555
– value of $R_{K,1}/r(K)$ for constant K, 523
β-neighbourhood, 443
$\delta_\Omega(f)$, 540, 557
$\mathrm{GL}_n(\mathbb{R})$, 443
μ-Lipschitzian map, 50
$\mathbb{1}_n$, 443
$\partial\Omega$, 443
$\Sigma^{\mathrm{ed}}(L)$, 194
Θ-divisor, 229

$A(\Gamma)$-module $A_1^t(G)$, 32
Abel identity, 293
Abel map, 228
absolutely irreducible, 13
adjoint, 373, 416
Airy differential equation, 289
algebraic solvability, 624, 627
algebroid solution, 350, 352–356
almost automorphic
– extension, 144, 162, 168
– flow, 144
– function, 144
almost complex structure, 665
almost periodic flow, 143
alternating group, 98
analytic Hadamard–Perron theorem, 632
analytical solvability, 629
arbitrary growth theorem, 344
arranging equivariant spectral data, 74
Arzelà–Ascoli theorem, 473
asymptotic cycle, 609, 654
asymptotic phase, 367, 387, 394–396, 401
auxiliary function, 88
auxiliary G-invariant function, 7

Baker–Akhiezer function, 241
Banach G-representations, 17
Banach vector bundle, 19
basic degree, 45
basic map, 37, 44, 45
Bebutov construction, 136–138, 143, 145
Bebutov flow, 136
Beltrami differential, 667
Beltrami equation, 667
Bessel equation, 611
bi-orientable, 32
bifurcation, 87
Birkhoff Ergodic Theorem, 145
Birkhoff recurrence, 143
BL-condition, 294
BL-conjecture, 294
BL-function, 294
Blaschke-oscillatory, 308, 310
Bloch, 315
Bogdanov–Takens prenormal form, 673
Bogdanov–Takens singularity, 618, 671
Bohr almost periodicity, 143
Borel transform, 651
Borsuk theorem, 473
boundary conditions
– linear
– – periodic, 444
– – three-point, 444
– non-linear
– – separated, 444, 551
– – two-point, 444
boundary value problem
– regular, 443
– singular, 444
bounded mean motion, 178
Briot–Bouquet differential equation, 271, 283, 342, 343
Briuno condition, 658
Brouwer degree, 471
Burnside ring, 28, 29
$B(y,\beta)$, 443

$\mathbb{C}$-complementing, 44
– map, 40, 45
– pair, 40, 45
$C_T^n(\tau, E)$, 510
$C([0,T]\times D, \mathbb{R}^n)$, 443
Camassa–Holm equation, 181

Cameron’s theorem, 158, 161, 167
Carathéodory conditions, 529
center, 3, 94, 624, 625
– isolated, 3
– manifold, 643, 647
center–focus problem, 623
chaotic behaviour, 367, 402, 407
character, 143
– of representation, 15
characteristic
– equation, 54, 77, 93, 114
– operator, 54, 93
– root, 54, 93
– trajectory, 623
Choquet theory, 157, 204
closed
– gap, 253
– operator, 21
Clunie, 337, 339, 345, 352
– lemma, 322
cocycle, 137, 145
coincidence problems, 84
community matrix, 113
complementing function, 60
complete reducibility theorem, 13
completely continuous map, 50
complex function spaces, 307, 312, 314, 320
– Bergman space, 313, 314
– – weighted, 313, 314
– Bloch space, 307, 314
– BMOA, 315
– Dirichlet space, 314
– – weighted, 314
– Hardy space, 307, 310, 313, 332
– – weighted, 332
– Korenblum space, 313, 318
– Nevanlinna class, 313
– normal functions, 315, 322
– Q_p-space, 307, 314
complex isotypical decomposition, 17
complexification, 14
condensing
– field, 50
– map, 50
cone construction, 257
conjugacy class, 11
conjugation, 14
continuation, 278, 356
– along the curve, 276
– of local solutions, 275–277
continued, 336
continuous family of equivariant Fredholm operators of index zero, 85
crossing numbers, 63, 71, 77, 95, 96, 101, 109
cusp, 618, 674, 682

D_β, 443
defect, 337, 338
defining equation, 602
Denjoy cocycle, 180
density of exponential dichotomy, 251
desingularization, 619
dicritical
– davison, 618
– node, 617
diffeomorphism tangent to identity, 633
differential
– field, 343, 348–350
– independence, 349
– of the first kind, 226
– of the second kind, 231
– of the third kind, 229, 231
differentially
– algebraic, 349
– elementary functions, 349
– transcendental, 349
diffusion equation, 113
dihedral group, 98, 122
direct growth problem, 320
disconjugate, 308–310
distal
– extension, 161
– pair, 161
distance, 310
divisor, 227
dominating, 67
– orbit types, 9, 67
Duffing equation, 477
dynamical spectrum, 147, 148, 151

Ecalle–Voronin moduli, 632, 636, 650
Ecalle–Voronin theorem, 636, 639
eigenvalue, eigenfunction, 184
elementary singular point, 617
equilibrium point, 104
equivalence of
– diffeomorphisms, 633, 636, 641, 642, 649
– of linear systems, 596, 602, 608
– of vector fields, 616, 656, 657
equivariant Dugundji theorem, 26
ergodic
– measure, 144
– theory, 144
exceptional divisor, 617
exponent of convergence, 288, 289, 293
exponential dichotomy, 141, 147, 194, 200, 250

Favard property, 139, 161
Favard theory, 165
field, 49
finite oscillation property, 290, 306
finiteness degree, 318
– of growth, 297
first focus quantity, 628
fixed singularities, 326, 335
Floquet exponent, 201
Floquet matrix, 153
Floquet theory, 153, 155, 303
flow, 142, 143
– homomorphism, 143
– isomorphism, 143
folding homomorphism Θ_l, 74
Fredholm operator, 20
Frei theorem, 318
frequency module, 144
function
– (τ, E)-proper, 510
– τ-even, 510
– τ-odd, 510
– approximate determining, 470
– determining, 470
– even, 510
– odd, 510
– T-periodic, 443
fundamental domain, 24

G-action, 10
G-equivariant field, 48
G-equivariant homotopy of compact fields, 49
G-equivariantly homotopic, 49
G-fundamental, 51
G-homotopy, 25
G-invariant norm, 17
G-manifold, 19
G-representation, 12
G-representation conjugate, 14
G-space, 10
G-vector bundle, 19
Gauss hypergeometric equation, 596, 602
generalized Θ-function, 235
generalized cusp, 671
generalized Jacobian variety, 234
generalized Riemann vector, 235
generalized saddle, 671
generalized saddle–node, 671
Gevrey series, 651
Gilbert–Pearson theory, 140, 191, 205
global bifurcation problems, 81
global continuation of bifurcating branches, 109
global Hopf bifurcation, 111
– theorem, 82
global oscillation property, 290, 306
good resolution, 617, 619
Green’s function, 195

H-fixed-point subset, 11
(H)-normality, 27
Haar integral, 15
Hartman argument, 210
Hausdorff metric, 21
Herglotz function, 207
Hermite–Weber differential equation, 339
Hölder theorem, 349
holomorphic differential, 226, 231
holomorphic foliations, 616
holonomy transformation, 647, 648
homoclinic orbit, 403
homotopy factorization, 40
Hopf bifurcation, 54
Hukuhara–Kimura–Matuda theorem, 669
hull, 137, 143
Hutchinson model, 112
hyperbolic, 310, 367, 386, 405
hyperbolic distance, 311
hyperbolic periodic orbits, 381

icosahedral group, 98, 124
index of L, 21
indicial equation, 301
induction over orbit types, 23
intristic dimension, 16
invariant
– measure, 144
– set, 143
inverse growth problem, 320
irreducible representation, 12
irregular singular point, 596, 603
isolated, 94
– center, 77
isometric Hilbert G-representation, 17
isotropy, 11
isotypical component, 18
isotypical decomposition, 15, 18, 55
iterated order, 297, 306, 317, 318
iterated type, 319

Jacobian variety, 227

Korteweg–de Vries (K-dV) equation, 181
Kotani theory, 212, 215
Krein–Rutman theorem, 523
Kronecker flow, 144
Kronecker winding, 142, 144
Krylov–Bogoliubov construction, 145, 152

l-folding, 38
l-th isotypical crossing number, 63
$L_1([0,T],\mathbb{R}^n)$, 530
Lamé equation, 302, 303
lemma of the logarithmic derivative, 286, 351
Leray–Schauder twisted degree, 48
$\lfloor\cdot\rfloor$, 519
Li–Yorke chaos, 139, 179
lifting homeomorphism, 25
limit periodic, 144
limit point case, 188
linearization of diffeomorphism, 633, 658
Liouville-type frequencies, 250
Lipschitz condition, 518, 537, 539
local bifurcation
– $\Gamma \times S^1$-invariant, 116
– invariant, 7, 68, 78, 80, 88
– result, 97
local existence, 271, 273, 276
local index, 35
local solution, 336, 356
Lyapunov exponent, 146, 151, 175, 201, 202, 253

Malgrange–Sibuya theorem, 608
Malmquist, 325, 328, 332, 345
Malmquist theorem, 271,, 324, 326, 327, 330, 353, 354
map, 26, 27
Maple© input data, 102
Marcus and Moore disconjugacy, 171
Martinet–Ramis moduli, 642, 646, 650, 651, 654, 656
Martinet–Ramis theorem, 646
Melnikov function, 417
Millionscikov–Vinograd examples, 139, 175
Millionscikov–Vinograd type, 170
minimal flow, 143
minimal support, 191
modulus
– of quadrangle, 668
– of unnulus, 668
Mohon’ko, 322, 337, 339, 352
– lemma, 323
monodromic singular point, 623
monodromy
– operator, 598
– transformation, 648
movable singularities, 326
multiplicativity property, 47, 48

$\mathbb{N}$, 443
necessary condition
– for Hopf bifurcation, 58
– for the occurrence of Hopf bifurcation, 57
negative spectrum, 95, 101, 108, 118
Nevanlinna theory, 284–287, 307, 312, 319, 324, 328, 351, 352
– characteristic function, 285, 286, 323, 324, 345, 351, 353
– counting function, 285, 351, 352
– deficiency, 286, 288
– first main theorem, 285, 286, 351
– logarithmic derivative lemma, 292, 297, 352
– non-integrated counting function, 288, 351
– proximity function, 285, 351
– ramification index, 287, 337–340
– second main theorem, 286, 287, 310, 340, 341
Newlander–Nirenberg theorem, 666
Newton–Puiseux diagram, 290
node, 617
non-oscillatory, 308–310
non-trivial solutions, 87
nonautonomous dynamical systems, 135
nonlinear Schrödinger (NLS) equation, 181
normal, 27
normal form
– for diffeomorphisms, 634, 641, 649
– for linear system, 603
– for vector fields, 680
normal homotopy, 27
n species ecosystem, 112
numbers $n(L,H)$, 28
numerical shadowing, 368, 425

Ω-admissible, 26, 49
– homotopy, 26
$\Omega_{P,\sigma}$, 520
$\Omega(\beta)$, 557
orbit, 11, 143
– space, 11
– type, 11
orbital equivalence, 616, 642, 646, 649, 674
orbital linearization, 665
orbital normal form, 649, 656
order, 286, 288, 290–292, 294–296
Ortega and Tarallo examples, 165
oscillatory, 307, 308
Oseledets
– spectrum, 147, 151
– theory, 146

p-summability, 652
Painlevé differential equation, 271, 274, 275, 334
– Airy solutions, 337
– fifth Painlevé equation, 336, 337
– first Painlevé equation, 336
– first Painlevé hierarchy, 341

– fourth Painlevé equation, 336–338
– higher order Painlevé equations, 340
– rational solutions, 337, 339
– second Painlevé equation, 336, 338
– second Painlevé hierarchy, 341
– sixth Painlevé equation, 336, 337
– third Painlevé equation, 336–338
Painlevé equation, 335
Painlevé property, 334, 335, 340
parametrisation
– method of, 567
parametrized equivariant coincidence problem, 86
period matrix, 226
periodic, 294, 295, 302, 303, 331
– orbit, 367, 386
periodic-to-periodic homoclinic orbit, 367, 402, 412, 415
perturbed system, 367, 413, 416
Picard–Lindelöf theorem, 475
Poincaré map, 367, 382, 385, 386, 403, 405
Poincaré–Dulac normal form, 629
Poincaré–Dulac theorem, 601, 629
Poisson recurrence, 193, 194
principal solution, 171
projective flow, 139, 146, 154, 155, 197
proximal extension, 161, 168
property (τ, E), 510
proximal flow, 161
proximal pair, 161
pseudo orbit, 425
– homoclinic, 426
pseudo periodic orbit, 425

quasi-conformal map, 667
quasi-periodic flow, 142, 144
quasi-section, 258

$\mathbb{R}$, 443
$\mathbb{R}_+$, 443
$R^{\text{ed}}(L)$, 194
$r(A)$, 443
random dynamics, 135
ray of division, 606
$\text{RE}^{\pm}(L_\omega)$, 208, 209
reaction equation, 113
Recurrence Formula, 40, 43, 44
regular fundamental domain, 25
regular normal
– homotopy, 27
– map, 27
regular singular point, 596–598, 600
rescaling, 336
resolvent, 191
resonance, 601, 629
resonant diffeomorphism, 641, 649
resonant one-dimensional map, 649
resonant saddle, 630, 647, 656
resonant singular point, 617
result due to Frei, 296
Riccati differential equation, 271, 274, 275, 324, 330–333, 338, 339
Riccati equation, 196
Riemann inversion problem, 228
Riemann theta function, 228
robustness, 412
rotation number, 151, 152, 197, 202, 251
roughness theorem, 373

Sacker–Sell spectrum, 147
saddle, 617, 664
saddle–node, 617, 642, 656
Schwarzian derivative, 332
Schwarzian differential equation, 271, 332–334
Schwarzmann homomorphism, 141, 201
sequence
– equicontinuous, 474
– uniformly bounded, 473
shadow, 425
shooting method, 567
Siegel lemma, 350
singular point of Poincaré type, 629
singularity of the Fuchs type, 598
small function, 324
small meromorphic coefficients, 354
smooth G-vector bundle, 20
smoothness of the projections, 376
SNA (strange nonchaotic attractor), 175, 176
solutions of zero order, 344
space, 314
spectral matrix, 190, 191
spectral measure, 189
spectrum, 191
Splitting lemma, 40, 41
stable and unstable manifolds, 367, 386, 395, 396
stable fibre, 402
stochastic dynamical systems, 135
Stokes cocycle, 608
Stokes matrix, 607
Stokes operator, 607
Stokes sheaf, 607
strictly ergodic flow, 145
strong manifold, 643
strongly elliptic case, 167
Sturm–Liouville operator, 140, 184, 191
subordinate solution, 191
subrepresentation, 12
subset, 51

successive approximations, 453, 457, 470, 486, 488, 492, 498, 523, 540, 548, 557, 570
sufficient condition
– for Hopf bifurcation, 79, 81
– for symmetric Hopf bifurcation, 67
– for the occurrence of Hopf bifurcation, 58
Suspension Procedure, 40
symmetric configuration of transmission lines, 105
symmetric Hopf bifurcation, 66
– problem, 4
symmetric system of the Hutchinson model, 114

Takens prenormal form, 671, 681
telegrapher's equation, 103
theorem
– Arzelà–Ascoli, *see* Arzelà–Ascoli theorem
– Borsuk, *see* Borsuk theorem

Preface

Differential equations are widely used by mathematicians, physicists, engineers, biologists, chemists, and scientists who work in relevant fields. They encounter the use of differential equations in the study of Newton's law of cooling, Maxwell's equations, Newton's laws of motion, fluid dynamics equations, equations in plasma dynamics, equations in stellar dynamics, Hook's law, Schrödinger's equation, acoustic wave equation, equations in chemical kinetics, equations in thermodynamics, Einstein's equations for general relativity, population models, epidemics, and so on. For many years, the author has been encouraged by the graduate students at the University of Dayton to write a concise and reader-friendly book on the subject of advanced differential equations. So this book grew out of lecture notes that the author has been constantly revising and using for a graduate course in differential equations. The book should serve as a two-semester graduate textbook in exploring the theory and applications of ordinary differential equations and differential equations with delays. It is intended for students who have basic knowledge of ordinary differential equations and real analysis. While writing this book, the author tried to balance rigor and presenting the most difficult material in an elementary format by adopting easier and friendlier notations that make the book accessible to a wide audience. It was the author's main intention to provide many examples to illustrate the theory conveyed in the theorems. The author made every effort to include contemporary topics such as the use of *fixed point theory* in several places to prove the existence and uniqueness, various notions of stability, and the existence of positive periodic solutions on Banach spaces. What makes the book appealing and distinguished from other books is the addition of Chapters 8 and 9 on delay differential equations with advanced topics. The author is convinced that any student who completes the whole book, especially Chapters 8 and 9, should be ready to carry on with meaningful research in delay differential systems.

Much of the pedagogical and mathematical development of this book is influenced by the author's style of presentation. The literature on differential equations is vast and well established, and some of the ideas found their way into this book.

Since stability is the central part of this book, namely by the Lyapunov method, we must mention some history. Lyapunov functions are named after Alexander Lyapunov, a Russian mathematician, who in 1892 published his book *The General Problem of Stability of Motion*. Lyapunov was the first to consider the modifications necessary in nonlinear systems to the linear theory of stability based on linearizing near a point of equilibrium. His work, initially published in Russian and then translated to French, received little attention for many years. Interest in Lyapunov stability started suddenly during the Cold War period when his method was found to be applicable to the stability of aerospace guidance systems, which typically contain

Copyright Elsevier 2022

strong nonlinearities not treatable by other methods. More recently, the concept of the Lyapunov exponent related to Lyapunov's first method of discussing stability has received wide interest in connection with chaos theory.

Chapter 1 deals with various introductory topics, including variation of parameters formula, metric spaces, and Banach spaces.

In Chapter 2 we introduce Gronwall's inequality that we make use of to prove the uniqueness of solutions. We introduce theorems on the existence and uniqueness of solutions, their dependence on initial data, and their continuation on maximal interval.

In Chapter 3 we introduce systems of differential equations. We briefly discuss how the existence and uniqueness theorems of Chapter 2 are extended to suit systems. Then we develop the notion of the fundamental matrix as a solution and utilize it to write solutions of non-homogeneous systems so that they can be analyzed.

Stability theory is the central part of this book. Chapters 4–8 are totally devoted to stability. In Chapter 4 we are mainly concerned with the stability of linear systems via the variation of parameters. The chapter also includes a nice section of Floquet theory with its application to Mathieu's equation.

Chapters 5 and 6 are deeply devoted to the study of the stability of linear systems, near-linear systems, perturbed systems, autonomous systems in the plane, and stability by linearization. Chapter 5 is ended with the study of Hamiltonians and gradient systems. We begin Chapter 6 by looking at stability diagrams in scalar equations and move into the study of bifurcations as it naturally arises while looking at stability. Bifurcation occurs when the dynamics abruptly change as certain parameters move across certain values. We end Chapter 6 by considering stable and unstable manifolds, which then delves into the Hartman–Grobman theorem. The theorem says that the behavior of a dynamical system in the domain near a hyperbolic equilibrium point is qualitatively the same as the behavior of its linearization near this equilibrium point, where hyperbolicity means that no eigenvalue of the linearization has a zero real part.

Chapter 7 delves deeply into the stability of general systems using Lyapunov functions. We prove general theorems regarding the stability of autonomous and non-autonomous systems by assuming the existence of such Lyapunov function. We touch on the notion of ω-limit set and its correlation to Lyapunov functions. The chapter is concluded with a detailed discussion on exponential stability.

Chapter 8 is solely devoted to the study of delay differential equations. It contains recent development in the research of delay differential equations. We begin the chapter by pointing out how basic results from ordinary differential equations are easily extended to delay differential equations. We introduce the *method of steps* and show how to piece together a solution. The transition of moving from ordinary differential equations to delay differential equations was made simple through the extension of Lyapunov functions to Lyapunov functionals. Then we move on to

Copyright Elsevier 2022

a whole new concept, *fixed point theory*. The use of fixed point theory alleviates some of the difficulties that arise from the use of Lyapunov functionals when studying stability. Later on, we apply fixed point theory to the study of stability and the existence of positive periodic solutions of neutral differential equations and neutral Volterra integro-differential equations, respectively. We end the chapter with the use of Lyapunov functionals to obtain necessary conditions for the exponential stability of Volterra integro-differential equations with finite delay.

Chapter 9 deals with current research concerning the use of a *new variation of parameters formula*. The objective is to introduce a new method for inverting first-order ordinary differential equations with time-delay terms to obtain a new variation of parameters formula that we use to study the stability, boundedness, and periodicity of general equations in ordinary and delay differential equations.

A combination of Chapters 1–3, 6, and 7 can be used to deliver a course on nonlinear systems for engineers.

The author has not attempted to give the historical origin of the theory, except in very rare cases. This resulted in the situation that not every reference listed in References is mentioned in the text or the body of the book.

Exercises play an essential learning tool of the course and accompany each chapter. They range from routine calculations to solving more difficult problems to open-ended ones. Students must read the relevant material before attempting to do the exercises.

I am indebted to Dr. Mohamed Aburakhis, who fully developed all the codes for all the figures in the book. I like to thank the hundreds of graduate students at the University of Dayton whom the author taught for the last 20 years and who helped the polishing and refining of the lecture notes, most of which have become this book.

A heartfelt appreciation to Jeff Hemmelgarn from the University of Dayton for carefully reading the whole book and pointing out many typos.

CHAPTER

Preliminaries and Banach spaces

1

We briefly discuss basic topics of ordinary differential equations and provide examples that illustrate the need for a comprehensive and systematic theory of differential equations. In addition, we introduce metrics and Banach spaces, which we will use throughout the book.

1.1 Preliminaries

Let $\mathbb{R}$ denote the set of real numbers, let I be an interval in $\mathbb{R}$, and consider a function $x : I \to \mathbb{R}$. We say the function x has a derivative at a point $t^* \in I$ if the limit

$$\lim_{t\in I,\, t\to t^*} \frac{x(t) - x(t^*)}{t - t^*}$$

exists as a finite number. In this case, we adopt the notation

$$x'(t^*) = \lim_{t\in I,\, t\to t^*} \frac{x(t) - x(t^*)}{t - t^*},$$

where $x'(t^*)$ is the instantaneous rate of change of the function x at t^*. If t^* is one of the endpoints of the interval I, then the above definition of derivative becomes that of a one-sided derivative. If $x'(t^*)$ exists at every point $t^* \in I$, then we say that x is differentiable on I and write $x'(t)$. Throughout the book, we might use $\frac{dx}{dt}$ to indicate $x'(t)$. Similarly, if $x'(t)$ has a derivative function, then we call it the second derivative of the function $x(t)$ and denote it by $x''(t)$. For higher-order derivatives, we use the notations

$$x'''(t), x^{(4)}(t), \dots, x^{(n)}(t), \ \text{ or } \ \frac{d^n x}{dt^n}.$$

The *order of a differential equation* is defined by the highest derivative present in the equation. An *nth-order ordinary differential equation* is a functional relation of the form

$$F\big(t, x, \frac{dx}{dt}, \frac{d^2x}{dt^2}, \frac{d^3x}{dt^3}, \dots, \frac{d^nx}{dt^n}\big) = 0,\ t \in \mathbb{R} \tag{1.1.1}$$

between the independent variable t and the dependent variable x, and its derivatives

$$\frac{dx}{dt}, \frac{d^2x}{dt^2}, \frac{d^3x}{dt^3}, ..., \frac{d^nx}{dt^n}.$$

Loosely speaking, by a solution of (1.1.1) on an interval I, we mean a function $x(t) = \varphi(t)$ such that

$$F\big(t, \varphi(t), \varphi'(t), \dots, \varphi^{(n)}(t)\big)$$

is defined for all $t \in I$ and

$$F\big(t, \varphi(t), \varphi'(t), \dots, \varphi^{(n)}(t)\big) = 0$$

for all $t \in I$. If we require, for some initial time $t_0 \in \mathbb{R}$, a solution $x(t)$ to satisfy the initial conditions

$$x(t_0) = a_0, \ \frac{dx}{dt}(t_0) = a_1, \ \frac{d^2x}{dt^2}(t_0) = a_2, \ \dots, \ \frac{d^{n-1}x}{dt^{n-1}}(t_0) = a_{n-1}, \tag{1.1.2}$$

for constants a_i, $i = 0, 1, 2, ..., n-1$, then (1.1.1) along with (1.1.2) is called an initial value problem (IVP).

Following the notation of (1.1.1), a first-order differential equation takes the form

$$F\big(t, x, \frac{dx}{dt}\big) = 0.$$

Hence, if we assume that we can solve for $\dfrac{dx}{dt}$, then we have

$$x'(t) = f(t, x)$$

for some function f that satisfies certain continuity conditions.

Let $x : I \to \mathbb{R}$ be a function. A differentiable function $z : I \to \mathbb{R}$ is called an *antiderivative* of the function x on the interval I if

$$z'(t) = x(t) \ \text{ for all } \ t \in I.$$

The set of all antiderivatives of x is denoted by

$$\int x(t)dt$$

and called the indefinite integral of the function x. When we calculate the indefinite integral $\int t^2 dt$, we in fact solve the first-order differential equation $x'(t) = t^2$. The family of its solutions is given by $t^3/3 + c$, where c is any constant. Thus we may write the solution as $x(t) = t^3/3 + c$, which is a one-parameter family of solutions, the same as the family of all the antiderivatives of t^3. Now, if we impose an initial condition on the differential equation, say $x(t_0) = x_0$, for some initial time

Copyright Elsevier 2022

t_0 and real number x_0, then the constant c is uniquely determined by the relation $x_0 = t_0^3/3 + c$. In this case the differential equation has the unique solution given by $x(t) = t^3/3 + x_0 - t_0^3/3$. However, without imposing the condition $x(t_0) = x_0$, the differential equation would have infinitely many solutions given by $x(t) = t^3/3 + c$.

Differential equations play an important role in modeling the behavior of physical systems such as falling bodies, vibration of a mass on a spring, and swinging pendulum. To illustrate the need for the theoretical study of differential equations and in particular nonlinear ones, we examine a few examples.

Consider the first-order differential equation

$$x'(t) = h(t)g(x), \ x(t_0) = x_0, \ t \geq t_0,$$

where $h, g : \mathbb{R} \to \mathbb{R}$ are continuous.

1. If $g(x_0) = 0$, then $x(t) = x_0$ is a solution.
2. In a region where $g(x) \neq 0$, we can divide by $g(x)$ so that

$$\frac{x'(t)}{g(x(t))} = h(t).$$

Separating the variables and then integrating both sides from t_0 to t give

$$\int_{t_0}^{t} \frac{x'(s)ds}{g(x(s))} = \int_{t_0}^{t} h(s)ds.$$

Using the transformation $u = x(s)$ with $x(t_0) = x_0$, we arrive at

$$\int_{x_0}^{x(t)} \frac{du}{g(u)} = \int_{t_0}^{t} h(s)ds.$$

If for some function G, we have $\frac{dG}{dx} = \frac{1}{g}$, then the above expression implies that

$$G(x(t)) - G(x(t_0)) = \int_{t_0}^{t} h(s)ds$$

or

$$x(t) = G^{-1}\Big(G(x_0) + \int_{t_0}^{t} h(s)ds\Big),$$

provided that the inverse of G exists. Note that the right side of the above expression depends on the initial time t_0 and the initial value x_0. Therefore to emphasize the dependence of solutions on the initial data, we may write a solution $x(t)$ in the form $x(t) = x(t, t_0, x_0)$.

Copyright Elsevier 2022

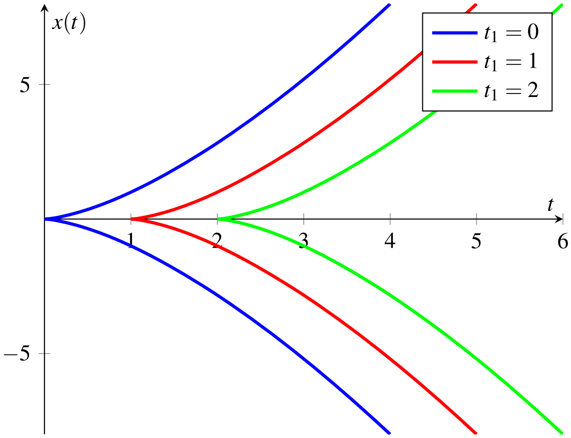

FIGURE 1.1

This example shows infinitely many solutions.

In the next example, we illustrate the existence of more than one solution. Consider the differential equation

$$x'(t) = \frac{3}{2}x^{1/3}(t),\ x(0) = 0,\ t \in \mathbb{R}.$$

It is clear that $x(t) = 0$ is a solution. Hence we may consider a solution $x_1(t) = 0$ and let

$$x_2(t) = \begin{cases} 0 & \text{for } t \leq 0, \\ t^{3/2} & \text{for } t > 0, \end{cases}$$

which is also a continuous and differentiable solution. Likewise, for $t_1 > 0$, we have

$$x_3(t) = \begin{cases} 0 & \text{for } t \leq t_1, \\ (t - t_1)^{3/2} & \text{for } t > t_1. \end{cases}$$

Continuing in this way, we see that the differential equation has infinitely many solutions. Similarly, if x is a solution, then $-x$ is also a solution (see Fig. 1.1).

In the next example, we show that solutions may escape (become unbounded) in finite time. The differential equation

$$x'(t) = x^3(t),\ x(t_0) = x_0 > 0,\ t \geq t_0$$

has the solution

$$x(t) = \sqrt{\frac{1}{\frac{1}{x_0^2} + 2(t_0 - t)}}.$$

Copyright Elsevier 2022

We can easily see that the solution is only valid for $t < t_0 + \dfrac{1}{2x_0^2}$ and becomes unbounded (escapes) as t approaches $t_0 + \frac{1}{2x_0^2}$ from the left.

The most important application in engineering problems is Newton's law

$$m\frac{d^2x(t)}{dt^2} = F[t, x(t), \frac{dx(t)}{dt}]$$

for the position $x(t)$ of a particle with mass m acted on by a force F, which may be a function to time t, the position $x(t)$, and the velocity $\frac{dx(t)}{dt}$. For example, if the force is only due to gravity, then we have the second-order differential equation

$$m\frac{d^2x(t)}{dt^2} = -mg,$$

which has the solution

$$x(t) = -\frac{1}{2}gt^2 + c_1t + c_2,$$

where c_1 and c_2 are constants that can be uniquely determined by specifying the position and velocity of the particle at some instant of time.

In the next example, we consider the problem of *leaky bucket*.

Example 1.1. We have a bucket with no water flowing into it and having a hole in the bottom. If Q is the volumetric flow rate, then $Q_{\text{in}} - Q_{\text{out}} = Q_{\text{stored}}$. Since $Q_{\text{in}} = 0$, we obtain $Q_{\text{stored}} = -Q_{\text{out}}$. Let $h(t)$ be the height of the water in the bucket at time t, and assume that the initial height at time $t = 0$ is h_0. Let $v(t)$ be the velocity of the leaked water (flow velocity). The volumetric flow rate Q_{stored} can be calculated by multiplying the velocity by the area of the bucket, that is, $Q_{\text{stored}} = A_{\text{bucket}}\frac{dh(t)}{dt}$. Similarly, Q_{out} is the flow velocity multiplied by the area of the hole A_{hole}. It follows that $Q_{\text{out}} = A_{\text{hole}}v(t)$. For fluids of height $h(t)$, the velocity of water coming out at the bottom is $v(t) = \sqrt{2gh(t)}$. By rearranging the terms, we arrive at the first-order differential equation in h given by

$$\frac{dh(t)}{dt} = -k\sqrt{h}, \quad h(0) = h_0, \tag{1.1.3}$$

where $k = \dfrac{A_{\text{hole}}}{A_{\text{bucket}}}\sqrt{2g} > 0$. By separating the variables in (1.1.3) and then integrating, we arrive at the solution

$$h(t) = \left(\sqrt{h_0} - \frac{kt}{2}\right)^2. \tag{1.1.4}$$

Note that the solution $h(t)$ given by (1.1.4) decreases from the initial height h_0. Moreover, at time $t^* = \frac{2\sqrt{h_0}}{k}$, the water is completely drained (by gravity), $h(t^*) = 0$, and

Copyright Elsevier 2022

the bucket will remain empty or the height will remain zero after $t^* = \frac{2\sqrt{h_0}}{k}$. Therefore we may write the solution as

$$h(t,0,h_0) = \begin{cases} \left(\sqrt{h_0} - \frac{kt}{2}\right)^2, & 0 \le t \le \frac{2\sqrt{h_0}}{k}, \\ 0, & t > \frac{2\sqrt{h_0}}{k}. \end{cases}$$

Another interesting application is the projectile problem that we analyze in the next section.

1.2 Escape velocity

Let M and R be the mass and radius of the Earth, respectively. We are interested in finding the smallest initial velocity for a mass m to exit the Earth's gravitational field, the so-called *escape velocity*. We assume that no external forces are acting on the system other than the gravitational force. Newton's universal gravitational law states that the force between two massive bodies is proportional to the product of the masses and inversely proportional to the square of the distance between them, where the mass of each body can be considered as concentrated at its center. For a mass m with position x above the surface of the Earth, the force F on the mass is given by

$$F = -G\frac{Mm}{(R+x)^2},$$

where G is the proportionality constant in the universal gravitational law. The minus sign means the force on the mass m points in the direction of decreasing x. By Newton's second law, force $F = m\frac{d^2x}{dt^2}$ (mass times acceleration). When $x = 0$, that is, at the Earth's surface, the gravitational force equals $-mg$, where g is the gravitational constant. Therefore

$$\frac{GM}{R^2} = g, \quad g \approx 9.8\,\mathrm{m/s}^2.$$

We have the second-order differential equation

$$\begin{aligned} \frac{d^2x}{dt^2} &= -G\frac{M}{(R+x)^2} \\ &= -\frac{g}{(1+\frac{x}{R})^2}, \end{aligned} \tag{1.2.1}$$

where the radius of the Earth is known to be $R \approx 6350\,\mathrm{km}$. We transform Eq. (1.2.1) into a first-order differential equation in terms of the velocity v by noting that $\frac{d^2x}{dt^2} = \frac{dv}{dt}$. If we write $v(t) = v(x(t))$, that is, considering the velocity of the mass m as a

Copyright Elsevier 2022

function of its distance above the Earth. Then using the chain rule, we have

$$\begin{aligned}\frac{dv}{dt} &= \frac{dv}{dx}\frac{dx}{dt} \\ &= v\frac{dv}{dx},\end{aligned}$$

since $v = \frac{dx}{dt}$. As a consequence, (1.2.1) becomes the first-order differential equation

$$\frac{dv}{dx} = -\frac{g}{(1+\frac{x}{R})^2}\frac{1}{v}.$$

Suppose the mass is shot vertically from the Earth's surface with initial velocity $v(x=0) = v_0$. Separating the variables and integrating both sides, we obtain

$$\int v dv = -g\int \frac{dx}{(1+\frac{x}{R})^2},$$

which gives

$$\frac{v^2}{2} = \frac{gR^2}{R+x} + c$$

for some constant c. Using the initial velocity condition, we find

$$c = -gR + \frac{v_0^2}{2}.$$

Substituting c back into the solution and simplifying, we arrive at the solution

$$v^2 = v_0^2 - \frac{gRx}{R+x}.$$

The escape velocity is defined as the minimum initial velocity v_0, such that the mass can escape to infinity. Therefore $v_0 = v_{\text{escape}}$ when $v \to 0$ as $x \to \infty$. Taking the limit, we have

$$0 = v_0^2 - \lim_{x\to\infty}\frac{gRx}{R+x} = v_0^2 - 2gR,$$

or

$$v_{\text{escape}}^2 = 2gR.$$

With $R \approx 6350\,\text{km}$ and $g = 127{,}008\,\text{km/h}^2$, we get $v_{\text{escape}} = \sqrt{2gR} \approx 40{,}000\,\text{km/h}$. In contrast, the muzzle velocity of a modern high-performance rifle is 4300 km/h, which is not enough for a bullet shot into the sky to escape from Earth's gravity.

Now we formally attempt to qualitatively analyze differential equations.

Copyright Elsevier 2022

Definition 1.2.1. Let D be an open subset of $\mathbb{R}^2$, and let $f : D \to \mathbb{R}$ be a continuous function. Let $(t_0, x_0) \in D$. We say that $x(t) = x(t, t_0, x_0)$ is a solution of

$$x' = f(t, x), \quad x(t_0) = x_0, \tag{1.2.2}$$

on an interval I if $t_0 \in I$, $x : I \to \mathbb{R}$ is differentiable, $(t, x(t)) \in D$ for $t \in I$, $x'(t) = f(t, x(t))$ for $t \in I$, and $x(t_0) = x_0$.

Definition 1.2.2. A solution $x(t)$ of (1.2.2) is said to be bounded on the interval $I = [0, \infty)$ if for any $t_0 \in [0, \infty)$ and $r > 0$, there exists a *positive number* $\alpha(t_0, r)$ depending on t_0 and r such that $|x(t, t_0, x_0)| \leq \alpha(t_0, r)$ for all $t \geq t_0$ and x_0 such that $|x_0| < r$. It is uniformly bounded if α is independent of the initial time t_0.

Definition 1.2.3. Let $x(t)$ and $y(t)$ be solutions of (1.2.2) with respect to initial conditions x_0 and y_0, respectively. The solution $x(t)$ is then said to be stable if for every $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon, t_0) > 0$ such that

$$|x(t) - y(t)| < \varepsilon \text{ whenever } |x_0 - y_0| < \delta.$$

Consider the linear differential equation

$$x'(t) = 1, \; x(t_0) = x_0. \tag{1.2.3}$$

It is easy to check that $x(t) = x_0 + (t - t_0)$ is the solution of (1.2.3). If $y(t)$ is another solution with $y(t_0) = y_0$, then we have $y(t) = y_0 + (t - t_0)$. For any $\varepsilon > 0$, let $\delta = \varepsilon$. Then

$$|x(t) - y(t)| = |x_0 + (t - t_0) - y_0 - (t - t_0)| = |x_0 - y_0| < \varepsilon$$

whenever $|x_0 - y_0| < \delta$. Hence the solution $x(t)$ is stable but clearly unbounded. This simple example shows that the notion of a solution being unbounded does not automatically imply that the same solution is unstable with respect to another solution starting at a different initial point. In Chapters 6 and 7 we will discuss boundedness and stability in more detail. The previous examples illustrate the need for a coherent theory for addressing the following issues:

1. Existence and uniqueness.
2. Boundedness and stability.
3. The dependence of solutions on the initial data.

1.3 Applications to epidemics

The *law of mass action* is a useful concept that describes the behavior of a system that consists of many interacting parts, such as molecules, that react with each other, or viruses that are passed along from a population of infected individuals to non-immune ones. The law of mass action was first derived for chemical systems but

Copyright Elsevier 2022

subsequently found wide use in epidemiology and ecology. To describe the law of mass action, we assume that m substances $s_1, s_2, \dots, s_m$ together form a product with concentration p. Then the law of mass action states that $\frac{dp}{dt}$ is proportional to the product of the m concentrations s_i, $i = 1, \dots, m$, that is,

$$\frac{dp}{dt} = k s_1 s_2 \dots s_m.$$

Suppose we have a homogeneous population of fixed size divided into two groups. Those who have the disease are called infective, and those who do not have the disease are called susceptible. Let $S = S(t)$ be the susceptible portion of the population, and let $I = I(t)$ be the infective portion. Then by assumption, we may normalize the population and have $S + I = 1$. We further assume that the dynamics of this epidemic satisfies the law of mass action. Hence, for positive constant λ, we have the nonlinear differential equation

$$I'(t) = \lambda S I. \tag{1.3.1}$$

Let $I(0) = I_0$, $0 < I(0) < 1$, be a given initial condition. By substituting $S = 1 - I$ into (1.3.1) it follows that

$$I'(t) = \lambda I(1 - I), \quad I(0) = I_0. \tag{1.3.2}$$

If we can solve (1.3.2) for $I(t)$, then $S(t)$ can be found from the relation $I + S = 1$. We separate the variables in (1.3.2) and obtain

$$\frac{dI}{I(1-I)} = \lambda dt.$$

Using partial fraction on the left side of the equation and then integrating both sides yield

$$\text{Ln}|I| - \text{Ln}|1 - I| = \lambda t + c,$$

or for positive constant c_1, we have

$$I(t) = \frac{c_1 e^{\lambda t}}{1 + c_1 e^{\lambda t}}.$$

Applying $I(0) = I_0$ gives the solution

$$I(t) = \frac{I_0 e^{\lambda t}}{1 - I_0 + I_0 e^{\lambda t}}. \tag{1.3.3}$$

Now for $0 < I(0) < 1$, the solution given by (1.3.3) is increasing with time as expected. Moreover, using L'Hospital's rule, we have

$$\lim_{t \to \infty} I(t) = \lim_{t \to \infty} \frac{I_0 e^{\lambda t}}{1 - I_0 + I_0 e^{\lambda t}} = 1.$$

Copyright Elsevier 2022

Hence the infection will grow, and everyone in the population will eventually get infected.

1.4 Metrics and Banach spaces

This section is devoted to introductory materials related to Cauchy sequences, metric spaces, contraction, compactness, contraction mapping principle, and Banach spaces. Materials in this section will be of use in several places of the book, especially in Chapters 2, 8, and 9. Throughout the book, by $C(I, \mathbb{R}^n)$, we denote the space of all continuous functions $f : I \to \mathbb{R}^n$ on an interval I, possibly infinite.

Definition 1.4.1. A pair (E, ρ) is a metric space if E is a set and $\rho : E \times E \to [0, \infty)$ such that for all y, z, and u in E, we have

(a) $\rho(y, z) \geq 0$, $\rho(y, y) = 0$, and $\rho(y, z) = 0$ implies $y = z$;
(b) $\rho(y, z) = \rho(z, y)$; and
(c) $\rho(y, z) \leq \rho(y, u) + \rho(u, z)$.

The next definition is concerned with Cauchy sequences.

Definition 1.4.2. (Cauchy sequence) A sequence $\{x_n\} \subseteq E$ is a Cauchy sequence if for each $\varepsilon > 0$, there exists $N \in \mathbb{N}$ such that $n, m > N \implies \rho(x_n, x_m) < \varepsilon$.

Complete metric spaces play a major role when showing that a fixed point belongs to the metric space of interest.

Definition 1.4.3. (Completeness of metric space) A metric space (E, ρ) is said to be complete if every Cauchy sequence in E converges to a point in E.

Definition 1.4.4. A set L in a metric space (E, ρ) is compact if each sequence in L has a subsequence with a limit in L.

Definition 1.4.5. Let $\{f_n\}$ be a sequence of real functions with $f_n : [a, b] \to \mathbb{R}$.

1. $\{f_n\}$ is uniformly bounded on $[a, b]$ if there exists $M > 0$ such that $|f_n(t)| \leq M$ for all $n \in \mathbb{N}$ and $t \in [a, b]$.
2. $\{f_n\}$ is equicontinuous at t_0 if for each $\varepsilon > 0$, there exists $\delta > 0$ such that for all $n \in \mathbb{N}$, if $t \in [a, b]$ and $|t_0 - t| < \delta$, then $|f_n(t_0) - f_n(t)| < \varepsilon$. Also, $\{f_n\}$ is equicontinuous if $\{f_n\}$ is equicontinuous at each $t_0 \in [a, b]$.
3. $\{f_n\}$ is uniformly equicontinuous if for each $\varepsilon > 0$, there exists $\delta > 0$ such that for all $n \in \mathbb{N}$, if $t_1, t_2 \in [a, b]$ and $|t_1 - t_2| < \delta$, then $|f_n(t_1) - f_n(t_2)| < \varepsilon$.

It is easy to see that $\{f_n\} = \{x^n\}$ is not an equicontinuous sequence of functions on $[0, 1]$ but each f_n is uniformly continuous.

Proposition 1.1. *[Cauchy criterion for uniform convergence] If $\{F_n\}$ is a sequence of bounded functions that is Cauchy in the uniform norm, then $\{F_n\}$ converges uniformly.*

Copyright Elsevier 2022

Definition 1.4.6. A real-valued function f defined on $E \subseteq \mathbb{R}$ is said to be Lipschitz continuous with Lipschitz constant K if $|f(x) - f(y)| \leq K|x - y|$ for all $x, y \in E$.

It is easy to see that the function $f(x) = x^2$ is not Lipschitz on $\mathbb{R}$. This is due to the fact that for any x and y in $\mathbb{R}$, we have that $f(x) - f(y) = |x^2 - y^2| = |x + y||x - y|$, and so there is no constant K such that $|x^2 - y^2| \leq K|x - y|$. Definition 1.4.6 implies that f is globally Lipschitz since the constant K is uniform for all x and y in $\mathbb{R}$.

Remark 1.1. It is an easy exercise that a Lipschitz continuous function is uniformly continuous. Also, if each f_n in a sequence of functions $\{f_n\}$ has the same Lipschitz constant, then the sequence is uniformly equicontinuous.

Lemma 1.1. *If $\{f_n\}$ is an equicontinuous sequence of functions on a closed bounded interval, then $\{f_n\}$ is uniformly equicontinuous.*

Proof. Suppose $\{f_n\}$ is equicontinuous on $[a, b]$. Let $\varepsilon > 0$. For each $x \in K$, let $\delta_x > 0$ be such that $|y - x| < \delta_x \implies |f_n(x) - f_n(y)| < \varepsilon/2$ for all $n \in \mathbb{N}$. The collection $\{B(x, \delta_x/2) : x \in [a, b]\}$ is an open cover of $[a, b]$, so it has a finite subcover $\{B(x_i, \delta_{x_i}/2) : i = 1, \ldots, k\}$. Let $\delta = \min\{\delta_{x_i}/2 : i = 1, \ldots, k\}$. Then, if $x, y \in [a, b]$ with $|x - y| < \delta$, then there is some i with $x \in B(x_i, \delta_{x_i}/2)$. Since $|x - y| < \delta \leq \delta_{x_i}/2$, we have $|x_i - y| \leq |x_i - x| + |x - y| < \delta_{x_i}/2 + \delta_{x_i}/2 = \delta_{x_i}$. Hence $|x_i - y| < \delta_{x_i}$ and $|x_i - x| < \delta_{x_i}$. So, for any $n \in \mathbb{N}$, we have $|f_n(x) - f_n(y)| \leq |f_n(x) - f_n(x_i)| + |f_n(x_i) - f_n(y)| < \varepsilon/2 + \varepsilon/2 = \varepsilon$. So $\{f_n\}$ is uniformly equicontinuous. ☐

The next theorem gives us the main method of proving compactness in the spaces we are interested in.

Theorem 1.4.1. *[Ascoli–Arzelà] If $\{f_n(t)\}$ is a uniformly bounded and equicontinuous sequence of real-valued functions on an interval $[a, b]$, then there is a subsequence that converges uniformly on $[a, b]$ to a continuous function.*

Proof. Since $\{f_n(t)\}$ is equicontinuous on $[a, b]$, by Lemma (1.1) $\{f_n(t)\}$ is uniformly equicontinuous. Let $t_1, t_2, \ldots$ be a listing of the rational numbers in $[a, b]$ (note that the set of rational numbers is countable, so this enumeration is possible). The sequence $\{f_n(t_1)\}_{n=1}^{\infty}$ is a bounded sequence of real numbers (since $\{f_n\}$ is uniformly bounded), so it has a subsequence $\{f_{n_k}(t_1)\}$ converging to a number, which we denote $\phi(t_1)$. It will be more convenient to represent this subsequence without subsubscripts, so we write f_k^1 for f_{n_k} and switch the index from k to n. So the subsequence is written as $\{f_n^1(t_1)\}_{n=1}^{\infty}$. Now, the sequence $\{f_n^1(t_2)\}$ is bounded, so it has a convergent subsequence, say $\{f_n^2(t_2)\}$, with limit $\phi(t_2)$. We continue in this way obtaining a sequence of sequences $\{f_n^m(t)\}_{n=1}^{\infty}$ (one sequence for each m), each of which is a subsequence of the previous one. Furthermore, we have $f_n^m(t_m) \to \phi(t_m)$ as $n \to \infty$ for each $m \in \mathbb{N}$. Now, consider the "diagonal" functions defined $F_k(t) = f_k^k(t)$. Since $f_n^m(t_m) \to \phi(t_m)$, it follows that $F_r(t_m) \to \phi(t_m)$ as $r \to \infty$ for each $m \in \mathbb{N}$ (in other words, the sequence $\{F_r(t)\}$ converges pointwise at

Copyright Elsevier 2022

each t_m). We now show that $\{F_k(t)\}$ converges uniformly on $[a,b]$ by showing that it is Cauchy in the uniform norm. Let $\varepsilon > 0$, and let $\delta > 0$ be as in the definition of uniformly equicontinuous for $\{f_n(t)\}$ applied with $\varepsilon/3$. Divide $[a,b]$ into p intervals, where $p > \frac{b-a}{\delta}$. Let ξ_j be a rational number in the jth interval for $j = 1, \dots, p$. Recall that $\{F_r(t)\}$ converges at each of the points ξ_j, since they are rational numbers. So, for each j, there is $M_j \in \mathbb{N}$ such that $|F_r(\xi_j) - F_s(\xi_j)| < \varepsilon/3$ whenever $r, s > M_j$. Let $M = \max\{M_j : j = 1, \dots, p\}$. If $t \in [a,b]$, then it is in one of the p intervals, say the jth. So $|t - \xi_j| < \delta$, and thus $|f_r^r(t) - f_r^r(\xi_j)| = |F_r(t) - F_r(\xi_j)| < \varepsilon/3$ for every r. Also, if $r, s > M$, then $|F_r(\xi_j) - F_s(\xi_j)| < \varepsilon/3$ (since M is the maximum of the M_i). So for $r, s > M$, we have

$$\begin{aligned}
|F_r(t) - F_s(t)| &= |F_r(t) - F_r(\xi_j) + F_r(\xi_j) - F_s(\xi_j) + F_s(\xi_j) - F_s(t)| \\
&\le |F_r(t) - F_r(\xi_j)| + |F_r(\xi_j) - F_s(\xi_j)| + |F_s(\xi_j) - F_s(t)| \\
&\le \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon.
\end{aligned}$$

By the Cauchy criterion for convergence, the sequence $\{F_r(t)\}$ converges uniformly on $[a,b]$. Since each $F_r(t)$ is continuous, the limit function $\phi(t)$ is also continuous. ☐

Remark 1.2. The Ascoli–Arzelà theorem can be generalized to a sequence of functions from $[a,b]$ to $\mathbb{R}^n$. Apply the Ascoli–Arzelà theorem to the first coordinate function to get a uniformly convergent subsequence. Then apply the theorem again, this time to the corresponding subsequence of functions restricted to the second coordinate, getting a subsubsequence, and so on.

The next criterion, known as the Weierstrass M-test plays an important role in showing the existence of solutions.

Lemma 1.2. *(Weierstrass M-test) Let $\{f_n\}$ be a sequence of functions defined on a set E. Suppose that for all $n = 1, \dots,$ there is a constant M_n such that $|f_n(t)| \le M_n$ for all $t \in E$. If*

$$\sum_{n=1}^{\infty} M_n < \infty, \ \ \textit{then} \ \ \sum_{n=1}^{\infty} f_n(t)$$

converges absolutely and uniformly on the E.

We remark that the Weierstrass M-test can be easily generalized if the domain of the sequence of functions is a subset of Banach space endowed with an appropriate norm.

Here is an example of the Weierstrass M-test.

Example 1.2. For $n = 1, 2, \dots,$ define the sequence of functions $\{f_n\}$ on $\mathbb{R}$ by $f_n(t) = \dfrac{1}{t^2 + n^2}$. Then $|f_n(t)| = |\dfrac{1}{t^2+n^2}| \le \dfrac{1}{n^2} := M_n$ for all $t \in \mathbb{R}$ and $n \ge 1$. Since

Copyright Elsevier 2022

the series $\sum_{n=1}^{\infty}\frac{1}{n^2}$ converges, by the Weierstrass M-test the series $\sum_{n=1}^{\infty}\frac{1}{t^2+n^2}$ converges uniformly on $\mathbb{R}$. Moreover, as each term of the series is continuous and the convergence is uniform, the sum function is also continuous. (As the uniform limit of continuous functions is continuous.)

Here is another example with a simple twist to it.

Example 1.3. We prove that the series

$$\sum_{n=1}^{\infty}\frac{n^2+x^4}{n^4+x^2}$$

converges to a continuous function $f:\mathbb{R}\to\mathbb{R}$.

Let c be a positive constant. Then for all $x\in[-c,c]$, we have that

$$\left|\frac{n^2+x^4}{n^4+x^2}\right|\le\frac{n^2+x^4}{n^4}\le\frac{1}{n^2}+\frac{c^4}{n^4}:=M_n.$$

On the other hand, the series

$$\sum_{n=1}^{\infty}M_n=\sum_{n=1}^{\infty}\frac{1}{n^2}+c^4\sum_{n=1}^{\infty}\frac{1}{n^4}$$

converges, so Weierstrass M-test implies that the series converges uniformly to a function f on the bounded interval $[-c,c]$. Each term in the series is continuous and since the uniform limit of continuous functions is continuous, the limit function f is continuous on $[-c,c]$ for every $c>0$. Now since every $x\in\mathbb{R}$ lies in such an interval for sufficiently large c, it follows that f is continuous on $\mathbb{R}$. Note that the series does not converge uniformly on $\mathbb{R}$, so we cannot use the argument that the sum is continuous on $\mathbb{R}$ because the series converges uniformly on $\mathbb{R}$.

Banach spaces form an important class of metric spaces. We now define Banach spaces in several steps.

Definition 1.4.7. A triple $(V,+,\cdot)$ is said to be a linear (or vector) space over a field F if V is a set and the following are true.

1. Properties of $+$
   - **a.** $+$ is a function from $V\times V$ to V. Outputs are denoted $x+y$.
   - **b.** for all $x,y\in V$, $x+y=y+x$ ($+$ is commutative).
   - **c.** for all $x,y,w\in V$, $x+(y+w)=(x+y)+w$ ($+$ is associative).
   - **d.** there is a unique element of V, which we denote 0, such that for all $x\in V$, $0+x=x+0=x$ (additive identity).
   - **e.** for each $x\in V$, there is a unique element of V, which we denote $-x$, such that $x+(-x)=-x+x=0$ (additive inverse).

Copyright Elsevier 2022

2. Scalar multiplication
  a. $\cdot$ is a function from $F \times V$ to V. Outputs are denoted $\alpha \cdot x$ or αx.
  b. for all $\alpha, \beta \in F$ and $x \in V$, $\alpha(\beta x) = (\alpha\beta)x$.
  c. for all $x \in V$, $1 \cdot x = x$.
  d. for all $\alpha, \beta \in F$ and $x \in V$, $(\alpha + \beta)x = \alpha x + \beta x$.
  e. for all $\alpha \in F$ and $x, y \in V$, $\alpha(x + y) = \alpha x + \alpha y$.

Commonly, the real numbers and complex numbers are fields in the above definition. For our purposes, we only consider the field of real numbers $F = \mathbb{R}$.

Definition 1.4.8. (Normed spaces) A vector space $(V, +, \cdot)$ is a *normed space* if for each $x \in V$, there is a nonnegative real number $\|x\|$, called the *norm* of x, such that for all $x, y \in V$ and $\alpha \in \mathbb{R}$,

1. $\|x\| = 0$ if and only if $x = 0$,
2. $\|\alpha x\| = |\alpha|\|x\|$,
3. $\|x + y\| \leq \|x\| + \|y\|$.

Remark 1.3. A norm on a vector space always defines a metric $\rho(x, y) = \|x - y\|$ on the vector space. Given a metric ρ defined on a vector space, it is tempting to define $\|v\| = \rho(v, 0)$. But this is not always a norm.

Definition 1.4.9. A Banach space is a complete normed vector space, that is, a vector space $(X, +, \cdot)$ with norm $\|\cdot\|$ for which the metric $\rho(x, y) = \|x - y\|$ is complete.

Example 1.4. The space $(\mathbb{R}^n, +, \cdot)$ over the field $\mathbb{R}$ is a vector space (with the usual vector addition $+$ and scalar multiplication $\cdot$), and there are many suitable norms for it. For example, if $x = (x_1, x_2, \ldots, x_n)$, then

1. $\|x\| = \max_{1 \leq i \leq n} |x_i|$,
2. $\|x\| = \sqrt{\sum_{i=1}^{n} x_i^2}$,
3. $\|x\| = \sum_{i=1}^{n} |x_i|$,
4. $\|x\|_p = \left(\sum_{i=1}^{n} |x_i|^p\right)^{1/p}$, $p \geq 1$

are all suitable norms. Norm 2 is the Euclidean norm: the norm of a vector is its Euclidean distance to the zero vector, and the metric defined from this norm is the usual Euclidean metric. Norm 3 generates the "taxi-cab" metric on $\mathbb{R}^2$, and Norm 4 is the l^p norm.

Throughout the book, it should cause no confusion to use $|\cdot|$ instead of $||\cdot||$ to denote a particular norm.

Remark 1.4. Consider the vector space $(\mathbb{R}^n, +, \cdot)$ as a metric space with its metric defined by $\rho(x, y) = \|x - y\|$, where $\|\cdot\|$ is any of the norms in Example 1.4. The

Copyright Elsevier 2022

completeness of this metric space comes directly from the completeness of $\mathbb{R}$, and hence $(\mathbb{R}^n, \|\cdot\|)$ is a Banach space.

Remark 1.5. In the Euclidean space $\mathbb{R}^n$, compactness is equivalent to closedness and boundedness (Heine–Borel theorem). In fact, the metrics generated from any of the norms in Example 1.4 are equivalent in the sense that they generate the same topologies. Moreover, compactness is equivalent to closedness and boundedness in each of those metrics.

Example 1.5. Let $C([a,b],\mathbb{R}^n)$ denote the space of all continuous functions $f:[a,b]\to\mathbb{R}^n$.

1. $C([a,b],\mathbb{R}^n)$ is a vector space over $\mathbb{R}$.
2. If $\|f\| = \max\limits_{a\le t\le b} |f(t)|$, where $|\cdot|$ is a norm on $\mathbb{R}^n$, then $(C([a,b],\mathbb{R}^n), \|\cdot\|)$ is a Banach space.
3. Let M and K be two positive constants and define

$$L = \{f \in C([a,b],\mathbb{R}^n) : \|f\| \le M; |f(u) - f(v)| \le K|u-v|\}.$$

Then L is compact.

Proof (of part 3). Let $\{f_n\}$ be any sequence in L. The functions are uniformly bounded by M and have the same Lipschitz constant, K. So the sequence is uniformly equicontinuous. By the Ascoli–Arzelà theorem there is a subsequence $\{f_{n_k}\}$ that converges uniformly to a continuous function $f:[a,b]\to\mathbb{R}^n$. We now show that $f\in L$. Well, $|f_n(t)|\le M$ for each $t\in[a,b]$, so $|f(t)|\le M$ for each $t\in[a,b]$ and hence $\|f\|\le M$. Now fix $u,v\in[a,b]$ and $\varepsilon>0$. Since $\{f_{n_k}\}$ converges uniformly to f, there is $N\in\mathbb{N}$ such that $|f_{n_k}(t)-f(t)|<\varepsilon/2$ for all $t\in[a,b]$ and $k\ge N$. So fixing any $k\ge N$, we have

$$\begin{aligned}|f(u)-f(v)| &= |f(u)-f_{n_k}(u)+f_{n_k}(u)-f_{n_k}(v)+f_{n_k}(v)-f(v)|\\ &\le |f(u)-f_{n_k}(u)|+|f_{n_k}(u)-f_{n_k}(v)|+|f_{n_k}(v)-f(v)|\\ &< \varepsilon/2+K|u-v|+\varepsilon/2 = K|u-v|+\varepsilon.\end{aligned}$$

Since $\varepsilon>0$ was arbitrary, $|f(u)-f(v)|\le K|u-v|$. Hence $f\in L$. We have demonstrated that $\{f_n\}$ has a subsequence converging to an element of L. Hence L is compact. □

Example 1.6. Consider $\mathbb{R}$ as a vector space over $\mathbb{R}$ and define the metric $d(x,y) = \dfrac{|x-y|}{1+|x-y|}$. For each $x\in\mathbb{R}$, we define $\|x\| = d(x,0)$. Explain why $\|\cdot\|$ is not a norm on $\mathbb{R}$.

Example 1.7. Let $\phi:[a,b]\to\mathbb{R}^n$ be continuous, and let S be the set of continuous functions $f:[a,c]\to\mathbb{R}^n$ with $c>b$ and $f(t)=\phi(t)$ for $a\le t\le b$. Define $\rho(f,g) = \|f-g\| = \sup\limits_{a\le t\le c<} |f(t)-g(t)|$ for $f,g\in S$. Then (S,ρ) is a complete metric space but not a Banach space since $f+g$ is not in S.

Copyright Elsevier 2022

Example 1.8. Let (S, ρ) be the space of continuous bounded functions $f : (-\infty, 0] \to \mathbb{R}$ with $\rho(f, g) = \|f - g\| = \sup_{-\infty < t \leq 0} |f(t) - g(t)|$. Then:

1. (S, ρ) is a Banach space.
2. The set $L = \{f \in S : \|f\| \leq 1, |f(u)f(v)| \leq |u - v|\}$ is not compact in (S, ρ).

Proof (of 2). Consider the sequence of functions defined

$$f_n(t) = \begin{cases} 0 & \text{if } t \leq -n, \\ \frac{t}{n} + 1 & \text{if } -n < t \leq 0. \end{cases}$$

Then the sequence converges pointwise to $f = 1$, but $\rho(f_n, f) = 1$ for all $n \in \mathbb{N}$. So there is no subsequence of $\{f_n\}$ converging in the norm $\|\cdot\|$ (i.e., converging uniformly) to f. ☐

Example 1.9. Let (S, ρ) be the space of continuous functions $f : (-\infty, 0] \to \mathbb{R}^n$ with

$$\rho(f, g) = \sum_{n=1}^{\infty} 2^{-n} \rho_n(f, g)/\{1 + \rho_n(f, g)\},$$

where

$$\rho_n(f, g) = \max_{-n \leq s \leq 0} |f(s) - g(s)|,$$

and $|\cdot|$ is the Euclidean norm on $\mathbb{R}^n$. Then:

1. (S, ρ) is a complete metric space. The distance between all functions is bounded by 1.
2. $(S, +, \cdot)$ is a vector space over $\mathbb{R}$.
3. (S, ρ) is not a Banach space because ρ does not define a norm, since $\rho(x, 0) = \|x\|$ does not satisfy $\|\alpha x\| = |\alpha|\|x\|$.
4. Let M and K be given positive constants. Then the set

$$L = \{f \in S : \|f\| \leq M \text{ on } (-\infty, 0], |f(u) - f(v)| \leq K|u - v|\}$$

is compact in (S, ρ).

Proof (of 4). Let $\{f_n\}$ be a sequence in L. It is clear that if $f_n \to f$ uniformly on compact subsets of $(-\infty, 0]$, then we have $\rho(f_n, f) \to 0$ as $n \to \infty$. Let us begin by considering $\{f_n\}$ on $[-1, 0]$. Then the sequence is uniformly bounded and equicontinuous, and so there is a subsequence, say $\{f_n^1\}$, converging uniformly to some continuous f on $[-1, 0]$. Moreover, the argument of Example 1.5 shows that $|f(t)| \leq M$ and $|f(u) - f(v)| \leq K|u - v|$. Next, we consider $\{f_n^1\}$ on $[-2, 0]$. Then the sequence is uniformly bounded and equicontinuous, and so there is a subsequence, say $\{f_n^2\}$, converging uniformly, say, to some continuous f on $[-2, 0]$.

Copyright Elsevier 2022

Continuing this way, we arrive at $F_n = f_n^n$, which has a subsequence of $\{f_n\}$ converging uniformly on compact subsets of $(-\infty, 0]$ to a function $f \in L$. This proves that L is compact. □

We leave the proof of next result to the reader.

Theorem 1.4.2. *Let $g : (-\infty, 0] \to [1, \infty)$ be a continuous strictly decreasing function with $g(0) = 1$ and $g(r) \to \infty$ as $r \to -\infty$. Let $(S, |\cdot|_g)$ be the space of continuous functions $f : (-\infty, 0] \to \mathbb{R}^n$ for which*

$$|f|_g := \sup_{-\infty < t \le 0} \frac{|f(t)|}{|g(t)|}$$

exists. Then:

1. *$(S, |\cdot|_g)$ is a Banach space.*
2. *Let M and K be given positive constants. Then the set*

$$L = \{f \in S : \|f\| \le M \text{ on } (-\infty, 0], |f(u) - f(v)| \le K|u - v|\}$$

is compact in (S, ρ).

Definition 1.4.10. Let (E, ρ) be a metric space, and let $D : E \to E$. The operator or mapping D is a contraction if there exists $\alpha \in (0, 1)$ such that

$$\rho\Big(D(x), D(y)\Big) \le \alpha\rho(x, y).$$

The next theorem is known by the name of Caccioppoli theorem, or the Banach contraction mapping principle [9]. A proof can be found in many places, such as Burton [15] or Smart [58].

Theorem 1.4.3. *(Contraction mapping principle) Let (E, ρ) be a complete metric space, and let $D : E \to E$ be a contraction operator. Then there exists a unique $\phi \in E$ such that $D(\phi) = \phi$. Moreover, if $\psi \in E$ and if $\{\psi_n\}$ is defined inductively by $\psi_1 = D(\psi)$ and $\psi_{n+1} = D(\psi_n)$, then $\psi_n \to \phi$, the unique fixed point.*

Proof. Let $y_0 \in E$ and define the sequence $\{y_n\}$ in E by $y_1 = Dy_0$, $y_2 = Dy_1 = D(Dy_0) = D^2 y_0, \ldots, y_n = Dy_{n-1} = D^n y_0$. Next, we show that $\{y_n\}$ is a Cauchy sequence. Indeed, if $m > n$, then

$$\begin{aligned}
\rho(y_n, y_m) &= \rho(D^n y_0, D^m y_0) \\
&\le \alpha\rho(D^{n-1} y_0, D^{m-1} y_0) \\
&\vdots \\
&\le \alpha^n \rho(y_0, y_{m-1})
\end{aligned}$$

Copyright Elsevier 2022

$$
\begin{aligned}
&\le \alpha^n \big\{\rho(y_0, y_1) + \rho(y_1, y_2) + \ldots + \rho(y_{m-n-1}, y_{m-n})\big\} \\
&\le \alpha^n \big\{\rho(y_0, y_1) + \alpha\rho(y_0, y_1) + \ldots + \alpha^{m-n-1}\rho(y_0, y_1)\big\} \\
&\le \alpha^n \rho(y_0, y_1)\big\{1 + \alpha + \ldots + \alpha^{m-n-1}\big\} \\
&\le \alpha^n \rho(y_0, y_1)\frac{1}{1-\alpha}.
\end{aligned}
$$

Thus, since $\alpha \in (0, 1)$, we have that

$$\rho(y_n, y_m) \to 0 \text{ as } n \to \infty.$$

This shows that the sequence $\{y_n\}$ is Cauchy. Since (E, ρ) is a complete metric space, $\{y_n\}$ has a limit, say y in E. Since the mapping D is continuous, we have that

$$D(y) = D(\lim_{n\to\infty} y_n) = \lim_{n\to\infty} D(y_n) = \lim_{n\to\infty} y_{n+1} = y,$$

and y is a fixed point. It remains to show that y is unique. Let $x, y \in E$ be such that $D(x) = x$ and $D(y) = y$. Then

$$0 \le \rho(x, y) = \rho\big(D(x), D(y)\big) \le \alpha\rho(x, y),$$

which implies that

$$0 \le (1-\alpha)\rho(x, y) \le 0.$$

Since $1 - \alpha \neq 0$, we must have $\rho(x, y) = 0$, and hence $x = y$. This completes the proof. □

Another form of the contraction mapping principle:

Theorem 1.4.4. *(Contraction mapping principle, Banach fixed point theorem) Let (E, ρ) be a complete metric space, and let $P : E \to E$ be such that P^m is a contraction for some fixed positive integer m. Then there is a unique $x \in E$ such that $P(x) = x$.*

1.5 Variation of parameters

In this section we develop the variation of parameters formula, which we use, in one form or another, throughout this book. Consider the nonhomogeneous differential equation

$$x'(t) = a(t)x(t) + g(t, x(t)),\ x(t_0) = x_0,\ t \ge t_0 \ge 0, \tag{1.5.1}$$

where $g \in C([0, \infty) \times \mathbb{R}, \mathbb{R})$ and $a \in C([0, \infty), \mathbb{R})$.

Copyright Elsevier 2022

Multiplying both sides of (1.5.1) by the integrating factor $e^{-\int_{t_0}^t a(u)du}$ and observing that

$$\frac{d}{dt}\Big(x(t)e^{-\int_{t_0}^t a(u)du}\Big) = x'(t)e^{-\int_{t_0}^t a(u)du} - a(t)x(t)e^{-\int_{t_0}^t a(u)du},$$

we arrive at

$$\frac{d}{dt}\Big(x(t)e^{-\int_{t_0}^t a(u)du}\Big) = g(t, x(t))e^{-\int_{t_0}^t a(u)du}.$$

Integration of the above expression from t_0 to t and using $x(t_0) = x_0$ yield

$$x(t)e^{-\int_{t_0}^t a(u)du} = x_0 + \int_{t_0}^t g(s, x(s))e^{-\int_{t_0}^s a(u)du} ds,$$

from which we get

$$x(t) = x_0 e^{\int_{t_0}^t a(u)du} + \int_{t_0}^t g(s, x(s))e^{\int_s^t a(u)du} ds,\ t \ge t_0 \ge 0. \tag{1.5.2}$$

It can be easily shown that if $x(t)$ satisfies (1.5.2), then it satisfies (1.5.1). Expression (1.5.2) is known as the variation of parameters formula. Note that (1.5.2) is a functional equation in x since the integrand is a function of x. If we replace the function g with a function $h \in C([0, \infty), \mathbb{R})$, then (1.5.2) takes the special form

$$x(t) = x_0 e^{\int_{t_0}^t a(u)du} + \int_{t_0}^t h(s)e^{\int_s^t a(u)du} ds,\ t \ge t_0 \ge 0. \tag{1.5.3}$$

Another special form of (1.5.2) is that if the function $a(t)$ is constant for all $t \ge t_0$ and g is replaced with h as before, then from (1.5.3), we have that

$$x(t) = x_0 e^{a(t-t_0)} + \int_{t_0}^t e^{a(t-s)} h(s) ds,\ t \ge t_0 \ge 0. \tag{1.5.4}$$

It is easy to compute, using (1.5.4), that the differential equation

$$x'(t) = 2x(t) + t,\ x(0) = 3,$$

has the solution

$$x(t) = \frac{13}{4}e^{2t} - \frac{t}{2} - \frac{1}{4}.$$

Remark 1.6. The variation of parameters formula given by (1.5.2) is valid for

$$g \in C(\mathbb{R} \times \mathbb{R}, \mathbb{R}) \quad \text{and} \quad a \in C(\mathbb{R}, \mathbb{R}).$$

Next, we consider the following application regarding the variation of parameters.

Copyright Elsevier 2022

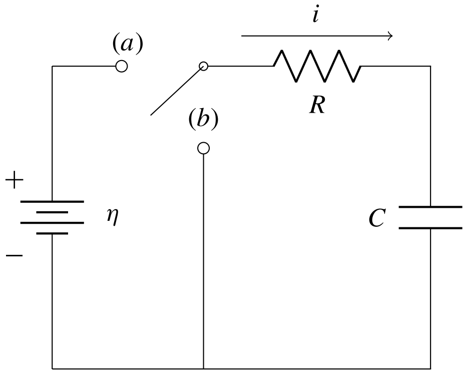

FIGURE 1.2

RC circuit.

1.5.1 RC circuit

Fig. 1.2 shows a resistor R and capacitor C connected in a series. The battery connected to this circuit by a switch provides an electromotive force, or emf force η. Initially, there is no charge on the capacitor. When the switch is flipped to (a), the battery connects, and the capacitor charges. Similarly, when the switch is flipped to (b), the battery disconnects, and the capacitor discharges with energy dissipated in the resistor. Our aim is to determine the voltage drop across the capacitor during charging and discharging.

We start by observing that the voltage drops across a capacitor V_C and resistor V_R are given by

$$V_C = \frac{q}{C}, \quad V_R = iR,$$

respectively, where C is the capacitance and R is the resistance. The current i and the charge q are related by the relation

$$i = \frac{dq}{dt}.$$

From the first equation, we have

$$\frac{dV_C}{dt} = \frac{dq}{dt}.\frac{1}{C} = \frac{i}{C} = \frac{1}{C}\frac{V_R}{R},$$

which implies that

$$V_R = RC\frac{dV_C}{dt}.$$

Copyright Elsevier 2022

Kirchhoff’s voltage law states that the *emf* η in any closed loop is equal to the sum of the voltage drops in that loop. When the switch is thrown to (a), this gives

$$V_R + V_C = \eta.$$

Substituting V_R into $V_R + V_C = \eta$ gives the linear differential equation

$$\frac{dV_C}{dt} + V_C\frac{1}{RC} = \eta\frac{1}{RC}, \quad V_C(0) = 0.$$

An application of the variation of parameters formula gives the solution

$$V_C(t) = e^{-t/RC}\int_0^t \frac{\eta}{RC}e^{s/RC}\,ds,$$

or

$$V_C(t) = \eta\left(1 - e^{-t/RC}\right).$$

Thus the voltage starts at zero and rises slowly but exponentially to η with characteristic time scale given by RC. In other words,

$$V_C(t) \to \eta \text{ as } t \to \infty.$$

Now suppose the switch is thrown to (b). Then by Kirchhoff’s voltage law

$$V_R + V_C = 0,$$

which results in the differential equation

$$\frac{dV_C}{dt} + V_C\frac{1}{RC} = 0, \quad V_C(0) = 0.$$

Then the solution during the discharge phase is given by

$$V_C(t) = \eta e^{-t/RC},$$

and the voltage decays exponentially to zero with the characteristic time scale given by RC.

1.6 Special differential equations

Next, we consider second-order nonlinear differential equations of the form

$$x'' = f(t, x, x'), \tag{1.6.1}$$

where $f(t, x, y)$ is a function of three variables defined in the region $D = \{(t, x, y) : a_1 < t < a_2, b_1 < x < b_2, c_1 < y < c_2\}$ with f, $\frac{\partial f}{x}$, and $\frac{\partial f}{\partial y}$ continuous in D. Little is

Copyright Elsevier 2022

known about how to solve (1.6.1) except in certain particular cases. Two interesting and useful cases occur when (1.6.1) has one of the following forms:

$$F(t, x', x'') = 0 \tag{1.6.2}$$

or

$$F(x, x', x'') = 0. \tag{1.6.3}$$

For (1.6.2), the transformation $x' = u$ transforms the original second-order differential equation into a first-order differential equation $F(t, u, u') = 0$, which can be solved. To see this, we consider the nonlinear second-order differential equation

$$tx'' + 2x' + t = 1, \; t > 0.$$

For $x' = u$, we have the first-order differential equation $tu' + 2u + t = 1$. Using the variation of parameters formula given by (1.5.2), we arrive at

$$u = \frac{c_1}{t^2} + \frac{1}{2} - \frac{t}{3}$$

for some constant c_1. Since $x(t) = \int u(t)dt$, we arrive at the general solution

$$x(t) = -\frac{c_1}{t} + \frac{t}{2} - \frac{t^2}{6} + c_2$$

for some constant c_2.

Equations of the form (1.6.3) can be reduced to first-order equations by the substitution $x' = u$. Eq. (1.6.3) is now replaced by the equivalent system of two differential equations

$$x' = u, \quad F(x, u, u') = 0.$$

By using x as the independent variable we have

$$x'' = \frac{du}{dt} = \frac{du}{dx}\frac{dx}{dt} = \frac{du}{dx}u.$$

Hence (1.6.3) reduces to the first-order differential equation

$$F(x, u, u\frac{du}{dx}) = 0.$$

As an application, we consider the differential equation

$$x'' + (x')^2 x + x'x = 0, \;\; x(0) = 0, \; x'(0) = -1.$$

Then, under the mentioned substitution, we have the new first-order differential equation

$$u\frac{du}{dx} + u^2 x + ux = 0$$

Copyright Elsevier 2022

or

$$\frac{du}{dx} + xu = -x.$$

By the variation of parameters, we arrive at the solution

$$u = -1 + ce^{\frac{x^2}{2}}.$$

Using $u = -1$ when $x = 0$, we have $c = 0$. Now using the transformation $x' = u$, it follows that

$$\frac{dx}{dt} = -1.$$

Using $x(0) = 0$, we arrive at the solution

$$x(t) = -t.$$

1.7 Exercises

Exercise 1.1. Show that the differential equation

$$x'(t) = \frac{3}{2}x^{1/3}(t),\ x(0) = 0,\ t \in \mathbb{R}$$

has infinitely many solutions.

Exercise 1.2. Show that the differential equation

$$x'(t) = x^{\alpha}(t),\ x(0) = 0,\ t \in \mathbb{R}$$

has infinitely many solutions for $\alpha \in (0, 1)$.

Exercise 1.3. Find the escape time of the solutions for the differential equation

$$x'(t) = x^2(t),\ x(t_0) = x_0 \neq 0,\ t \in \mathbb{R}.$$

Exercise 1.4. Show that the solution $x(t, t_0, x_0)$ of

$$x'(t) = t,\ x(t_0) = x_0 \neq 0,\ t \geq 0$$

is stable but unbounded.

Exercise 1.5. Let $x = (x_1, x_2, \ldots, x_n)$, $x_i \in \mathbb{R}$, $i = 1, 2, \ldots, n$.

Show that $\|x\| = \sum_{i=1}^{n} x_i^2$ does not define a norm.

Copyright Elsevier 2022

Exercise 1.6. Consider the following power series $L(x)$, which is also known as Euler's dilogarithm function:

$$L(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2}.$$

(a) Compute the domain of convergence for $L(x)$. Be sure to give a full analysis of the endpoints.
(b) Show that $L(x)$ uniformly converges on its entire domain of convergence. (Use Weierstrass M-test.)
(c) Explain why the $L(x)$ is continuous on its domain of convergence.

Exercise 1.7. Consider the sequence $\{f_n\}$ of functions $f_n : \mathbb{R} \to \mathbb{R}$ defined by

$$f_n(x) = \frac{nx}{\sqrt{1+n^2x^2}}.$$

Find the pointwise limit of this sequence as $n \to \infty$. Does the sequence converge uniformly on $\mathbb{R}$?

Exercise 1.8. Show that the space $C(I, \mathbb{R})$, where I is any compact subset of $\mathbb{R}$, endowed with the supremum norm

$$||f||_\infty = \sup_{t \in I} |f(t)|$$

is a Banach space.

Exercise 1.9. Show that the space Ω_T of all continuous T-periodic functions given by

$$\Omega_T = \{f \in C(\mathbb{R}, \mathbb{R}) : f(t+T) = f(T) \text{ for all } t \in \mathbb{R}\}$$

with the maximum norm

$$||f|| = \max_{t \in [0,T]} |f(t)|$$

is a Banach space.

Exercise 1.10. Show that the space $C([0, 1], \mathbb{R})$ endowed with the L^1 norm

$$||f||_1 = \int_0^1 |f(t)| dt$$

is a metric space but is not complete.

Exercise 1.11. For $1 \le p < \infty$, let

$$l_p = \{a = (a_1, a_2, \ldots) : a_k \in \mathbb{R}, \sum_k |a_k|^p < \infty\}$$

Copyright Elsevier 2022

and

$$||a||_p = \Big(\sum_k |a_k|^p\Big)^{1/p}.$$

Show that l_p endowed with $||\cdot||_p$ is a Banach space.

Exercise 1.12. Prove Remark 1.1.

Exercise 1.13. Find a continuous solution satisfying

$$x'(t) + x(t) = f(t),\ x(0) = 0,$$

where $f(t) = \begin{cases} 1, & 0 \le t \le 1, \\ 0, & t > 1. \end{cases}$

Is the solution differentiable at $t = 1$?

Exercise 1.14. Find a continuous solution satisfying

$$x'(t) + 2tx(t) = f(t),\ x(0) = 2,$$

where $f(t) = \begin{cases} t, & 0 \le t < 1, \\ 0, & t \ge 1. \end{cases}$

Is the solution differentiable at $t = 1$?

Exercise 1.15. For the SI epidemic model of Section 1.3, use Eq. (1.3.1) and the relation $I + S = 1$ to obtain a first-order differential equation in terms of S and S'. Assume a positive condition $S(0) = 1 - I(0) := S_0$ and find the solution $S(t)$ and $\lim\limits_{t\to\infty} S(t)$.

Exercise 1.16. Let $d > 0$, and let $f : [0, d] \to \mathbb{R}$ be continuous. Let k be any constant and suppose $x(t)$ solves the differential inequality

$$x'(t) \le kx(t) + f(t),\ t \in [0, d].$$

Show that

$$x(t) \le x(0)e^{kt} + \int_0^t e^{k(t-s)} f(s)ds,\ t \in [0, d].$$

Hint: There is a continuous and nonnegative function $g(t)$ such that

$$x'(t) + g(t) = kx(t) + f(t),\ t \in [0, d].$$

Exercise 1.17. Suppose a function $f : [0, d] \times \mathbb{R} \to \mathbb{R}$ is continuous and that $f(t, x)$ is bounded for all $(t, x) \in [0, d] \times \mathbb{R}$, where d is a positive constant. Suppose $x = \varphi(t)$ solves the differential equation

$$x'(t) = xf(t, x),\ x(0) = 1,\ t \in [0, d].$$

Show that there is a constant K such that $\varphi(t) \le e^{Kt}$ for all $t \in [0, d]$.

Copyright Elsevier 2022

Exercise 1.18. In Problems 1–5 solve the differential equation. If no initial conditions are given, find the general solution.

1. $t^2x'' + t = 1$, $t > 0$.
2. $t^2x'' + 2tx' = 1$, $t > 0$.
3. $xx'' - 2(x')^2 + 4x^2 = 0$, $x(1) = 1$, $x'(1) = 2$.
4. $\sin(x')x'' = \sin(x)$, $x(1) = 2$, $x'(1) = 1$.
5. $tx'' - x' = t^2e^t$, $t > 0$.

Copyright Elsevier 2022

CHAPTER

Existence and uniqueness

2

In Chapter 1 we laid out the basics we need to use in this and the following chapters. This chapter is devoted to the existence and uniqueness and the continuation of solutions. We limit our discussions and proofs to scalar differential equations, and in Chapter 3 we indicate how the theory can be naturally extended to vector equations.

2.1 Existence and uniqueness of solutions

This section is devoted to the existence and uniqueness of solutions of the initial value problem (IVP)

$$x' = f(t,x), \quad x(t_0) = x_0, \tag{2.1.1}$$

where we assume that $f : D \to \mathbb{R}$ is continuous and D is a subset of $\mathbb{R} \times \mathbb{R}$. In the case the differential equation (2.1.1) is linear, a solution can be found. However, in general, this approach is not feasible when the differential equation is not linear, and hence another approach must be indirectly adopted that establishes the existence of a solution of (2.1.1). For the development of the existence theory, we need a broader definition of Lipschitz condition.

Definition 2.1.1. The function $f : D \to \mathbb{R}$ is said to satisfy the *global* Lipschitz condition in x if there exists a Lipschitz constant $k > 0$ such that

$$|f(t,x) - f(t,y)| \le k|x-y| \text{ for } (t,x),\ (t,y) \in D. \tag{2.1.2}$$

Definition 2.1.2. The function $f : D \to \mathbb{R}$ is said to satisfy a *local* Lipschitz condition in x if for any $(t_1, x_1) \in D$, there exists a domain $D_1 \subset D$ such that $f(t,x)$ satisfies a Lipschitz condition in x on D_1, that is, there exists a positive constant k_1 such that

$$|f(t,x) - f(t,y)| \le K_1|x-y|, \text{ for } (t,x),\ (t,y) \in D_1. \tag{2.1.3}$$

Definition 2.1.1 can be easily extended to functions $f : D \to \mathbb{R}^n$, where $D \subset \mathbb{R} \times \mathbb{R}^n$ under a proper norm. Let $R = \{(t,x) : |t| \le a,\ |x| \le b\}$ be any rectangle in D. If f and $\frac{\partial f}{\partial x}$ are continuous on R, which is the case in this chapter, then f and $\frac{\partial f}{\partial x}$ are bounded on R. Therefore there exist positive constants $\mathscr{M}$ and $\mathscr{K}$ such that

$$|f(t,x)| \le \mathscr{M} \text{ and } |\frac{\partial f}{\partial x}| \le \mathscr{K} \tag{2.1.4}$$

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00008-5
Copyright © 2023 Elsevier Inc. All rights reserved.

Copyright Elsevier 2022

for all points (t, x) in R. Now for any two points (t, x_1), (t, x_2) in R, by the mean value theorem there exists a constant $\eta \in (x_1, x_2)$ such that

$$f(t, x_1) - f(t, x_2) = \frac{\partial f}{\partial x}(t, \eta)(x_1 - x_2),$$

from which it follows that

$$\begin{aligned} |f(t, x_1) - f(t, x_2 &\le |\frac{\partial f}{\partial x}(t, \eta)||x_1 - x_2| \\ &\le \mathscr{K}|x_1 - x_2|. \end{aligned} \tag{2.1.5}$$

We have shown that if f and $\frac{\partial f}{\partial y}$ are continuous on R, then f satisfies a global Lipschitz condition on R.

Example 2.1. Consider $f(t, x) = x^{2/3}$ in the rectangle $R = \{(t, x) : |t| \le 1,\ |x| \le 1\}$. We claim f does not satisfy the Lipschitz condition on R. Consider the pair of points (t, x_1) and $(t, 0)$ in R where $x_1 > 0$. Then

$$\frac{|f(t, x_1) - f(t, 0)}{x_1 - 0}| = x_1^{-1/3} \to \infty \text{ as } x_1 \to 0^+,$$

and hence there exists no $\mathscr{K}$ such that (2.1.5) holds.

Remark 2.1. Consider (2.1.1) on the rectangle $D \subset \mathbb{R} \times \mathbb{R}$ defined by

$$D = \{(t, x) : |t - t_0| \le a,\ |x - x_0| \le b\},$$

where a and b are positive constants. Let

$$\tau = t - t_0,\ u = x - x_0, \text{ and } g(\tau, u) = f(\tau + t_0, u + x_0).$$

Then the function g is defined on the rectangle

$$D^* = \{(\tau, u) : -a \le \tau \le a,\ -b \le u \le b\},$$

and the IVP (2.1.1) is equivalent to the IVP problem

$$u' = g(\tau, u),\ u(0) = 0.$$

For emphasis, we restate the following definition.

Definition 2.1.3. We say that x is a solution of (2.1.1) on an interval I if $x : I \to \mathbb{R}$ is differentiable, $(t, x(t)) \in D$ for $t \in I$, $x'(t) = f(t, x(t))$ for $t \in I$, and $x(t_0) = x_0$ for $(t_0, x_0) \in D$.

In preparation for the next theorem, we observe that the IVP (2.1.1) is equivalent to

$$x(t) = x_0 + \int_{t_0}^{t} f(s, x(s))ds. \tag{2.1.6}$$

Copyright Elsevier 2022

Relation (2.1.6) is an *integral equation* since it contains an integral of the unknown function x. This integral is not a formula for the solution, but rather it provides another relation satisfied by a solution of (2.1.1). We have the following definition.

Definition 2.1.4. We say $x : I \to \mathbb{R}$ is a solution of the integral equation (2.1.6) on an interval I if $t_0 \in I$, x is continuous on I, $(t, x(t)) \in D$ for $t \in I$, and (2.1.6) is satisfied for $t \in I$.

The next theorem is fundamental for the proof of the existence theorems.

Theorem 2.1.1. *Let D be an open subset of $\mathbb{R}^2$, and let $(t_0, x_0) \in D$. Then x is a solution of (2.1.1) on an interval I if and only if x satisfies the integral equation given by (2.1.6) on I.*

Proof. Let $x(t)$ be a solution of (2.1.1) on an interval I. Then $t_0 \in I$, x is differentiable on I, and hence x is continuous on I. Moreover, $(t, x(t)) \in D$ for $t \in I$, $x(t_0) = x_0$, and $x'(t) = f(t, x(t))$ for $t \in I$. Now an integration of $x'(t) = f(t, x(t))$ from t_0 to t gives (2.1.6) for $t \in I$. For the converse, if x satisfies (2.1.6) for $t \in I$, then $t_0 \in I$, and x is continuous on I. Moreover, $(t, x(t)) \in D$ for $t \in I$, and (2.1.6) is satisfied for $t \in I$. Thus $x(t)$ is differentiable on I. By differentiating (2.1.6) with respect to t, we arrive at $x'(t) = f(t, x(t))$ for all $t \in I$ and $x(t_0) = x_0 + \int_{t_0}^{t_0} f(s, x(s))ds = x_0$. This completes the proof. $\square$

A graduate textbook in differential equations would be incomplete without the statement and proof of Picard's local existence and uniqueness using successive approximations. In the next section we prove similar theorems on Banach spaces using fixed point theory.

We note that Picard's local existence and uniqueness theorem and Cauchy–Peano existence theorem are widely used, and variant proofs of the theorems can be found in [17], [29], [31], [54], and [70].

The heart of proving our next results is the construction of a sequence of functions that converge to a limit function that satisfies the IVP (2.1.1), although the members of the sequence individually do not.

Theorem 2.1.2 addresses the three basic issues:
(1) Members of the constructed sequence $\{x_n\}$ exist for all time.
(2) The sequence converges, and the limiting function satisfies the integral equation (2.1.6) and hence the IVP (2.1.1).
(3) The limiting function, which is a solution of (2.1.1), is unique.

Theorem 2.1.2. *(Picard's local existence and uniqueness) Let $D \subset \mathbb{R} \times \mathbb{R}$ be defined as*

$$D = \{(t, x) : |t - t_0| \le a,\ |x - x_0| \le b\},$$

where a and b are positive constants. Assume that $f \in C(D, \mathbb{R})$ and f satisfies the Lipschitz condition (2.1.2). Let

$$M = \max_{(t,x)\in D} |f(t, x)| \tag{2.1.7}$$

Copyright Elsevier 2022

and

$$h = \min\{a, \frac{b}{M}\}. \tag{2.1.8}$$

Then the IVP (2.1.1) has a unique solution, denoted by $x(t, t_0, x_0)$, on the interval $|t - t_0| \leq h$ and passing through (t_0, x_0). Furthermore,

$$|x(t) - x_0| \leq b \textit{ for } |t - t_0| \leq h.$$

Proof. Before we begin the proof, we recommend to look at Fig. 2.1.

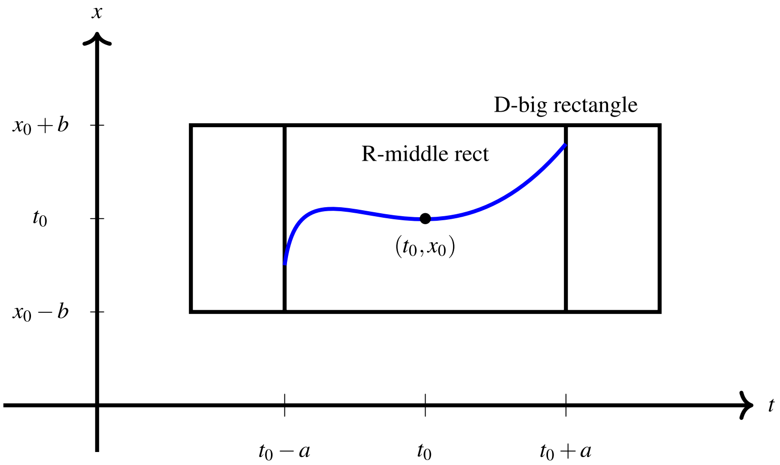

FIGURE 2.1

Interval of existence.

First, we note that since f is continuous on D, condition (2.1.7) is automatically implied. The idea of the proof is to construct a sequence of functions $\{x_n\}$ that converges uniformly to a unique x on the interval $|t - t_0| \leq h$ and is a solution of (2.1.1). We begin by successively defining a sequence of functions $\{x_n\}$ for $|t - t_0| \leq h$ by setting

$$\begin{aligned} x_0(t) &= x_0, \\ x_1(t) &= x_0 + \int_{t_0}^{t} f(s, x_0(s))ds, \\ &\vdots \\ x_n(t) &= x_0 + \int_{t_0}^{t} f(s, x_{n-1}(s))ds. \end{aligned} \tag{2.1.9}$$

According to (2.1.7) and (2.1.8), we have that

$$|x_1(t) - x_0| \leq hM \leq b \text{ for } |t - t_0| \leq h.$$

Copyright Elsevier 2022

Therefore $\int_{t_0}^{t} f(s, x_1(s))ds$ can be defined for $|t - t_0| \leq h$, and hence

$$|x_2(t) - x_0| \leq hM \leq b.$$

Similarly, we may show that $x_3(t), \ldots, x_n(t)$ are well defined on $|t - t_0| \leq h$. Thus

$$|x_n(t) - x_0| = |\int_{t_0}^{t} f(s, x_{n-1}(s))ds| \leq M|t - t_0|. \tag{2.1.10}$$

Next, we show that $\{x_n\}$ converges uniformly to a function, say x, on $|t - t_0| \leq h$. Note that

$$x_n(t) = x_0(t) + [x_1(t) - x_0(t)] + [x_2(t) - x_1(t)] + \cdots + [x_n(t) - x_{n-1}(t)],$$

or

$$x_n(t) = x_0(t) + \sum_{j=0}^{n-1} [x_{j+1}(t) - x_j(t)].$$

Taking the limit if it exists, we have

$$\lim_{n\to\infty} x_n(t) = x_0(t) + \lim_{n\to\infty} \sum_{j=0}^{n-1} [x_{j+1}(t) - x_j(t)]. \tag{2.1.11}$$

Our next task is to compute $|x_{j+1}(t) - x_j(t)|$. Using (2.1.9) and then (2.1.2) followed by (2.1.10) give

$$\begin{aligned}
|x_2(t) - x_1(t)| &\leq \int_{t_0}^{t} \big|f(s, x_1(s)) - f(s, x_0(s))\big| ds \\
&\leq K \int_{t_0}^{t} \big|x_1(s) - x_0(s)\big| ds \\
&\leq KM \int_{t_0}^{t} |s - t_0| ds = KM \int_{t_0}^{t} (s - t_0) ds \\
&= KM \frac{(t - t_0)^2}{2}, \ |t - t_0| \leq a.
\end{aligned}$$

In a similar fashion, we obtain

$$\begin{aligned}
|x_3(t) - x_2(t)| &\leq \int_{t_0}^{t} \big|f(s, x_2(s)) - f(s, x_1(s))\big| ds \\
&\leq K \int_{t_0}^{t} \big|x_2(s) - x_1(s)\big| ds
\end{aligned}$$

Copyright Elsevier 2022

$$\begin{aligned}&\leq K\int_{t_0}^{t} KM\frac{(s-t_0)^2}{2}ds\\&= MK^2\frac{(t-t_0)^3}{3!},\ |t-t_0|\leq a.\end{aligned}$$

Continuing this way, we arrive at

$$|x_j(t)-x_{j-1}(t)|\leq MK^{j-1}\frac{(t-t_0)^j}{j!}. \tag{2.1.12}$$

To complete the induction argument, we assume that (2.1.12) holds for j and show that it holds for $j+1$. Using (2.1.12), we arrive at

$$\begin{aligned}|x_{j+1}(t)-x_j(t)| &\leq \int_{t_0}^{t}\big|f(s,x_j(s))-f(s,x_{j-1}(s))\big|ds\\&\leq K\int_{t_0}^{t}\big|x_j(s)-x_{j-1}(s)\big|ds\\&\leq K\int_{t_0}^{t}MK^{j-1}\frac{(s-t_0)^j}{j!}ds\\&= MK^j\frac{(t-t_0)^{j+1}}{j!(j+1)} = MK^j\frac{(t-t_0)^{j+1}}{(j+1)!},\ |t-t_0|\leq a.\end{aligned}$$

Next, we substitute (2.1.12) into (2.1.11) and get

$$\begin{aligned}\lim_{n\to\infty}x_n(t) &= x_0+\frac{M}{K}\lim_{n\to\infty}\sum_{j=0}^{n-1}\frac{|K(t-t_0)|^{j+1}}{(j+1)!}\\&\leq x_0+\frac{M}{K}\lim_{n\to\infty}\sum_{j=0}^{n-1}\frac{(Kh)^{j+1}}{(j+1)!}\\&\leq x_0+\frac{M}{K}\Big(e^{Kh}-1\Big)<\infty.\end{aligned}$$

Hence, by the Weierstrass M-test, $\{x_n(t)\}$ converges uniformly, say to a function $x(t)$. Next, we show that $x(t)$ is a solution of (2.1.1) on D. We have

$$\begin{aligned}|x(t)-x_0| &= |x(t)-x_n(t)+x_n(t)-x_0|\\&\leq |x(t)-x_n(t)|+|x_n(t)-x_0|\\&\leq |x(t)-x_n(t)|+M|t-t_0|\end{aligned}$$

for every fixed $t\in(t_0-h,t_0+h)$. As a result,

$$|x(t)-x_0| = \lim_{x\to\infty}|x(t)-x_n(t)|+M|t-t_0|$$

Copyright Elsevier 2022

$$
\begin{aligned}
&= 0 + M|t - t_0| \\
&\leq Mh \leq b
\end{aligned}
$$

for $t \in (t_0 - h, t_0 + h)$. So $x(t) \in D$. If the sequence $\{x_n(t)\}$ converges uniformly and $\{x_n(t)\}$ is continuous on the interval $|t - t_0| \leq h$, then

$$\lim_{n\to\infty} \int_{t_0}^{t} f(s, x_n(s))ds = \int_{t_0}^{t} \lim_{n\to\infty} f(s, x_n(s))ds$$

by the uniform continuity of f. As a consequence,

$$
\begin{aligned}
x(t) &= \lim_{n\to\infty} x_{n+1}(t) \\
&= x_0 + \lim_{n\to\infty} \int_{t_0}^{t} f(s, x_n(s))ds \\
&= x_0 + \int_{t_0}^{t} \lim_{n\to\infty} f(s, x_n(s))ds \\
&= x_0 + \int_{t_0}^{t} f(s, \lim_{n\to\infty} x_n(s))ds \\
&= x_0 + \int_{t_0}^{t} f(s, x(s))ds,
\end{aligned}
$$

that is,

$$x(t) = x_0 + \int_{t_0}^{t} f(s, x(s))ds, \ \ |t - t_0| \leq h. \tag{2.1.13}$$

The integrand $f(s, x(s))$ in (2.1.13) is a continuous function, and hence $x(t)$ is differentiable with respect to t, and its derivative is equal to $f(t, x(t))$. So the proof of the existence is complete. It remains to show that the solution $x(t)$ on D is unique. Let $y(t)$ be another solution of (2.1.1) with $y(t_0) = x_0$. Then

$$y(t) = x_0 + \int_{t_0}^{t} f(s, y(s))ds.$$

Let

$$N = \sup_{|t - t_0| \leq h} |x(t) - y(t)|.$$

Then by the Lipschitz condition, we have

$$|x(t) - y(t)| \leq K \int_{t_0}^{t} \big|x(s) - y(s)\big|ds \tag{2.1.14}$$

or

$$|x(t) - y(t)| \leq KN|t - t_0|.$$

Copyright Elsevier 2022

The substitution of this estimate into (2.1.14) yields

$$|x(t) - y(t)| \leq KN|t - t_0|^2/(2!) \text{ for } |t - t_0| \leq h.$$

Repeating this substitution, we obtain

$$|x(t) - y(t)| \leq KN\frac{|t - t_0|^m}{m!}, m = 1, 2, \ldots,$$

for $|t - t_0| \leq h$. Since the right side of this inequality tends to zero as $m \to \infty$, we have that

$$N = \sup_{|t-t_0|\leq h} |x(t) - y(t)| = 0.$$

This completes the proof. ☐

We will give another proof of the uniqueness once Gronwall's inequality is introduced. To illustrate the above procedure, we provide the following examples.

Example 2.2. We consider the IVP

$$x'(t) = 2t(1 + x), \; x(0) = 0.$$

Set $x_0(t) = 0$. Then for any $n \geq 1$, we have the recurrent formula

$$x_n(t) = \int_0^t 2s(1 + x_{n-1}(s))ds.$$

For $n = 1$, we have

$$x_1(t) = \int_0^t 2sds = t^2,$$

and for $n = 2$,

$$x_2(t) = \int_0^t 2s(1 + s^2)ds = t^2 + \frac{t^4}{2}.$$

We leave it to the reader to verify that

$$x_n(t) = t^2 + \frac{t^4}{2} + \frac{t^6}{3!} + \ldots, \frac{t^{2n}}{n!} = \sum_{i=0}^{n} \frac{(t^2)^i}{i!} - 1.$$

Definition 2.1.5. A sequence $\{x_n\}$ of functions in $C([a, b], \mathbb{R})$ converges uniformly to $x \in C([a, b], \mathbb{R})$ if $\lim_{n\to\infty} ||x_n - x|| = 0$.

It was established in Example 2.2 that

$$x_n(t) = \sum_{i=0}^{n} \frac{(t^2)^i}{i!} - 1$$

Copyright Elsevier 2022

and the true solution of the IVP is given by $x(t) = e^{t^2} - 1$ on the interval [0, 1]. Thus

$$\lim_{n\to\infty} ||x_n - x|| = \lim_{n\to\infty} \Big[\max_{t\in[0,1]} \Big| \sum_{i=0}^{n} \frac{(t^2)^i}{i!} - 1 - (e^{t^2} - 1) \Big| \Big] = \lim_{n\to\infty} \sum_{i=n+1}^{\infty} \frac{1}{i!} = 0.$$

Therefore

$$\lim_{n\to\infty} x_n(t) = \lim_{n\to\infty} \sum_{i=0}^{n} \frac{(t^2)^i}{i!} - 1 = e^{t^2} - 1.$$

Example 2.3. Next, we use Theorem 2.1.2 to find the interval of existence of the unique solution of

$$x'(t) = 1 + x^2,\ x(0) = 1.$$

Let

$$D = \{(t, x) : |t| \le a,\ |x - 1| \le b\},$$

where a and b are constants. It is clear that

$$M = \max_{(t,x)\in D} |f(t, x)| = 1 + (1 + b)^2$$

and

$$h = \min\{a, \frac{b}{M}\} = \min\{a, \frac{b}{1 + (1 + b)^2}\}.$$

So we must find the maximum of the function $g(b) = \dfrac{b}{1 + (1 + b)^2}$. Using calculus, we see that the function g has its maximum at $b = \sqrt{2}$ and is given by $g(\sqrt{2}) = \frac{\sqrt{2}}{1+(1+\sqrt{2})^2}$. Thus the interval of existence and uniqueness is

$$|t| \le \frac{\sqrt{2}}{1 + (1 + \sqrt{2})^2}, \quad \text{or } t \in \Big[-\frac{\sqrt{2}}{1 + (1 + \sqrt{2})^2}, \frac{\sqrt{2}}{1 + (1 + \sqrt{2})^2}\Big].$$

Now suppose in Example 2.3 we chose $D = \{(t, x) : |t| \le 10,\ |x - 1| \le b\}$, that is, $a = 10$. Then the interval of existence found above is much smaller or included in $(-10, 10)$. Recall that the interval of existence is included in D.

The next corollary is an immediate consequence of Theorem 2.1.2 and the discussion leading to (2.1.5).

Corollary 2.1. *Suppose $D \subset \mathbb{R} \times \mathbb{R}$, $f \in C(D, \mathbb{R})$, and $\frac{\partial f}{\partial x}$ is continuous on D. Then for any $(t_0, x_0) \in D$, the IVP (2.1.1) has a unique solution on an interval containing t_0 in its domain.*

As an example, consider

$$x'(t) = t x^{1/2}.$$

Copyright Elsevier 2022

Then

$$f(t,x) = tx^{1/2} \text{ and } \frac{\partial f}{\partial x} = \frac{t}{2x^{1/2}}$$

are continuous in the upper half-plane defined by $x > 0$. We conclude from Corollary 2.1 that for any point $(t_0, x_0),\ x_0 > 0$, there is some interval around t_0 on which the given differential equation has a unique solution.

Unlike Theorem 2.1.2, the next Cauchy–Peano theorem only guarantees the existence of a solution and not uniqueness. This is due to the fact that f is not required to be Lipschitz.

Based on Remark 2.1, we may restate Theorem 2.1.2.

Theorem 2.1.3. *If f and $\frac{\partial f}{\partial x}$ are continuous on the rectangle*

$$D^* = \{(t,x) : -a \le t \le a,\ -b \le x \le b\},$$

where a and b are positive constants, then there is a number h in the interval $(0, a]$ such that the IVP

$$x' = f(t,x),\ \ x(0) = 0,$$

has a unique solution, denoted by $x(t,0,0)$, on the interval $-h \le t \le h$. Furthermore,

$$|x(t)| \le b \textit{ for } |t| \le h.$$

Example 2.4. As an application, we consider the IVP

$$x' = t(x+1)^2,\ \ x(0) = 0,$$

on the rectangle

$$D^* = \{(t,x) : -1 \le t \le 1,\ -2 \le x \le 2\}.$$

It readily follows that the IVP has the solution $x(t) = \dfrac{t^2}{2-t^2}$. We want this solution to be in D^*. This means that $|t| \le 1$ and $\dfrac{t^2}{2-t^2} \le 2$. This is true if and only if $-\dfrac{2}{\sqrt{3}} \le t \le \dfrac{2}{\sqrt{3}}$, from which it follows that $h = \dfrac{2}{\sqrt{3}}$. If we choose a larger b, then we can arrive at a larger h. However, h must be chosen so that $h < \sqrt{2}$. This is due to the fact that

$$\lim_{t \to (\sqrt{2})^-} \frac{t^2}{2-t^2} = \infty.$$

Theorem 2.1.4. *(Cauchy–Peano existence theorem) Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be continuous in a neighborhood of a point $(t_0, x_0) \in \mathbb{R}^2$. Then there exists $\alpha > 0$ such that the*

Copyright Elsevier 2022

IVP (2.1.1) has a solution ϕ on the interval $I := [t_0 - \alpha, t_0 + \alpha]$, that is, there exists a function (not necessarily unique) $\phi = \phi(t)$ defined on I such that

$$\phi'(t) = f(t, \phi(t)),\ t \in I,$$

and $\phi(t_0) = x_0$.

Proof. Since f is continuous in a neighborhood of the point $(t_0, x_0) \in \mathbb{R}^2$, there exists a positive constant a such that the rectangle

$$D = \{(t, x) : |t - t_0| \le a,\ |x - x_0| \le a\}$$

is centered at (t_0, x_0). Moreover, $M = \max_{(t,x)\in D} |f(t, x)|$ exists. Next, we set $\alpha := \dfrac{a}{M}$. By Theorem 2.1.1, we know that $\phi = \phi(t)$ satisfies the IVP (2.1.1) if and only if

$$\phi(t) = x_0 + \int_{t_0}^{t} f(s, \phi(s))ds. \tag{2.1.15}$$

Since f is uniformly continuous on the compact set D, given $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon)$ such that

$$|t - \tilde{t}| < \delta \text{ and } |x - \tilde{x}| < \delta \text{ imply } |f(t, x) - f(\tilde{t}, \tilde{x})| < \varepsilon$$

for all $(t, x), (\tilde{t}, \tilde{x}) \in D$. Therefore let $\varepsilon = \varepsilon_n = \dfrac{1}{n}$ and $\delta = \delta_n$, $n = 1, 2, \ldots$. Choose points $t_j^{(n)}$ with $t_0^{(n)} = t_0$ and $t_{k(n)} = t_0 + \alpha$ for $0 \le j \le k(n)$ with $|t_{j+1}^{(n)} - t_j^{(n)}| \le \dfrac{\delta_n}{M}$. We define the approximation ϕ_n on $[x_0, x_0 + \alpha]$ by $\phi_n(t_0) = x_0$ and $\phi_n'(t) = f(t_0, x_0)$, $t_0 \le t \le t_1^{(n)}$. Then it is clear that $x_1^{(n)} = \phi_n(t_1^{(n)})$. Continuing in this manner, we get that

$$\phi_n'(t) = f(t_j^{(n)}, x_j^{(n)}) \text{ for } t_j^{(n)} \le t \le t_{j+1}^{(n)}. \tag{2.1.16}$$

Note that ϕ_n is piecewise continuous and may have a jump discontinuity in its derivative at the partition points, and hence we define

$$\triangle_n(t) = \begin{cases} \phi_n'(t) - f(t, \phi_n(t)), & t_j^{(n)} < t < t_{j+1}^{(n)}, \\ 0, & t = x_j^{(n)}. \end{cases}$$

As a consequence, we may define

$$\phi_n(t) = x_0 + \int_{t_0}^{t} \phi_n'(s)ds = x_0 + \int_{t_0}^{t} [f(s, \phi_n(s)) + \triangle_n(s)]ds.$$

Next, we try to have an upper bound on $\triangle_n(t)$. Note that from (2.1.16) and the definition of $\triangle_n(t)$ we have that for $t_j^{(n)} < t < t_{j+1}^{(n)}$,

Copyright Elsevier 2022

$$\begin{aligned}|\triangle_n(t)| &= \left|f(t_j^{(n)}, x_j^{(n)}) - f(t, \phi_n(t))\right|, \; t_j^{(n)} < t < t_{j+1}^{(n)} \\ &\leq |x_j^{(n)} - \phi_n(t)| \leq |x_j^{(n)} - x_{j+1}^{(n)}| \\ &\leq M|t_j^{(n)} - t_{j+1}^{(n)}| \\ &\leq M\frac{\delta_n}{M} = \delta_n = \varepsilon_n = \frac{1}{n},\end{aligned}$$

where we have used that

$$|s - t_j^{(n)}| \leq |x_{j+1}^{(n)} - x_j^{(n)}| \leq \delta_n.$$

By the Ascoli–Arzelà theorem, there exists a uniformly convergent subsequence of ϕ_n that converges to

$$\phi(t) = \lim_{k\to\infty} \phi_{n_k}(t) \; \text{ for } \; t \in [t_0 - \alpha, t_0 + \alpha],$$

that is,

$$\phi_{n_k}(t) = x_0 + \int_{t_0}^{t} [f(s, \phi_{n_k}(s)) + \triangle_n(s)]ds,$$

which converges to

$$\phi(t) = x_0 + \int_{t_0}^{t} [f(s, \phi(s))ds.$$

This completes the proof. □

Example 2.5. Consider the IVP

$$x'(t) = 2tx^{2/3}, \; x(0) = 0.$$

Then $f(t,x) = 2tx^{2/3}$ is continuous everywhere, whereas $\dfrac{\partial f(t,x)}{\partial x} = \dfrac{4t}{3x^{1/3}}$ is not continuous at the points where $x = 0$. Here $x_0 = 0$, and no matter how small we chose $b > 0$, the interval $[-b, b]$ will always contain 0. Therefore we cannot apply Theorem 2.1.2. Instead, we will use Theorem 2.1.4. Let $a = 1$. Then on the rectangle

$$D = \{(t,x) : |t| \leq 1, \; |x| \leq 1\},$$

we have

$$M = \max_{(t,x)\in D} |f(t,x)| = 2 \; \text{ and } \; \alpha = \frac{1}{2} = 0.5.$$

Therefore by Peano's existence theorem, we have at least one solution $x : [-0.5, 0.5] \to [-1, 1]$. As a matter of fact, the IVP has the two solutions $x(t) = 0$ and $x(t) = \frac{t^6}{27}$, both going through the initial point $(0,0)$.

Copyright Elsevier 2022

Next, we state and prove Gronwall's inequality, which plays an important role throughout this book in proving the boundedness, stability, and uniqueness.

Theorem 2.1.5. *(Gronwall's inequality) Let C be a nonnegative constant, and let u, v be nonnegative continuous functions on $[a, b]$ such that*

$$v(t) \leq C + \int_a^t v(s)u(s)ds, \ a \leq t \leq b. \tag{2.1.17}$$

Then

$$v(t) \leq Ce^{\int_a^t u(s)ds}, \ a \leq t \leq b. \tag{2.1.18}$$

In particular, if $C = 0$, then $v = 0$.

Proof. Let $C > 0$, and let $h(t) = C + \int_a^t v(s)u(s)ds$. Then

$$h'(t) = v(t)u(t) \leq h(t)u(t).$$

So we have the differential inequality

$$h'(t) - h(t)u(t) \leq 0.$$

Multiplying both sides of the above expression by the integrating factor $e^{-\int_a^t u(s)ds}$, we get

$$\left(h(t)e^{-\int_a^t u(s)ds}\right)' \leq 0.$$

Integrating both sides from a to t gives

$$h(t)e^{-\int_a^t u(s)ds} - h(a) \leq 0, \ \text{ or } \ h(t) \leq e^{\int_a^t u(s)ds}.$$

Finally,

$$v(t) \leq h(t) \leq Ce^{\int_a^t u(s)ds}.$$

If $C = 0$, then from (2.1.17) it follows that

$$v(t) \leq \int_a^t v(s)u(s)ds \leq \frac{1}{m} + \int_a^t v(s)u(s)ds, \ a \leq t \leq b$$

for any $m \geq 1$. Then from what we have just proved we arrive at

$$v(t) \leq \frac{1}{m}e^{\int_a^t u(s)ds}, \ a \leq t \leq b.$$

Thus for any fixed $t \in [a, b]$, we can let $m \to \infty$ to conclude that $v(t) \leq 0$, and it follows that $v(t) = 0$ for all $t \in [a, b]$. This completes the proof. ☐

Copyright Elsevier 2022

Now we are in a position to revisit the proof of the uniqueness of the solution in Theorem 2.1.2 by using Gronwall's inequality.

Just for a reminder, we assume that the hypotheses of Theorem 2.1.2 hold. Suppose (2.1.1) has two solutions $x(t)$ and $y(t)$ and set $w(t) = x(t) - y(t)$. Then $w'(t) = x'(t) - y'(t)$. Therefore

$$\int_{t_0}^{t} w'(s)ds = w(t) - w(t_0) = \int_{t_0}^{t} \Big(f(s, x(s)) - f(s, y(s))\Big)ds \text{ with}$$

$$w(t_0) = x(t_0) - y(t_0) = 0.$$

So we arrive at

$$\begin{aligned}|w(t)| &\le \int_{t_0}^{t} |f(s, x(s)) - f(s, y(s))|ds \\ &\le K \int_{t_0}^{t} |x(s) - y(s)|ds \\ &= K \int_{t_0}^{t} |w(s)|ds.\end{aligned}$$

Applying Gronwall's inequality with $v(t) = |w(t)|$, $C = 0$, and $u(s) = 1$, we get $|w(t)| = 0$ for all t such that $|t - t_0| \le h$. We conclude that $w(t) = 0$ and hence $x(t) = y(t)$.

The next theorem shows the significance of Theorem 2.1.5.

Theorem 2.1.6. *Suppose* $\phi(t)$ *is continuous on* $[0, \infty)$ *and differentiable on* $(0, \infty)$. *If*

$$\lim_{t\to\infty} \phi(t) = 0$$

and

$$\int_{0}^{\infty} |\phi'|dt < \infty,$$

then all solutions of

$$x'' + (1 + \phi(t))x = 0 \tag{2.1.19}$$

are bounded.

Proof. Multiply both sides of (2.1.19) by x' and integrate the resulting equation from 0 to t to arrive at

$$\frac{(x'(t))^2}{2} + \frac{(x(t))^2}{2} + \int_{0}^{t} \phi(s)x(s)x'(s)ds = c_1,$$

Copyright Elsevier 2022

where c_1 is a constant. Integrating by parts the third term from the left and rearranging give

$$
\begin{aligned}
x^2(t)\big(1+\phi(t)\big) &= 2c_2 - (x'(t))^2 + \int_0^t \phi'(s)x^2(s)ds \\
&\le 2c_2 + \int_0^t \phi'(s)x^2(s)ds,
\end{aligned}
$$

where c_2 is a constant. Since $\lim_{t\to\infty}\phi(t) = 0$, we may choose t_0 large enough so that $1+\phi(t) \ge \frac{1}{2}$ for all $t \ge t_0$. This translates into

$$
x^2(t)(\frac{1}{2}) \le x^2(t)\big(1+\phi(t)\big) \le 2c_2 + \int_0^t \phi'(s)x^2(s)ds
$$

or

$$
x^2(t) \le 4c_2 + 2\int_0^t |\phi'(s)|x^2(s)ds,\ t \ge t_0.
$$

Thus by Theorem 2.1.5 we have that

$$
\begin{aligned}
x^2(t) &\le 4c_2 e^{2\int_0^t |\phi'(s)|ds} \\
&\le 4c_2 e^{2\int_0^\infty |\phi'(s)|ds} = M < \infty \text{ for some positive constant } M
\end{aligned}
$$

and for all $t \ge 0$. Since $x(t)$ is continuous on $0 \le t \le t_0$ and t_0 is arbitrary, it follows that $x(t)$ is bounded. ☐

2.2 Existence on Banach spaces

In this brief section we discuss the existence of solutions of the IVP (2.1.1) on Banach spaces using the contraction mapping principle. For reminder, we restate the IVP

$$
x' = f(t,x),\ \ x(t_0) = x_0, \tag{2.2.1}
$$

where we assume that $f : D \to \mathbb{R}$ is continuous and D is an open subset of $\mathbb{R}\times\mathbb{R}$. The next theorem is another version of Picard's theorem where f satisfies global Lipschitz condition.

Theorem 2.2.1. *(Picard theorem; global version) Let $f \in C(\mathbb{R}\times\mathbb{R},\mathbb{R})$, and let f satisfy the global Lipschitz condition (2.1.2), that is, there exists a constant $K > 0$ such that*

$$
|f(t,x) - f(t,y)| \le K|x-y| \text{ for all } (t,x),(t,y) \in D.
$$

Let $h = \dfrac{1}{2K}$ and $t_0 \in (-h,h)$. Then there exists a unique $x : (-h,h) \to \mathbb{R}$ satisfying the IVP (2.2.1).

Copyright Elsevier 2022

Proof. Define the space

$$\mathbb{B} = C([-h, h], \mathbb{R}).$$

Then $\mathbb{B}$ endowed with the norm

$$||x|| = \max_{t \in [-h,h]} |x(t)|$$

is a Banach space. By Theorem 2.1.1, we have that

$$x(t) = x_0 + \int_{t_0}^{t} f(s, x(s))ds, \quad t \geq t_0. \tag{2.2.2}$$

The problem comes down to finding a fixed point of the operator $\mathscr{P} : \mathbb{B} \to \mathbb{B}$ defined by

$$\mathscr{P}(x)(t) = x_0 + \int_{t_0}^{t} f(s, x(s))ds.$$

By a fixed point we mean that there is an element $x \in \mathbb{B}$ such that $\mathscr{P}(x) = x$, which is equivalent to finding a solution of (2.2.2) and therefore of (2.2.1). Note that $\mathscr{P}$ assigns to any function $x \in \mathbb{B}$ another function, which we denote by $\mathscr{P}x$. Thus for $\mathscr{P}x$ to be defined, we need to evaluate its value at some $t \in [-h, h]$. It is clear that $\mathscr{P}$ is continuous in x. To show that $\mathscr{P}(x)(t)$ is a contraction, we let $x, y \in \mathbb{B}$. Then for $t \in [-h, h]$, we have that

$$\begin{aligned}
\left|\mathscr{P}(x)(t) - \mathscr{P}(y)(t)\right| &\leq \int_{t_0}^{t} |f(s, x(s)) - f(s, y(s))|ds \\
&\leq K \int_{t_0}^{t} |x(s) - y(s)|ds \\
&\leq hK\|x - y\| \\
&\leq \frac{1}{2}\|x - y\|.
\end{aligned}$$

Thus

$$\begin{aligned}
\|\mathscr{P}(x) - \mathscr{P}(y)\| &\leq \sup_{t \in [-h,h]} \left|\mathscr{P}(x)(t) - \mathscr{P}(y)(t)\right| \\
&\leq K \int_{t_0}^{t} |x(s) - y(s)|ds \\
&\leq \frac{1}{2}\|x - y\|.
\end{aligned}$$

Thus $\mathscr{P}$ defines a contraction mapping on the Banach space $\mathbb{B}$, and hence it has a unique $x \in \mathbb{B}$ that is a solution of (2.2.1) by Theorem 2.1.1. This completes the proof. □

Copyright Elsevier 2022

Theorem 2.2.2. *(Picard Theorem; local version) Let* $\mathscr{D} \subset \mathbb{R} \times \mathbb{R}$ *be an open set containing* $(0, x_0)$*, and let* $f \in C(\mathscr{D}, \mathbb{R})$ *be such that* $|f| \le M$ *for a positive constant* M*. Suppose* f *satisfies the local Lipschitz condition in* x *on* $\mathscr{D}$ *with Lipschitz constant* $K > 0$*. Choose*

$$h \in (0, \frac{1}{2K}) \ \text{ so that } [-h, h] \times \{|x - x_0| \le hM\} \subset \mathscr{D}$$

(note that such a choice of h is possible since the set $\mathscr{D}$ *is open). Then there exists a unique* $x : (-h, h) \to \mathbb{R}$ *satisfying the IVP* (2.2.1).

Proof. Let $I = [-h, h]$, where h is as chosen in the hypothesis. Let $\mathbb{B} = \{x \in \mathbb{R} : |y - x_0| \le hM\}$. Define $\mathscr{P} : C(I, \mathbb{B}) \to C(I, \mathbb{B})$ by

$$\mathscr{P}(x)(t) = x_0 + \int_{t_0}^{t} f(s, x(s))ds.$$

The problem reduces to showing that $\mathscr{P}(x) = x$. First, we show that $\mathscr{P}$ is well-defined. It is clear from the choice of h that if $x \in C(I, \mathbb{B})$, then $f(t, x)$ is well-defined for all $t \in [-h, h]$, and hence $x_0 + \int_{t_0}^{t} f(s, x(s))ds$ is well-defined. Moreover, since $|f| \le M$, we have that $x_0 + \int_{t_0}^{t} f(s, x(s))ds$ is continuous. Thus $\mathscr{P}(x)(t)$ is a continuous map. Finally,

$$|\mathscr{P}(x)(t) - x_0| \le \int_{t_0}^{t} |f(s, x(s))|ds \le hM.$$

Thus $\mathscr{P}(x)(t) \in \mathbb{B}$ for all $t \in [-h, h]$, and hence $\mathscr{P}(x) \in C(I, \mathbb{B})$ assigns to any function $x \in \mathbb{B}$ another function, which we denote by $\mathscr{P}x$. Thus for $\mathscr{P}x$ to be defined, we need to evaluate its value at some $t \in [-h, h]$. It is clear that $\mathscr{P}$ is continuous in x. To show that $\mathscr{P}(x)(t)$ is a contraction, we let $x, y \in C(I, \mathbb{B})$. Then for each $t \in [-h, h]$, we have that

$$\begin{aligned}
\|\mathscr{P}(x) - \mathscr{P}(y)\| &\le \sup_{t\in[-h,h]} \left|\mathscr{P}(x)(t) - \mathscr{P}(y)(t)\right| \\
&\le K \int_{t_0}^{t} |x(s) - y(s)|ds \\
&\le Kt \max_{|s|\le t} |x(s) - y(s)| \\
&\le Kh\|x - y\| = \frac{1}{2}\|x - y\|.
\end{aligned}$$

Thus $\mathscr{P}$ defines a contraction mapping on the Banach space $C(I, \mathbb{B})$, and hence it has a unique $x : (-h, h) \to \mathbb{R}$ that is a solution of (2.2.1) by Theorem 2.1.1. This completes the proof. □

Consider the differential equation $x'(t) = 1 + x^2$. Theorem 2.2.1 cannot be applied here since $f(t, x) = 1 + x^2$ does not satisfy the global Lipschitz condition on $\mathbb{R}$,

Copyright Elsevier 2022

whereas Theorem 2.2.2 is applicable. Moreover, Theorem 2.2.2 only requires finding $\mathscr{D} \in \mathbb{R} \times \mathbb{R}$ containing $(0, x_0)$. In addition, in both Theorems 2.2.1 and 2.2.2 the initial time t_0 can be chosen so that $t_0 \neq 0$.

2.3 Existence theorem for linear equations

In this section we eloquently apply Theorem 1.4.4 to show that the linear nonhomogeneous differential equation

$$x'(t) = a(t)x(t) + f(t), \tag{2.3.1}$$

where $a, f \in C(\mathbb{R}, \mathbb{R})$, has a unique solution $\phi \in C(\mathbb{R}, \mathbb{R})$ with $\phi(t_0) = x_0$. We have the following theorem.

Theorem 2.3.1. *Let* $(t_0, x_0) \in \mathbb{R}^2$, *and let* $a, f \in C(\mathbb{R}, \mathbb{R})$. *Then* (2.3.1) *has a unique solution* $\phi : (-\infty, \infty) \to \mathbb{R}$ *with* $\phi(t_0) = x_0$.

Proof. Let $s, M > 0$. Find M such that for a given s, we have $|a(t)| \leq M$ for $t \in [t_0 - s, t_0 + s]$. Let $\mathbb{B} = C\big([t_0 - s, t_0 + s], \mathbb{R}\big)$. Then the space $\mathbb{B}$ endowed with the supremum norm $\| \cdot \|$ is a Banach space. Theorem 2.1.1 implies that

$$x(t) = x_0 + \int_{t_0}^{t} a(u)x(u)du + \int_{t_0}^{t} f(u)du.$$

For $x \in \mathbb{B}$, define $\mathscr{P} : \mathbb{B} \to \mathbb{B}$ by

$$\mathscr{P}(x)(t) = x_0 + \int_{t_0}^{t} a(u)x(u)du + \int_{t_0}^{t} f(u)ds.$$

Clearly, $\mathscr{P}(x)(t)$ is a continuous map. Let $x, y \in \mathbb{B}$. Then

$$\begin{aligned}\|\mathscr{P}(x) - \mathscr{P}(y)\| &\leq \sup_{t \in [t_0 - s,\, t_0 + s]} \big|\mathscr{P}(x)(t) - \mathscr{P}(y)(t)\big| \\ &\leq M \int_{t_0}^{t} |x(u) - y(u)| du \\ &\leq Ms\|x - y\|\end{aligned}$$

or

$$\|\mathscr{P}(x) - \mathscr{P}(y)\| \leq Ms\|x - y\|.$$

Now if $Ms = \alpha < 1$, then $\mathscr{P}$ is a contraction, and by Theorem 1.4.3, there is a unique fixed point $\phi \in \mathbb{B}$, that is, $\mathscr{P}(\phi) = \phi$, which is a solution of (2.3.1) on $[t_0 - s, t_0 + s]$. However, we claimed that the solution exists and is unique on $(-\infty, \infty)$. To show

Copyright Elsevier 2022

this, we use Theorem 1.4.4 by letting s be an arbitrary and find an integer $m > 0$ such that $\mathscr{P}^m$ is a contraction:

$$\begin{aligned}|\mathscr{P}^2(x)(t) - \mathscr{P}^2(y)(t)| &= |\mathscr{P}(\mathscr{P}(x))(t) - \mathscr{P}(\mathscr{P}(y))(t)| \\ &\leq \sup_{t\in[t_0-s,\, t_0+s]} \Big| \int_{t_0}^{t} |a(u)||\mathscr{P}(x)(u) - \mathscr{P}(y)(u)|du\Big| \\ &\leq M^2||x-y||\Big|\int_{t_0}^{t} |u-t_0|du| \\ &\leq M^2||x-y||\,|t-t_0|^2/2!.\end{aligned}$$

Continuing this process, we claim that

$$|\mathscr{P}^m(x)(t) - \mathscr{P}^m(y)(t)| \leq M^m|t-t_0|^m||x-y||/m!$$

for positive integer m. The claim is already proved for $m = 1, 2$. We assume that it holds for a positive integer k and then show that the result holds for $k+1$. Indeed,

$$\begin{aligned}|\mathscr{P}^{k+1}(x)(t) - \mathscr{P}^{k+1}(y)(t)| &= |\mathscr{P}(\mathscr{P}^k(x))(t) - \mathscr{P}(\mathscr{P}^k(y))(t)| \\ &\leq \sup_{t\in[t_0-s,\, t_0+s]} \Big| \int_{t_0}^{t} |a(u)||\mathscr{P}^k(x)(u) - \mathscr{P}^k(y)(u)|du\Big| \\ &\leq M^{k+1}||x-y||\Big|\int_{t_0}^{t} |u-t_0|^k du/k!| \\ &\leq M^{k+1}||x-y||\,|t-t_0|^{k+1}/(k+1)!.\end{aligned}$$

Thus

$$|\mathscr{P}^m(x)(t) - \mathscr{P}^m(y)(t)| \leq M^m s^m||x-y||/m!,$$

and for large m, we have

$$\frac{(ms)^m}{m!} < 1,$$

and the proof is complete by Theorem 1.4.4. ☐

2.4 Continuation of solutions

As we mentioned before, the interval of existence and uniqueness guaranteed by Theorem 2.1.1 is, in most cases, shorter than the actual interval of existence and uniqueness. This is misleading, since usually it is not the *maximal interval* of

Copyright Elsevier 2022

existence. To see this, we consider

$$x'(t) = tx,\ x(0) = 1.$$

Let

$$D = \{(t,x) : |t| \le a,\ |x-1| \le b\},$$

where a and b are constants. It is clear that

$$h = \min\{a, \frac{b}{M}\} = \min\{a, \frac{b}{a(1+b)}\}.$$

Thus for any positive constants a and b, we will always have $h < 1$, since either $h \le a$ or $h \le \frac{b}{a(1+b)} < 1/a$. On the other hand, the true solution of the IVP is $x(t) = e^{t^2/2}$, which exists for all $t \in \mathbb{R}$.

Consider the IVP

$$x' = f(t,x), \tag{2.4.1}$$

$$x(0) = x_0. \tag{2.4.2}$$

In the following theorems, we only consider $t \ge 0$ ($t \le 0$ is left as an exercise; see Exercise 2.17).

Theorem 2.4.1. *Suppose* $D = \mathbb{R} \times \mathbb{R}$, $f \in C(D, \mathbb{R})$, *and* $\frac{\partial f}{\partial x}$ *is continuous in* D. *If a solution* ξ *of* (2.4.1)–(2.4.2) *exists on* $[0, \alpha]$ *for some positive* α, *then it can be continued to a solution on some longer interval* $[0, \alpha + r]$ *for some positive constant* r.

Proof. Without loss of generality, we take $x_0 = 0$. Let

$$R = [\alpha - a, \alpha + a] \times [\xi(\alpha) - a, \xi(\alpha) + a],$$

where a is small enough so that $\alpha - a > 0$. Since f is continuous on the rectangle R containing the point $(\alpha, \xi(\alpha))$, we have, by applying Theorem 2.1.2 to the IVP

$$x' = f(t,x) \tag{2.4.3}$$

$$x(\alpha) = \xi(\alpha), \tag{2.4.4}$$

that a solution ϕ of (2.4.3)–(2.4.4) exists on some interval $[\alpha, \alpha + r]$. We claim that the function $\tilde{\xi}$ given by

$$\tilde{\xi}(t) = \begin{cases} \xi(t) & \text{if } 0 \le t \le \alpha, \\ \phi(t) & \text{if } \alpha < t \le \alpha + r, \end{cases}$$

solves (2.4.3)–(2.4.4) on $[0, \alpha + r]$. To do so, we must show that the left and right derivatives exist at α and are equal. Since $\phi(\alpha) = \xi(\alpha)$, the right derivative is given

Copyright Elsevier 2022

by

$$\begin{aligned}\lim_{s\to 0^+}\frac{\tilde{\xi}(\alpha+s)-\tilde{\xi}(\alpha)}{s} &= \lim_{s\to 0^+}\frac{\phi(\alpha+s)-\xi(\alpha)}{s}\\ &= \lim_{s\to 0^+}\frac{\phi(\alpha+s)-\phi(\alpha)}{s}\\ &= \phi'(\alpha)=f(\alpha,\phi(\alpha))\\ &= f(\alpha,\xi(\alpha))=\xi'(\alpha).\end{aligned}$$

Similarly, the left derivative is $\xi'(\alpha)$ due to the fact that ξ is a solution on $[0,\alpha]$. This completes the proof. □

Theorem 2.4.2. *The maximal interval of existence is open.*

Proof. Let J be the maximal interval of existence. If α of Theorem 2.4.1 is in J, then the same theorem shows that the interval $(\alpha-r,\alpha+r)$ is also in J. Hence J is open. This completes the proof. □

We have the following theorem.

Theorem 2.4.3. *Suppose* $D=\mathbb{R}\times\mathbb{R}$, $f\in C(D,\mathbb{R})$, *and* $\frac{\partial f}{\partial x}$ *is continuous in* D. *If* x *is a solution of* (2.4.1)–(2.4.2) *on some interval* J *containing* $t_0=0$, *then* x *is the unique solution on* J.

Proof. Suppose $J=(\alpha,w)$. Without loss of generality, let $x_0=0$. Then Theorem 2.2.1 implies that for some positive constant h, x is the unique solution on the closed interval $[-h,h]$. We will prove the uniqueness on the half-open interval $[0,w)$. Suppose there are two distinct solutions z_1 and z_2 of (2.4.1)–(2.4.2) on $[0,w)$. Then we have $z_1=z_2$ on $[0,h]$, and there exists $t^*\in(h,w)$ such that $z_1(t^*)\neq z_2(t^*)$. Let

$$\xi=\inf\{t\in(0,w): z_1(t^*)\neq z_2(t^*).$$

It follows that $h<\xi\le t^*$. We claim that $\xi<t^*$. Since $z_1(t^*)\neq z_2(t^*)$ and since z_1 and z_2 are continuous, $z_1\neq z_2$ on some interval to the left of t^*. This proves the claim. Due to the continuity of z_1 and z_2 and the equality $z_1=z_2$ on $[0,t^*]$, we must have $z_1(t^*)=z_2(t^*)$. In addition, we know from Theorem 2.4.1 that the IVP

$$x'=f(t,x),\ \ x(\xi)=z_1(\xi)$$

has a unique solution on some interval, say $[\xi-\beta,\xi+\beta]$, for some positive constant β. It follows that $z_1=z_2$ on $[\xi,\xi+\beta]$, which contradicts the definition of ξ. This shows that the solution x is unique on $[0,w)$. Similarly, we may prove the uniqueness on $(\alpha,0]$. This completes the proof. □

Theorem 2.4.4. *Assume the hypotheses of Theorems* 2.4.1 *and* 2.4.3. *If the maximal interval of existence* $J=[0,w)$, *where* $w<\infty$, *then the solution* $\phi(t)$ *of* $x'=f(t,x)$, $x(0)=0$, *is unbounded in* $[0,w)$.

Copyright Elsevier 2022

Proof. We prove by contradiction by assuming that the solution is bounded on $[0, w)$. Since $f(t, \phi)$ is bounded on $[0, w)$, there is a positive constant M such that $f(t, \phi)| \leq M$. Then by Theorem 2.1.1, we have that

$$\phi(t) = \int_{t_0}^{t} f(s, \phi(s))ds.$$

Let $\{t_j\} \uparrow w$. Then for any j and $k > j$, we have that

$$|\phi(t_k) - \phi(t_j)| = \left| \int_{t_j}^{t_k} f(s, \phi(s))ds \right| \leq M|t_j - t_k|.$$

Now the sequence $\{t_j\}$ is convergent and hence is a Cauchy sequence. Therefore $\{\phi(t_j\}$ must be a Cauchy sequence and so also convergent. Since the sequence $\{t_j\}$ was arbitrary and converging to w, we have that $\lim\limits_{t\to w^-} \phi(t)$ exists. Thus we may extend ϕ to w by letting $\phi(w)$ be the limit. Now consider the IVP

$$x' = f(t, x),$$
$$x(w) = \phi(w).$$

This IVP has a unique solution on $[w - r, w + r]$ for some positive constant r, which is an extension of the solution ϕ a little further. Thus $[0, w]$ is not the maximal positive interval of existence, which is a contradiction. This completes the proof. ☐

Consider the IVP

$$x'(t) = x^2, \;\; x(0) = 1.$$

The function $f(t, x) = x^2 \in C^1(\mathbb{R})$, and according to Theorem 2.1.2, the IVP has a unique solution on an open interval containing 0. Solving the IVP, we obtain the solution $x(t) = \frac{1}{t-1}$. The maximal interval of existence must include $t = 0$. Thus the solution is defined on its maximal interval of existence $(-\infty, 1)$. Furthermore,

$$\lim_{t\to 1^-} x(t) = -\infty.$$

According to Theorem 2.4.4, the IVP of Example 2.4 has the maximal interval of existence $(-\sqrt{2}, \sqrt{2})$. It is the case since

$$\lim_{t\to(\sqrt{2})^-} \frac{t^2}{2 - t^2} = \infty \quad \text{and} \quad \lim_{t\to(\sqrt{2})^+} \frac{t^2}{2 - t^2} = -\infty.$$

2.5 Dependence on initial conditions

One of the main characteristics a mathematical model should enjoy is that a solution should depend continuously on initial conditions. In other words, a small change in

Copyright Elsevier 2022

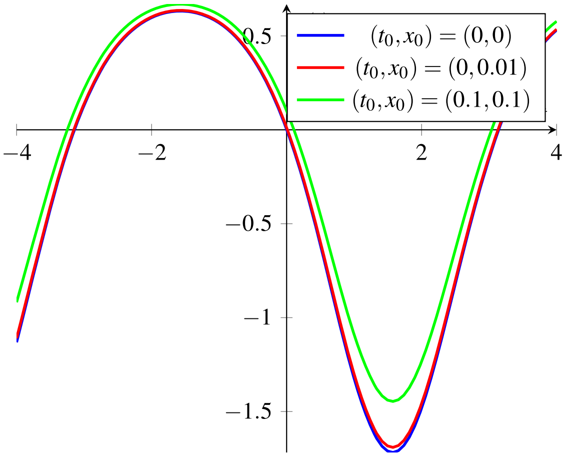

FIGURE 2.2

The three graphs stay close with three different initial conditions $(0, 0)$, $(0, 0.1)$, and $(0.1, 0.1)$.

the initial conditions should result in a small deviation in the solutions. We have seen that a solution $x(t)$ of the IVP

$$x' = f(t, x), \; x(t_0) = x_0 \tag{2.5.1}$$

depends not only on the time t, but also on the initial point (t_0, x_0). Thus, to emphasize such dependence, we use the notation $x(t, t_0, x_0)$ to denote $x(t)$. Consider

$$x'(t) = (x - 1)\cos(t), x(t_0) = x_0,$$

which has the solution

$$x(t) = \frac{e^{\sin(t)}}{e^{\sin(t_0)}}(x_0 - 1) + 1.$$

In Fig. 2.2 we plot the graphs of the solution for three different initial conditions, which shows the sensitivity of the solution to the initial data.

Example 2.6. The scalar (IVP)

$$x'(t) = x^2, \; x(0) = x_0, \;\; t \geq 0$$

has the solution

$$x(t) = \frac{x_0}{1 - x_0 t}$$

with maximal interval $[0, \frac{1}{x_0})$. As the initial value x_0 increases, the maximal interval of existence shrinks as depicted in Fig. 2.3.

Copyright Elsevier 2022

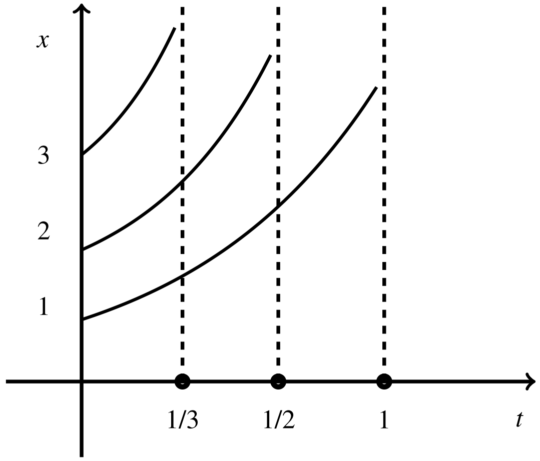

FIGURE 2.3

Dependence on x_0.

Example 2.7. In Fig. 2.4 we display the graph of

$$x' = x\sin(x) + t$$

and show its sensitivity to the initial data.

We have the following theorem.

Theorem 2.5.1. *Let $D \subset \mathbb{R} \times \mathbb{R}$, and suppose f and $\frac{\partial f}{\partial x}$ are continuous and bounded in D. Let x and y be two solutions of (2.5.1) passing through the initial conditions (t_0, x_0) and (t_0^*, x_0^*), respectively. Assume that the two solutions exist on a common interval (α, β), where α and β are finite. Then to each $\varepsilon > 0$, there corresponds $\delta > 0$ such that*

$$|t_0 - t_0^*| < \delta,\ |x_0 - x_0^*| < \delta \ \textit{imply}\ |x(t) - y(t)| < \varepsilon,\ t, t^* \in (\alpha, \beta).$$

Proof. Since f and $\frac{\partial f}{\partial x}$ are continuous and bounded on D, there are positive constants M and K such that

$$|f(t,x)| \le M,\ \ |\frac{\partial f}{\partial x}| \le K.$$

By Theorem 2.1.1, we have that for $t, t^* \in (\alpha, \beta)$,

$$x(t, t_0, x_0) = x_0 + \int_{t_0}^{t} f(s, x(s))ds,\ \ y(t^*, t_0^*, x_0^*) = x_0^* + \int_{t_0^*}^{t^*} f(s, y(s))ds.$$

Copyright Elsevier 2022

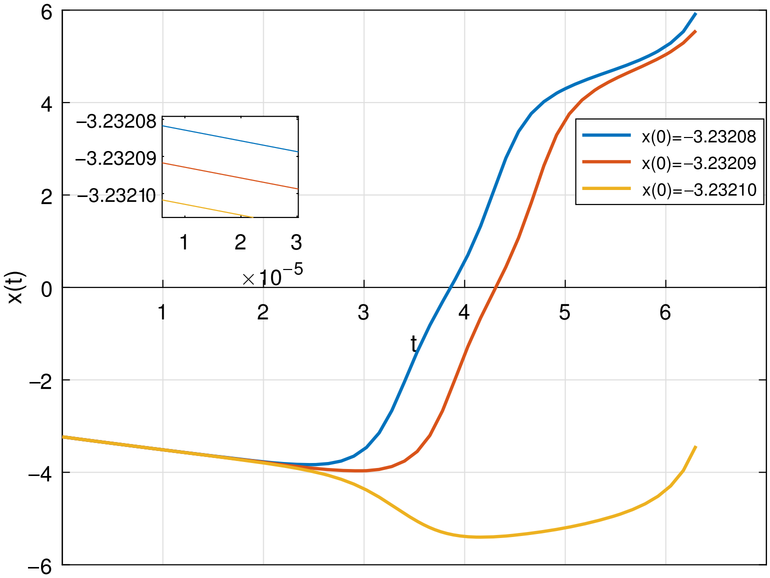

FIGURE 2.4

Sensitivity of solutions of $x' = x\sin(x) + t$ to the initial data.

By noticing that

$$\int_{t_0}^{t} f(s, x(s))ds = \int_{t_0^*}^{t} f(s, x(s))ds + \int_{t_0}^{t_0^*} f(s, x(s))ds,$$

$$\int_{t_0^*}^{t^*} f(s, y(s))ds = \int_{t_0^*}^{t} f(s, y(s))ds + \int_{t}^{t^*} f(s, y(s))ds,$$

we arrive at

$$\begin{aligned}
|x(t, t_0, x_0) - y(t^*, t_0^*, x_0^*)| &\leq |x_0 - x_0^*| + \left| \int_{t_0^*}^{t} |f(s, x(s)) - f(s, y(s))| ds \right| \\
&+ \left| \int_{t_0}^{t_0^*} |f(s, x(s))| ds \right| + \left| \int_{t}^{t^*} |f(s, y(s))| ds \right| \\
&\leq |x_0 - x_0^*| + K \left| \int_{t_0^*}^{t} |x(s)) - y(s)| ds \right| \\
&+ M|t_0^* - t_0| + M|t^* - t| \\
&\leq \delta + K \left| \int_{t_0^*}^{t} |x(s)) - y(s)| ds \right| + 2M\delta.
\end{aligned}$$

Copyright Elsevier 2022

Letting $v(t) = |x(t) - y(t)|$, $C = \delta + 2M\delta$, and $u(s) = K$, we obtain from Theorem 2.1.5 that

$$|x(t, t_0, x_0) - y(t^*, t_0^*, x_0^*)| \le \delta(1 + 2M)e^{K|t-t_0^*|} \le \delta(1 + 2M)e^{K(\alpha-\beta)}$$

or

$$|x(t, t_0, x_0) - y(t^*, t_0^*, x_0^*)| \le \varepsilon$$

for $\delta < \frac{\varepsilon e^{K(\alpha-\beta)}}{1+2M}$. This completes the proof. □

Theorem 2.5.1 shows that the solution $x(t, t_0, x_0)$ of (2.5.1) passing through the initial data (t_0, x_0) is a continuous function in (t, t_0, x_0). We end the chapter with the following theorem.

Theorem 2.5.2. *Let f, g be defined in a region $D \subset \mathbb{R} \times \mathbb{R}$ and satisfy the hypotheses of Theorem 2.5.1. Set*

$$M = \sup_{(t,u)\in D} |f(t, u) - g(t, u)|.$$

Let x and y be the solutions of the IVPs

$$x' = f(t, x),\ x(t_0) = x_0 \quad \text{and} \quad y' = g(t, y),\ y(t_0) = y_0,$$

respectively. Then the solutions x and y satisfy the estimate

$$|x(t) - y(t)| \le |x_0 - y_0|e^{K|t-t_0|} + \frac{M}{K}\Big(e^{K|t-t_0|} - 1\Big), \tag{2.5.2}$$

where K is given in the proof of Theorem 2.5.1.

Proof. Using a similar setup as in the proof of Theorem 2.5.1, we get

$$\begin{aligned}
|x(t) - y(t)| &\le |x_0 - y_0| + \int_{t_0}^{t} \Big|f(s, x(s)) - g(s, y(s))\Big|ds \\
&\le |x_0 - y_0| + \int_{t_0}^{t} \Big|f(s, x(s)) - f(s, y(s))\Big|ds \\
&\quad + \int_{t_0}^{t} \Big|f(s, x(s)) - g(s, y(s))\Big|ds \\
&\le |x_0 - y_0| + \int_{t_0}^{t} \Big[K|x(s) - y(s)| + M\Big]ds.
\end{aligned}$$

Let $U(t) = |x(t) - y(t)|$ and use an improvisation of Exercise 2.9 to obtain the estimate given by (2.5.2). This completes the proof. □

Copyright Elsevier 2022

Suppose M in Theorem 2.5.2 is small, that is, $M \leq \varepsilon > 0$. If $|t - t_0| \leq a$ for positive constant a, then inequality (2.5.2) yields

$$|x(t) - y(t)| \leq |x_0 - y_0|e^{Ka} + \frac{\varepsilon}{K}\left(e^{Ka} - 1\right),$$

and thus if $|x_0 - y_0| \leq \delta$ for some $\delta > 0$, then the two solutions remain close to each other. In other words, Theorem 2.5.2 says that if two differential equations have their right-hand sides "close together," then their solutions cannot differ very much.

2.6 Exercises

Exercise 2.1. Show that $f(t, x) = \dfrac{x}{x^2 + 1}$ is uniformly Lipschitz on $\mathbb{R}$ and identify the Lipschitz constant K.

Exercise 2.2. Compute the Lipschitz constant K for each of the functions in the regions indicated.

1. $f(t, x) = t^3 + x^4$, $\{(t, x) : |t| \leq 2, |x| \leq 3\}$.
2. $f(t, x) = t^2 \cos(x) + t \sin(x)$, $\{(t, x) : |t| \leq 2, |x| < \infty\}$.
3. $f(t, x) = t|x|$, $\{(t, x) : |t| \leq 1, |x| < \infty\}$.
4. $f(t, x) = t^2 \sin(x) \cos(x)$, $\{(t, x) : |t| \leq a, |x| < \infty\}$ for a positive constant a.
   Hint: when you perform $|f(t, x) - f(t, y)|$, add and subtract the term $\sin(x)\cos(y)$.

Exercise 2.3. Apply the Picard iterations to the IVPs

1. $x'(t) = tx$, $x(0) = 1$,
2. $x'(t) = 2t(1 + x)$, $x(0) = 2$,

and show that the obtained $\{x_n(t)\}$ of each iterate converges to the true solution of each IVP (the true solution is the solution found by solving the IVP).

Exercise 2.4. Use Theorem 2.1.2 to find the interval of existence of the unique solution of the following differential equations:

1. $x'(t) = x^2$, $x(0) = 2$.
2. $x'(t) = 5 + x^2$, $x(1) = 2$.
3. $x'(t) = x^3$, $x(0) = 2$.
4. $x'(t) = t + x^2$, $x(0) = 0$.
5. $x'(t) = 1 + x^2$, $x(0) = 0$.

Exercise 2.5. Explain why the IVP $x'(t) = tx - \sin(x)$, $x(0) = 2$, has a unique solution in the neighborhood of the point $(0, 2)$.

Copyright Elsevier 2022

Exercise 2.6. Let f be scalar and continuous in both arguments. Show that if x is a solution of the second-order differential equations $x''(t) = f(t, x(t))$, $x(t_0) = x_0$, $x'(t_0) = x_1$, then it satisfies

$$x(t) = x_0 + x_1(t - t_0) + \int_{t_0}^{t} (t - s) f(s, x(s)) ds. \tag{2.6.1}$$

Hint: Integrate twice and use the general formula

$$\int_0^t \Big[\int_0^s (g(\tau, \phi)\tau) d\tau\Big] ds = \int_0^t \Big[\int_\tau^t ds\Big] (g(\tau, \phi)\tau) d\tau.$$

Exercise 2.7. Explain why neither Theorem 2.1.2 nor Theorem 2.1.4 can be applied to the IVP

$$x'(t) = \frac{x^2}{t}, \ \ x(0) = 1.$$

Use separation of variables and find the family of solutions

$$x(t) = \frac{-1}{\text{Ln}(t) + c},$$

for some constant c. Is it possible to find c?

Exercise 2.8. Check for the existence and uniqueness of solutions of the following IVPs and sketch the corresponding rectangle D:

1. $(t - 1)x'(t) = x^2 + t$, $x(0) = 1$.
2. $(t - 1)x'(t) = x^2 + t$, $x(1) = 0$.
3. $x'(t) = t^{1/3}x + x^2$, $x(0) = 3$.
4. $(t^2 - 1)x'(t) = tx$, $x(0) = 1$.
5. $tx^2x'(t) = x^3 - t^3$, $x(1) = 1$.

Exercise 2.9. (*Generalized Gronwall's inequality*) Show that if f, u, v are nonnegative continuous functions on $[a, b]$ such that

$$u(t) \le f(t) + \int_a^t v(s)u(s)ds, \ a \le t \le b,$$

then

$$u(t) \le f(t) + \int_a^t v(s) f(s) e^{\int_s^t v(r)dr} ds, \ a \le t \le b.$$

Exercise 2.10. Find all nonnegative continuous functions $f : [0, 1] \to \mathbb{R}$ such that

$$f(t) \le \int_0^t f(s)ds, \ 0 \le t \le 1.$$

Copyright Elsevier 2022

Exercise 2.11. Let K_1, K_2 be positive constants, and let f be a nonnegative continuous function on $[a, b]$ such that

$$f(t) \le K_1 + K_2 \int_a^t f(s)ds, \; a \le t \le b.$$

Show that f satisfies

$$f(t) \le K_1 e^{K_2(b-a)}.$$

Exercise 2.12. (*Another form of Gronwall's inequality*) Let K_1, K_2 be positive constants, and let C_0 be a nonnegative constant. Suppose f is a nonnegative continuous function on $[0, h]$ such that

$$f(t) \le C_0 + \int_0^t [K_1 f(s) + K_2]ds, \; 0 \le t \le h.$$

Show that f satisfies

$$f(t) \le C_0 e^{K_1 t} + \frac{K_2}{K_1}\Big(e^{K_1 t} - 1\Big).$$

Exercise 2.13. Let x be a solution of (2.1.1) and suppose f satisfies the global Lipschitz condition with constant K for all $t \in \mathbb{R}$. Suppose that for all $t \in \mathbb{R}$, $\int_0^t |f(s,0)|ds \le M$ for positive constant M. Then $x(t)$ satisfies the inequality

$$|x(t)| \le (|x_0| + M)e^{K(t-t_0)}.$$

Exercise 2.14. Consider the system

$$x' = -x^3.$$

$$y' = -cy + x^{2\lambda} y \cos^2(y).$$

Use Gronwall's inequality to show that
(a) $y(t)$ is bounded for all $t \ge 0$ whenever $c = 0$ and $\lambda > 1$,
(b) $y(t) \to 0$ as $t \to \infty$ whenever $c > 0$ and $\lambda = 1$.

Exercise 2.15. Consider the scalar differential equation

$$x' = (a + \frac{1}{1+t}b)x, \; t \ge 0, \tag{2.6.2}$$

where a is constant. Show that if $y(t) = e^{-at}x$ and x is a solution of (2.6.2), then

$$|y(t)| \le |x(0)|e^{c\ln(1+t)} \quad \text{for some constant } c > 0.$$

In addition, show that if $a < 0$, then

$$|x(t)| \to 0 \;\text{ as }\; t \to \infty.$$

Copyright Elsevier 2022

Exercise 2.16. Let $g : [0, \infty) \to [0, \infty)$ be given by $g(x) = \frac{1}{2}e^{-x}$. Use the contraction mapping principle to prove that the graphs of g and the line $y = x$ intersect at a unique point (a, a).

Exercise 2.17. Prove Theorem 2.4.1 for $t \le 0$.

Exercise 2.18. Consider the IVP

$$x'(t) = 2tx^2,\ x(t_0) = x_0.$$

(a) Use Theorem 2.1.2 to find the largest interval of existence and uniqueness of solutions.
(b) Solve the IVP.
(c) Find the maximal interval of existence when $t_0 = 0$ and $x_0 > 0$ and find the limits at the end points.

Exercise 2.19. Consider the IVP

$$x'(t) = 2(t + 1)(1 + x^2),\ x(0) = 0.$$

(a) Solve the IVP.
(b) Find the maximal interval of existence.

Exercise 2.20. Finish the proof of Theorem 2.5.2 to obtain (2.5.2).

CHAPTER

Systems of ordinary differential equations

3

We briefly discuss how the existence and uniqueness theorems of Chapter 2 are extended to systems. Then we develop the notion of the fundamental matrix as a solution and utilize it to write solutions of non-homogeneous systems. The author made a conscious decision not to dwell too much on the topic of *Jordan canonical forms* since it is a well-developed subject in linear algebra.

3.1 Existence and uniqueness

For motivational purpose, we consider the second-order differential equation

$$x''(t) + a^2 x(t) = 0, \tag{3.1.1}$$

where a is some nonzero constant. Eq. (3.1.1) is commonly used as a model describing a mechanical process that periodically oscillates. For example, it is used to describe oscillations of a pendulum, provided that the angle change is small or of a spring with a small deflection. We use the transformation $x_1(t) = x(t)$, which is the displacement of the oscillating object. (For the pendulum, it is the angle made with the vertical.) Introducing the second transformation, the velocity or angular velocity $x_2(t) = x'(t)$, and differentiating, we get $x_1'(t) = x'(t) = x_2(t)$ and $x_2'(t) = x''(t) = -a^2 x(t) = -a^2 x_1(t)$. We therefore arrive at two first-order differential equations

$$x_1' = x_2,$$

$$x_2' = -a^2 x_1.$$

Thus we consider the general system of ordinary differential equations

$$\begin{aligned} x_1' &= f_1(t, x_1, \dots, x_n), \\ x_2' &= f_2(t, x_1, \dots, x_n), \\ &\vdots \\ x_n' &= f_n(t, x_1, \dots, x_n). \end{aligned}$$

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00009-7

Copyright Elsevier 2022

Using the vector notations

$$\mathbf{x} = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$$

and

$$f(t, \mathbf{x}) = \begin{pmatrix} f_1(t, \mathbf{x}) \\ f_2(t, \mathbf{x}) \\ \vdots \\ f_n(t, \mathbf{x}) \end{pmatrix},$$

the above system can be written in the vector form

$$\mathbf{x}' = f(t, \mathbf{x}). \tag{3.1.2}$$

Different norms on $\mathbb{R}^n$ were discussed in Chapter 1. For $\mathbf{x} = (x_1, x_2, \ldots, x_n)$, we consider the norm

$$\|\mathbf{x}\| = \sqrt{\sum_{i=1}^{n} x_i^2}.$$

However, in this section, it is more convenient to use the norm that we denote by $|\mathbf{x}|$ given by

$$|\mathbf{x}| = \sum_{i=1}^{n} |x_i|.$$

It is assumed that $|x_i|$ denotes the absolute value. The two norms are topologically equivalent in the sense that the open sets in $\mathbb{R}^n$ are the same under either norm. A set S in $\mathbb{R}^n$ is said to be open if for each $\mathbf{x}^* \in S$, there is a $\delta(\varepsilon) > 0$ such that $\mathbf{x} \in S$ whenever $|\mathbf{x} - \mathbf{x}^*| < \delta(\varepsilon)$. It can be easily shown that $\|\mathbf{x}\| \le |\mathbf{x}| \le \sqrt{n}\|\mathbf{x}\|$ for all $\mathbf{x} \in \mathbb{R}^n$. This shows the two norms are equivalent. As a direct result of this, if ϕ^i is a sequence of vector-valued functions such that for some function ϕ, $||\phi^i - \phi|| \to 0$, $i \to \infty$, then $|\phi^i - \phi| \to 0$, $i \to \infty$, and the converse holds too.

Next, we extend some definitions and theorems from Chapter 1 to systems.

Definition 3.1.1. The function $f : D \subset \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ is said to satisfy the *global* Lipschitz condition in $\mathbf{x}$ if there exists a positive constant K (called the Lipschitz constant) such that

$$|f(t, \mathbf{x}) - f(t, \mathbf{y})| \le K|\mathbf{x} - \mathbf{y}| \text{ for } (t, \mathbf{x}),\ (t, \mathbf{y}) \in D. \tag{3.1.3}$$

If for every subset $Q \subset D$, there is a positive constant K such that (3.1.3) holds, then the function f satisfies a *local* Lipschitz condition in $\mathbf{x}$. Now we discuss how to

Copyright Elsevier 2022

determine the Lipschitz constant K. Let $R \subset D$ be such that

$$R = \{(t, \mathbf{x}) : |t - t_0| \le a,\ |\mathbf{x} - \mathbf{x_0}| \le b\}$$

and assume that f and all its partial derivatives $\frac{\partial f_i}{\partial x_j}$ are continuous in R. Then the Lipschitz constant K can be defined as

$$K = \sum_{i=1}^{N} \sum_{j=1}^{N} \max_{(t,\mathbf{x}) \in R} \left| \frac{\partial f_i}{\partial x_j} \right|. \tag{3.1.4}$$

Throughout this section, we assume $f : D \to \mathbb{R}^n$ is continuous, where $D \subset \mathbb{R} \times \mathbb{R}^n$ is open.

Definition 3.1.2. Let $(t_0, \mathbf{x_0}) \in D$. We say that $x \in \mathbb{R}^n$ is a solution of the IVP

$$\mathbf{x}' = f(t, \mathbf{x}),\ \mathbf{x}(t_0) = \mathbf{x_0}, \tag{3.1.5}$$

where $\mathbf{x_0} = (x_{01}, x_{02}, \dots, x_{0n})^T$, on an interval I if $t_0 \in I$, $\mathbf{x} : I \to \mathbb{R}^n$ is differentiable, $(t, \mathbf{x}(\mathbf{t})) \in D$ for $t \in I$, $\mathbf{x}' = f(t, \mathbf{x})$ for $t \in I$, and $\mathbf{x}(t_0) = \mathbf{x_0}$.

In preparation for the next theorem we observe that the IVP (3.1.5) given in Definition 3.1.2 is equivalent to the integral relation

$$\mathbf{x}(t) = \mathbf{x_0} + \int_{t_0}^{t} f(s, \mathbf{x}(s))ds. \tag{3.1.6}$$

We have the following definition.

Definition 3.1.3. We say $\mathbf{x} : I \to \mathbb{R}^n$ is a solution of the integral equation given by (3.1.6) on an interval I if $t_0 \in I$, $\mathbf{x}$ is continuous on I, $(t, \mathbf{x}(\mathbf{t})) \in D$ for $t \in I$, and (3.1.6) is satisfied for $t \in I$.

The proof of the next theorem is identical to that of Theorem 2.1.1.

Theorem 3.1.1. *Let D be an open subset of $\mathbb{R}^{n+1}$, and let $(t_0, x_0) \in D$. Then $\mathbf{x}$ is a solution of (3.1.5) on an interval I if and only if $\mathbf{x}$ satisfies the integral equation given by (3.1.6) on I.*

Theorem 3.1.2. *(Picard's local existence and uniqueness) Let $D \subset \mathbb{R} \times \mathbb{R}^n$ be defined by*

$$D = \{(t, \mathbf{x}) : |t - t_0| \le a,\ |\mathbf{x} - \mathbf{x_0}| \le b\},$$

where a and b are positive constants. Assume that $f \in C(D, \mathbb{R}^n)$ satisfies the Lipschitz condition (3.1.3) with Lipschitz constant K given by (3.1.4). Let

$$M = \max_{(t,\mathbf{x}) \in D} |f(t, \mathbf{x})| \tag{3.1.7}$$

Copyright Elsevier 2022

and

$$h = \min\{a, \frac{b}{M}\}. \tag{3.1.8}$$

Then the IVP

$$\mathbf{x}' = f(t, \mathbf{x}),\ \mathbf{x}(t_0) = \mathbf{x_0}, \tag{3.1.9}$$

where $\mathbf{x_0} = (x_{01}, x_{02}, \dots, x_{0n})^T$*, has a unique solution, denoted by* $\mathbf{x}(t, t_0, \mathbf{x_0})$*, on the interval* $|t - t_0| \le h$ *and passing through* $(t_0, \mathbf{x_0})$ *with* $|\mathbf{x} - \mathbf{x_0}| \le b$*.*

Proof. We only give a sketch of the proof since it is identical to that of Theorem 2.1.2. Using Theorem 2.1.1 we have

$$\mathbf{x}(t) = \mathbf{x_0} + \int_{t_0}^{t} f(s, \mathbf{x}(s))ds.$$

In other words, if $\mathbf{x}(t)$ is a solution to the above integral, then it is to be understood that

$$\begin{aligned}
\mathbf{x}_1(t) &= x_{01} + \int_{t_0}^{t} f_1(s, x_1(s), \dots, x_n(s))ds,\\
\mathbf{x}_2(t) &= x_{02} + \int_{t_0}^{t} f_2(s, x_1(s), \dots, x_n(s))ds,\\
&\vdots\\
\mathbf{x}_n(t) &= x_{0n} + \int_{t_0}^{t} f_n(s, x_1(s), \dots, x_n(s))ds.
\end{aligned}$$

As for Picard's iterations, we define

$$\begin{aligned}
\mathbf{x}_{k+1,1}(t) &= x_{01} + \int_{t_0}^{t} f_1(s, x_{k,1}(s), \dots, x_{k,n}(s))ds,\\
\mathbf{x}_{k+1,2}(t) &= x_{02} + \int_{t_0}^{t} f_2(s, x_{k,1}(s), \dots, x_{k,n}(s))ds,\\
&\vdots\\
\mathbf{x}_{k+1,n}(t) &= x_{0n} + \int_{t_0}^{t} f_n(s, x_{k,1}(s), \dots, x_{k,n}(s))ds,
\end{aligned}$$

or

$$\mathbf{x}_{k+1}(t) = \mathbf{x_0} + \int_{t_0}^{t} f(s, \mathbf{x}_k(s))ds,\ k = 0, 1, \dots, n, \tag{3.1.10}$$

where

$$\mathbf{x_0} = (x_{01}, x_{02}, \dots, x_{0n})^T,$$

Copyright Elsevier 2022

and

$$\mathbf{x}_k(t) = (\mathbf{x}_{k,1}(t), \mathbf{x}_{k,2}(t), \ldots, \mathbf{x}_{k,n}(t))^T.$$

Now use (3.1.10) and Theorem 2.1.2 to finish the proof. □

To illustrate Picard's iteration, we present the following example.

Example 3.1. Consider the linear 2×2 system

$$x_1'(t) = 2x_1 - 3x_2,$$
$$x_2'(t) = x_1 - 2x_2,$$

with the initial conditions given by the vector

$$\mathbf{x}(0) = \mathbf{x_0} = \begin{pmatrix} x_{01} \\ x_{02} \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}.$$

Setting $k = 0$, the first iteration is

$$\mathbf{x}_{1,1}(t) = 1 + \int_0^t (2-3)ds = 1 - t,$$
$$\mathbf{x}_{1,2}(t) = -1 + \int_0^t (1-2)ds = -1 - t.$$

Next, setting $k = 1$ gives

$$\mathbf{x}_{2,1}(t) = 1 + \int_0^t [2(1-s) - 3(-1-s)]ds = 1 + 5t + t^2/2,$$
$$\mathbf{x}_{2,2}(t) = -1 + \int_0^t [(1-s) - 2(-1-s)]ds = -1 + 3t + t^2/2.$$

Using the method of the next section, we can show that the true solution is

$$\mathbf{x} = \begin{pmatrix} 3e^t - 2e^{-t} \\ e^t - 2e^{-t} \end{pmatrix}.$$

Remark 3.1. It is essential to know that Theorems 2.1.4, 2.2.1, 2.2.2, 2.4.1, 2.4.2, 2.4.3, and 2.5.1 can be easily extended to the IVP (3.1.9). The instructor may assign them as exercises.

Next, we consider the nth-order differential equation

$$x^{(n)}(t) = g\big(t, x, x', \ldots, x^{(n-1)}\big)$$

and use the transformation

$$x_i(t) = x^{(i-1)}(t), \quad i = 1, 2, \ldots, n$$

Copyright Elsevier 2022

to arrive at the following system:

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= x_3, \\ &\vdots \\ x_n' &= g\big(t, x_1, x_2, \dots, x_n\big). \end{aligned}$$

The right side of this system defines a vector function $f(t, \mathbf{x})$. To fully describe the solution, we impose the initial conditions

$$x^{(i-1)}(t_0) = x_{0i} \ \text{ for } \ i = 1, 2, \dots, n,$$

where x_{0i} for $i = 0, 1, \dots, n-1$ are given constants. Thus our existence and uniqueness results mean that we can impose initial conditions on the function $\mathbf{x}$ and its first $n-1$ derivatives.

Example 3.2. Consider the system

$$\begin{aligned} x_1' &= 1, \\ x_2' &= \frac{x_3}{x_1^2}, \\ x_3' &= -\frac{x_2}{x_1^2} \end{aligned}$$

with initial vector

$$\begin{pmatrix} x_1(\frac{1}{\pi}) \\ x_2(\frac{1}{\pi}) \\ x_3(\frac{1}{\pi}) \end{pmatrix} = \begin{pmatrix} \frac{1}{\pi} \\ 0 \\ -1 \end{pmatrix}.$$

Then the function

$$f(t, x) = \begin{pmatrix} 1 \\ \frac{x_3}{x_1^2} \\ -\frac{x_2}{x_1^2} \end{pmatrix}$$

is continuous with continuous partial derivatives on the set $D = \{(x_1, x_2, x_3) \in \mathbb{R}^3 : x_1 > 0\}$, and hence D is the region of existence of solutions.

To find the maximal interval, we try to solve the system. From $x_1' = 1$ we get $x_1(t) = t$, where we have applied the given initial condition. Substituting $x_1 = t$ into the second and third components of the system, and solving for t^2, we arrive at

$$\frac{x_3}{x_2'} = -\frac{x_2}{x_3'},$$

Copyright Elsevier 2022

from which we have

$$\frac{d}{dt}(x_2^2 + x_3^2) = 0, \quad \text{or} \quad x_2^2 + x_3^2 = C.$$

Applying the initial conditions, we get $C = 1$, that is,

$$x_2^2 + x_3^2 = 1.$$

It is clear that $x_2(t) = \sin(\frac{1}{t})$ and $x_3(t) = \cos(\frac{1}{t})$ satisfy $x_2^2 + x_3^2 = 1$ and the initial conditions. Thus the solution is given by

$$\mathbf{x}(t) = \begin{pmatrix} t \\ \sin(\frac{1}{t}) \\ \cos(\frac{1}{t}) \end{pmatrix},$$

and hence the maximal interval of existence is $(0, \infty)$. Note that $\lim_{t \to 0^+} \mathbf{x}(t)$ does not exist.

Theorem 3.1.3. *(Global existence) Let β be a positive constant, and let $D = \mathbb{R}^n$. Let $t_0 \geq 0$, and let $J = [t_0, \beta]$ be an interval in $\mathbb{R}$. Suppose $f : J \times D \to \mathbb{R}^n$ is continuous and satisfies the global Lipschitz condition on $J \times D$ with Lipschitz constant $k > 0$. Assume the existence of two positive continuous functions $M(t)$ and $N(t)$ such that*

$$|f(t, \mathbf{x})| \leq M(t) + N(t)|\mathbf{x}| \quad \textit{on} \quad J \times D. \tag{3.1.11}$$

Then the nonlinear initial value problem

$$\mathbf{x}' = f(t, \mathbf{x}), \ \mathbf{x}(t_0) = \mathbf{x_0} \tag{3.1.12}$$

has a unique solution on the entire interval J.

Proof. First, we show a solution $\mathbf{x} : J \to \mathbb{R}^n$ exists on $[t_0, \beta]$. Due to the continuity of the functions $M(t)$ and $N(t)$, there are two positive constants M_1 and N_1 such that $M(s) \leq M_1$ and $N(s) \leq N_1$ on $[t_0, \beta]$. Thus, for $t_0 \leq t \leq \beta$, we have that

$$\begin{aligned} |\mathbf{x}(t)| &= \Big|\mathbf{x_0} + \int_{t_0}^{t} f(s, \mathbf{x}(s))ds\Big| \\ &\leq |\mathbf{x_0}| + \int_{t_0}^{t} \big(M_1 + N_1|\mathbf{x}(s)|\big)ds \\ &\leq |\mathbf{x_0}| + M_1(\beta_1 - t_0) + \int_{t_0}^{t} N_1|\mathbf{x}(s)|ds. \end{aligned}$$

Applying Theorem 2.1.5, we arrive at the inequality

$$|\mathbf{x}(t)| \leq \big[|\mathbf{x_0}| + M_1(\beta_1 - t_0)\big]e^{N_1(\beta_1 - t_0)}.$$

Copyright Elsevier 2022

This shows $|\mathbf{x}(t)|$ is bounded on $[t_0, \beta]$. Now we show uniqueness. Suppose (3.1.12) has two solutions $\mathbf{x}(t)$ and $\mathbf{y}(t)$ and set $\mathbf{w}(t) = \mathbf{x}(t) - \mathbf{y}(t)$. Then $\mathbf{w}'(t) = \mathbf{x}'(t) - \mathbf{y}'(t)$. Therefore

$$\int_{t_0}^{t} \mathbf{w}'(s)ds = \mathbf{w}(t) - \mathbf{w}(t_0) = \int_{t_0}^{t} \Big(f(s, \mathbf{x}(s)) - f(s, \mathbf{y}(s)) \Big) ds \ \text{ with}$$

$$\mathbf{w}(t_0) = \mathbf{x}(t_0) - \mathbf{y}(t_0) = 0.$$

So we arrive at

$$\begin{aligned} |\mathbf{w}(t)| &\le \int_{t_0}^{t} |f(s, \mathbf{x}(s)) - f(s, \mathbf{y}(s))| ds \\ &\le k \int_{t_0}^{t} |\mathbf{x}(s) - \mathbf{y}(s)| ds \\ &= k \int_{t_0}^{t} |\mathbf{w}(s)| ds. \end{aligned}$$

It follows from Gronwall's inequality that $|\mathbf{w}(t)| = 0$ for all $t \in [t_0, \beta]$ and the solution is unique on $[t_0, \beta]$. This completes the proof. □

3.2 $x' = A(t)x$

Consider the linear system of ordinary differential equations of the form

$$\begin{aligned} x_1' &= a_{11}(t)x_1(t) + a_{12}(t)x_2(t) + \ldots, a_{1n}(t)x_n(t) + g_1(t), \\ x_2' &= a_{21}(t)x_1(t) + a_{22}(t)x_2(t) + \ldots, a_{2n}(t)x_n(t) + g_2(t), \\ &\ldots \\ x_n' &= a_{n1}(t)x_1(t) + a_{n2}(t)x_2(t) + \ldots, a_{nn}(t)x_n(t) + g_n(t), \end{aligned}$$

where the functions a_{ij}, g_i, $1 \le i \le n$, $1 \le j \le n$, are continuous real-valued functions on an interval I. Using vector and matrix notations, the above system is equivalent to the vector equation

$$x'(t) = A(t)x(t) + g(t), \tag{3.2.1}$$

where

$$x := \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}, \quad x' := \begin{pmatrix} x_1' \\ x_2' \\ \vdots \\ x_n' \end{pmatrix},$$

Copyright Elsevier 2022

and

$$A(t) := \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{pmatrix}, \quad g(t) := \begin{pmatrix} g_1(t) \\ g_2(t) \\ \vdots \\ g_n(t) \end{pmatrix}$$

for $t \in I$. Note that the matrix functions A and g are continuous on an interval I if and only if all their entries are continuous on I.

Definition 3.2.1. We say the $n \times 1$ vector y is a solution of (3.2.1) on I if y is continuously differentiable on I and

$$y'(t) = A(t)y(t) + g(t)$$

for all $t \in I$.

We denote the space of n-tuple continuously differentiable functions $x : I \to \mathbb{R}^n$ by $C^1(I, \mathbb{R}^n)$. Next, we define matrix norm.

Definition 3.2.2. A norm of a square matrix A is a non-negative real number denoted by $\|A\|$. There are several different ways of defining a matrix norm, but they all share the following properties:

1. $\|A\| \geq 0$ for any square matrix.
2. $\|A\| = 0$ if and only if $A = 0$ (zero matrix).
3. $\|kA\| = |k|\|A\|$ for any constant k.
4. $\|A + B\| \leq \|A\| + \|B\|$ for square matrices A and B.
5. $\|AB\| \leq \|A\|\|B\|$.

Example 3.3. Let A be a matrix with entries a_{ij}, $1 \leq i \leq n$, $1 \leq j \leq n$, that is, $A = (a_{ij})$. We define the following possible norms on the matrix A.

1. The 1-norm:

$$||A||_1 = \max_{1 \leq j \leq n} \left(\sum_{i=1}^{n} |a_{ij}| \right)$$

   (the maximum absolute column sum).
2. The infinity norm:

$$||A||_\infty = \max_{1 \leq i \leq n} \left(\sum_{j=1}^{n} |a_{ij}| \right)$$

   (the maximum of the sums of the absolute values along each row).
3. The Euclidean norm:

$$||A||_E = \sqrt{\sum_{i=1}^{n} \sum_{j=1}^{n} (a_{ij})^2}$$

   (the square root of the sum of squares of all entries).

Copyright Elsevier 2022

Note that if I is the identity matrix, then $||I||_1 = ||I||_\infty = 1$.

Next, we state and prove our first existence and uniqueness result regarding (3.2.1).

Theorem 3.2.1. *Suppose $A(t)$ and $g(t)$ are continuous on some interval $a \le t \le b$. Then* (3.2.1) *has a unique solution $\phi(t)$ on the interval $a \le t \le b$ with $\phi(t_0) = \eta$ and $a \le t_0 \le b$.*

Proof. Let $\|\cdot\|$ be a suitable matrix norm. For the existence, it suffices to show that solutions remain bounded for all $a \le t \le b$. We know from Theorem 3.1.1 that ϕ given by

$$\phi(t) = \eta + \int_{t_0}^{t} [A(s)\phi(s) + g(s)]ds$$

is a solution of (3.2.1) with $\phi(t_0) = \eta$. Let

$$K_1 = |\eta|, \ K_2 = \max_{t\in[a,b]} |g(t)|(b-a), \ \text{ and } \ K_3 = \max_{t\in[a,b]} ||A(t)||.$$

Then

$$\begin{aligned} |\phi(t)| &\le |\eta| + \left| \int_{t_0}^{t} [A(s)\phi(s) + g(s)]ds \right| \\ &\le K_1 + \int_{t_0}^{t} ||A(s)|||\phi(s)|ds + \int_{t_0}^{t} |g(s)|ds \\ &\le K_1 + \max_{t\in[a,b]} ||A(t)|| \int_{t_0}^{t} |\phi(s)|ds + \max_{t\in[a,b]} |g(t)| \int_{t_0}^{t} ds \\ &\le K_1 + K_3 \int_{t_0}^{t} |\phi(s)|ds + \max_{t\in[a,b]} |g(t)|(b-a) \\ &= \Big(K_1 + K_2\Big) + K_3 \int_{t_0}^{t} |\phi(s)|ds. \end{aligned} \tag{3.2.2}$$

Applying Theorem 2.1.5 (Gronwall's inequality) we arrive at the inequality

$$\begin{aligned} |\phi(t)| &\le \Big(K_1 + K_2\Big)e^{K_3(t-t_0)} \\ &\le \Big(K_1 + K_2\Big)e^{K_3(b-a)}. \end{aligned} \tag{3.2.3}$$

From (3.2.3) we see that solutions are bounded for all $t \in [a, b]$ and hence exist. This completes the proof of the existence. For the uniqueness, we assume the existence of two solutions ϕ_1 and ϕ_2 of (3.2.1) passing through (t_0, η). Then imitating the proof

Copyright Elsevier 2022

of the existence, we arrive at

$$\begin{aligned}|\phi_1(t)-\phi_2(t)| &\le \left|\int_{t_0}^{t} A(s)[\phi_1(s)-\phi_2(s)]ds\right| \\ &\le \int_{t_0}^{t} ||A(s)|||\phi_1(s)-\phi_2(s)|ds \\ &\le \max_{t\in[a,b]} ||A(t)|| \int_{t_0}^{t} |\phi_1(s)-\phi_2(s)|ds \\ &\le K_3 \int_{t_0}^{t} |\phi_1(s)-\phi_2(s)|ds.\end{aligned}$$

By Theorem 2.1.5 (Gronwall's inequality) it follows that

$$|\phi_1(t)-\phi_2(t)| = 0 \text{ for all } t\in[a,b],$$

and hence $\phi_1(t)=\phi_2(t)$ for all $t\in[a,b]$. The proof is complete. □

As a consequence of Theorem 3.2.1, we have the following corollary.

Corollary 3.1. *If $A(t)$ and $g(t)$ are continuous on $\mathbb{R}$, then the unique solution $\phi(t)$ of (3.2.1) is defined for all $t\in\mathbb{R}$.*

In the next discussion, we try to estimate the error between two solutions. Let ϕ_1 and ϕ_2 be two solutions of (3.2.1) with $\phi_1(t_0)=\eta_1$ and $\phi_2(t_0)=\eta_2$, respectively. Then

$$\begin{aligned}|\phi_1(t)-\phi_2(t)| &\le |\phi_1(t_0)-\phi_2(t_0)| + \left|\int_{t_0}^{t} A(s)[\phi_1(s)-\phi_2(s)]ds\right| \\ &\le |\eta_1-\eta_2| + \int_{t_0}^{t} ||A(s)|||\phi_1(s)-\phi_2(s)|ds.\end{aligned}$$

Using Gronwall's inequality, we arrive at

$$|\phi_1(t)-\phi_2(t)| \le |\eta_1-\eta_2| e^{\int_{t_0}^{t}||A(s)||ds}, \tag{3.2.4}$$

which is an estimate of the error between the two solutions at two different initial conditions.

Example 3.4. Consider the differential system

$$\begin{aligned}x_1' &= -x_2\sin(t)+4,\\ x_2' &= -x_1+2tx_2-x_3+e^t,\\ x_3' &= 3x_1\cos(t)+x_2+\frac{1}{t}x_3-5t^2.\end{aligned}$$

Copyright Elsevier 2022

Consider two solutions $\phi_1(t)$ and $\phi_2(t)$ on the interval $(1, 3)$ with initial vectors

$$\phi_1(2) = \begin{pmatrix} 7 \\ 3 \\ -2 \end{pmatrix}$$

and

$$\phi_2(2) = \begin{pmatrix} 6.7 \\ 3.2 \\ -1.9 \end{pmatrix}.$$

Next, we compute the norm of the matrix

$$A(t) = \begin{pmatrix} 0 & -\sin(t) & 0 \\ -1 & 2t & -1 \\ 3\cos(t) & 1 & 1/t \end{pmatrix}.$$

Using the 1-norm, we get

$$||A(t)|| = \max\{1 + 3|\cos(t)|, |\sin(t)| + 2t + 1, 1 + \frac{1}{t}\}$$

or

$$||A(t)|| \le \max\{4, 2 + 2t, 1 + \frac{1}{t}\} = 2 + 2t \le 8,\ 1 < t < 3.$$

Using the estimate formula given by (3.2.4), we get

$$\begin{aligned} |\phi_1(t) - \phi_2(t)| &\le (0.3 + 0.2 + 0.1)e^{\int_2^t ||A(s)||ds} \\ &\le 0.6e^{\int_2^t 8ds} \\ &\le 0.6e^{8(t-2)} < 0.6e^{8(3-2)} \approx 1790. \end{aligned}$$

Example 3.5. (*Pendulum with friction*) Fig. 3.1 shows a simple pendulum with massless string of length L and a bob of mass m acting under the external influence of gravity. Let g be the acceleration of gravity, m be the mass of the bob, L be the length of the rod, and b be the coefficient of friction (damping), which all are positive constants. The period is the time it takes for the bob to swing from its farthest right position to its left farthest position and back. Let $s(t)$ be the distance along the arc from the lowest point of the bob at time t, with displacement to the right considered positive. Let $\theta(t)$ be the corresponding angle with respect to the vertical. The gravitational force is directed downward and has the magnitude mg. The force acting in the tangential direction is $-mg\sin(\theta)$. Then the motion is modeled by the second-order differential equation

$$\frac{d^2s}{dt^2} = -g\sin(\theta).$$

Copyright Elsevier 2022

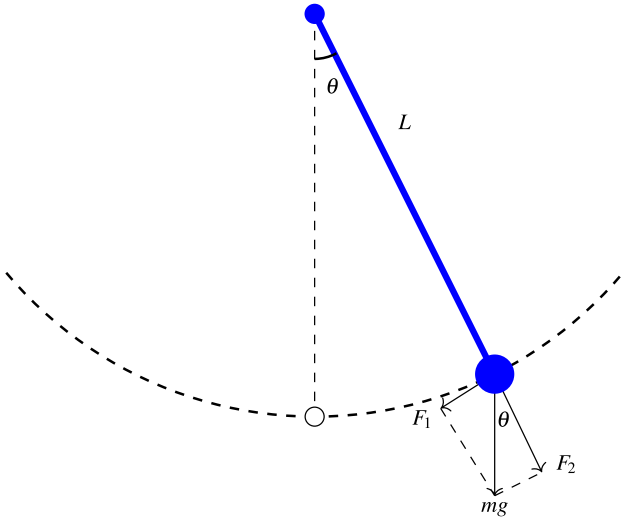

FIGURE 3.1

Pendulum with friction.

Now $s = L\theta$ as L is the radius of the circle, and so

$$\frac{d^2\theta}{dt^2} = -\frac{g}{L}\sin(\theta).$$

We add damping to the model and assume that the damping force is proportional to the velocity. As θ is our independent variable, the damping is represented as the force proportional to the angular velocity, say, $-b\dfrac{d\theta}{dt}$. The negative sign indicates that the damping force is in the opposite direction of the motion. Then the model takes the form

$$mL\theta'' + mg\sin(\theta) + bL\theta' = 0. \tag{3.2.5}$$

Assume the initial data

$$\theta(t_0) = \theta_0, \quad \theta'(t_0) = \omega_0. \tag{3.2.6}$$

To apply Theorem 2.4.4, we put (3.2.5) into a system. Thus we let $x_1(t) = \theta(t)$ and $x_2(t) = \theta'(t)$ and obtain the nonlinear two-dimensional system

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= -\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2, \end{aligned} \tag{3.2.7}$$

with corresponding initial conditions

$$x_1(t_0) = \theta_0, \quad x_2(t_0) = \omega_0. \tag{3.2.8}$$

Copyright Elsevier 2022

Let

$$f(t,x)=\begin{pmatrix} x_2 \\ -\frac{g}{L}\sin(x_1)-\frac{b}{m}x_2 \end{pmatrix}.$$

Clearly, f satisfies the global Lipschitz condition on $\mathbb{R}^2$. Thus by Theorems 2.4.3 and 2.4.4, the solution exists on some interval $[t_0,\alpha)$, $\alpha>0$. We will show that $\alpha=\infty$ by appealing to Theorem 2.4.4. Define the *energy function* $E:[t_0,\alpha)\times\mathbb{R}^2\to[0,\infty)$ by

$$E(t):=E(t,x_1,x_2)=\frac{1}{2}x_2^2(t)+\frac{g}{L}\Big(1-\cos(x_1(t))\Big). \tag{3.2.9}$$

Then along the solutions of (3.2.7) we have that

$$\begin{aligned}\frac{d}{dt}E(t)&=x_2\,x_2'+\frac{g}{L}\sin(x_1)\,x_1'\\&=x_2\Big(-\frac{g}{L}\sin(x_1)-\frac{b}{m}x_2\Big)+\frac{g}{L}\sin(x_1)x_2\\&=-\frac{b}{m}x_2^2\le 0.\end{aligned}$$

Let $t_0\le t<\alpha$ and integrate the above inequality from t_0 to t to get

$$E(t)-E(t_0)\le 0$$

or

$$E(t)\le\frac{1}{2}\omega_0^2+\frac{g}{L}\Big(1-\cos(\theta_0)\Big).$$

We have from (3.2.9) that $\frac{1}{2}x_2^2(t)\le E(t)$, so that

$$|x_2(t)|\le\sqrt{2\Big[\frac{1}{2}\omega_0^2+\frac{g}{L}\Big(1-\cos(\theta_0)\Big)\Big]}:=M.$$

Using this in the first equation of (3.2.7), after integrating, we find

$$|x_1(t)|\le|\theta_0|+M(t-t_0)\ \text{ for }\ t_0\le t<\alpha.$$

Now suppose for contradiction that $\alpha<\infty$. Then on $[t_0,\alpha)$,

$$|x_1(t)|\le|\theta_0|+M(\alpha-t_0)\ \text{ and }\ |x_2(t)|\le M.$$

Thus

$$|x|:=\sqrt{x_1^2+x_2^2}\le\sqrt{M+|\theta_0|+M(\alpha-t_0)},$$

which is bounded on $[t_0,\alpha)$. This is a contradiction to Theorem 2.4.4, and hence $\alpha=\infty$. So the maximal interval of existence is $[t_0,\infty)$. It is worth noting that the *energy function* will be referred to as a *Lyapunov function*, which we will study in more detail in Chapter 7.

Copyright Elsevier 2022

In Example 3.5 the energy function had to be chosen just right in order to yield the right results. Generally speaking, for any second-order differential equation of the form

$$x'' + f(x)x' + g(x) = 0 \tag{3.2.10}$$

and under more conditions on g, the energy function may take the form

$$E(t) := E(t, x_1, x_2) = \frac{1}{2}x_2^2(t) + \int_0^{x_1} g(s)ds \tag{3.2.11}$$

by transforming (3.2.10) into a system using the transformations

$$x_i(t) = x^{(i-1)}(t), \quad i = 1, 2.$$

On the other hand, if we do not transform (3.2.10) into a system, then we may use the energy function

$$E(t) := E(t, x) = \frac{1}{2}(x')^2 + \int_0^{x(t)} g(s)ds, \tag{3.2.12}$$

where $\frac{1}{2}(x')^2$ corresponds to the *kinetic energy*, and $\int_0^{x(t)} g(s)ds$ represents the *potential energy*.

3.2.1 Fundamental matrix

Solving the non-homogeneous equation

$$x'(t) = A(t)x(t) + g(t) \tag{3.2.13}$$

requires solving the homogeneous system

$$x'(t) = A(t)x(t), \tag{3.2.14}$$

where $A(t)$ is an $n \times n$ matrix of coefficients $a_{ij}(t)$, which are assumed to be continuous on an interval I. Recall that a solution $x(t)$ of (3.2.14) is an n-tuple of C^1 functions $x_i : I \to \mathbb{R}$. We adopt the notation

$$x(t) = \begin{pmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_n(t) \end{pmatrix}.$$

The solution x maybe considered as a C^1 vector-valued function $x : I \to \mathbb{R}^n$. The space of such functions is denoted by $C^1(I, \mathbb{R}^n)$. If $\mathscr{S}$ is the *solution space* of (3.2.14), then $\mathscr{S} \subset C^1(I, \mathbb{R}^n)$.

Copyright Elsevier 2022

Definition 3.2.3. We say that a set $\{f_1, f_2, \ldots, f_n\}$ of $n \times 1$ vector functions defined on an interval I is *linearly dependent* on I if there exist constants $c_1, c_2, \ldots, c_n$, not all zero, such that

$$c_1 f_1 + c_2 f_2 + \ldots + c_n f_n = 0$$

for every $t \in I$. If the set of functions is not *linearly dependent* on the interval I, it is said to be linearly independent.

We have the following important theorem regarding the solution space $\mathscr{S}$.

Theorem 3.2.2. *The solution space $\mathscr{S}$ is a linear vector space.*

Proof. Let $x \in C^1(I, \mathbb{R}^n)$ be a solution of (3.2.14). It is clear that $x = 0$ is a solution of (3.2.14). If $x(t_*) = 0$ for some $t_* \in I$, then $x(t) = 0$ for all $t \in I$. This is true due to the uniqueness of the solution. Thus the zero solution is in $\mathscr{S}$. Next, we show that $\mathscr{S}$ is closed under addition and scalar multiplication. Let $\phi_1(t)$ and $\phi_2(t)$ be two arbitrary functions in $\mathscr{S}$, and let c_1 c_2 be constants in $\mathbb{R}$. Set $y(t) = c_1\phi_1(t) + c_2\phi_2(t)$. Then

$$\begin{aligned} y'(t) &= (c_1\phi_1(t) + c_2\phi_2(t))' \\ &= c_1\phi_1'(t) + c_2\phi_2'(t) \\ &= c_1 A(t)\phi_1(t) + c_2 A(t)\phi_2(t) \\ &= A(t)\Big(c_1\phi_1(t) + c_2\phi_2(t)\Big) \\ &= A(t)y(t). \end{aligned}$$

Next, we show that the set of solutions of (3.2.14) is linearly independent. Let

$$\{\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\}$$

be a set of solutions of (3.2.14). We show that if $\{\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\}$ is linearly independent at some $t_* \in I$, then the set is linearly independent for all $t \in I$, that is,

$$c_1\phi_1(t) + c_2\phi_2(t) + \ldots + c_n\phi_n(t) = 0$$

only in the case $c_1 = c_2 = \ldots = c_n = 0$. Suppose the contrary, that is, there are c_i, $i = 1, 2, \ldots, n$, not all zero such that

$$c_1\phi_1(t_1) + c_2\phi_2(t_1) + \ldots + c_n\phi_n(t_1) = 0$$

for some $t_1 \in I$, $t_1 \neq t_*$. Now we use the same constants c_i to define a function for all $t \in I$,

$$x(t) = c_1\phi_1(t) + c_2\phi_2(t) + \ldots + c_n\phi_n(t). \tag{3.2.15}$$

Then by the above relation we must have $x(t_1) = 0$, since it is a solution of (3.2.14). Thus by uniqueness $x(t) = 0$ for all $t \in I$. This is a contradiction to the fact that

$$c_1\phi_1(t_*) + c_2\phi_2(t_*) + \ldots + c_n\phi_n(t_*) = 0$$

Copyright Elsevier 2022

only in the case $c_1 = c_2 = \ldots = c_n = 0$. This completes the proof of the linear independence. Left to show that $\mathscr{S}$ is an n-dimensional subspace of the vector space $C^1(I, \mathbb{R}^n)$. Let $e_1, e_2, \ldots, e_n$ be the standard basis of $\mathbb{R}^n$. Then by Corollary 3.1 there exists a set $\{\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\}$ of n solutions that form a set of solutions of (3.2.14) satisfying

$$\phi_1(t_0) = e_1, \phi_2(t_0) = e_2, \ldots, \phi_n(t_0) = e_n. \tag{3.2.16}$$

This set of solutions is linearly independent for all $t \in I$ and hence forms a linearly independent set in the solution space $\mathscr{S}$. Let $\phi(t)$ be an arbitrary solution of (3.2.14) and define

$$\phi_0 = \phi(t_0). \tag{3.2.17}$$

Now since $\phi_0 \in \mathbb{R}^n$, there are constants $c_i, i = 1, 2, \ldots, n$, not all zero, such that

$$\phi_0 = c_1 e_1 + c_2 e_2 + \ldots + c_n e_n. \tag{3.2.18}$$

Using the same constants of (3.2.18), we may define a new function $\psi : I \to \mathbb{R}^n$,

$$\psi(t) = c_1\phi_1(t) + c_2\phi_2(t) + \ldots + c_n\phi_n(t). \tag{3.2.19}$$

Since each $\phi_i, i = 1, 2, \ldots, n$, is a solution of (3.2.14), so is $\psi(t)$. By (3.2.16) and (3.2.18), we have that $\psi(t_0) = \phi_0$. This and (3.2.17) imply that ψ and ϕ have the same initial condition, and hence by the uniqueness of the solution we have that

$$\psi(t) = \phi(t) \text{ for all } t \in \mathbb{R}.$$

From (3.2.19) it follows that the arbitrary solution may be written as

$$\psi(t) = c_1\phi_1(t) + c_2\phi_2(t) + \cdots + c_n\phi_n(t),$$

which is a linear combination of the solutions $\phi_i, i = 1, 2, \ldots, n$. Therefore the set of solutions

$$\{\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\}$$

is a basis for the solution space $\mathscr{S}$. This implies that the dimension of $\mathscr{S}$ is n. This completes the proof. ☐

Definition 3.2.4. (*Fundamental set of solutions*) A set of n solutions of the linear differential system (3.2.14), all defined on the same open interval I, is called a fundamental set of solutions on I if the solutions are linearly independent functions on I.

We have the following corollary.

Corollary 3.2. *Let $A(t)$ be an $n \times n$ matrix of continuous coefficients $a_{ij}(t)$ on an interval I. If $\{\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\}$ form a fundamental set of solutions on I, then*

Copyright Elsevier 2022

the general solution of (3.2.14) *is given by*

$$x(t) = c_1\phi_1(t) + c_2\phi_2(t) + \cdots + c_n\phi_n(t)$$

with constants $c_i, i = 1, 2, \dots, n$*.*

The following definition is needed for the next theorem.

Definition 3.2.5. Let f and g be two continuous functions on $\mathbb{R}$. Then we write

$$f(x) = O\big(g(x)\big)$$

if there exists a positive real constant M and a real number x^* such

$$|f(x)| \le Mg(x) \quad \text{for all} \quad x \ge x^*.$$

Theorem 3.2.3. *If* $\{\phi_1(t), \phi_2(t), \dots, \phi_n(t)\}$ *form a fundamental set of solutions of* (3.2.14) *on* I *and* X *is the matrix function with columns* $\{\phi_1(t), \phi_2(t), \dots, \phi_n(t)\}$*, then*

$$\det X(t) = \det X(t_0) e^{\int_{t_0}^{t} \operatorname{tr}(A(s))ds} \quad \text{for } t \in I. \tag{3.2.20}$$

Proof. Let the Wronskian $w(t) := \det X(t)$. Let $t_0 \in I$ and expand $X(t)$ around t_0:

$$\begin{aligned} X(t) &= X(t_0) + (t-t_0)X'(t_0) + O\big((t-t_0)^2\big) \\ &= X(t_0) + (t-t_0)A(t_0)X(t_0) + O\big((t-t_0)^2\big) \\ &= \big[I + (t-t_0)A(t_0)\big]X(t_0) + O\big((t-t_0)^2\big). \end{aligned}$$

As a consequence, we have

$$\det X(t) = \det\Big(\big[I + (t-t_0)A(t_0)\big]\Big)\det X(t_0)$$

or

$$W(t) = \det\big[I + (t-t_0)A(t_0)\big]W(t_0).$$

By the Terence Tao matrix identity, which says

$$\det(C + hB) = \det(C) + h\operatorname{tr}\big(\operatorname{adj}(C)B\big) + O(h^2),$$

we have that

$$\det(I + (t-t_0)A(t_0))W(t_0) = W(t_0)\big[1 + (t-t_0)\operatorname{tr}\big(A(t_0)\big)\big]$$

or

$$W(t) = W(t_0)\big[1 + (t-t_0)\operatorname{tr}\big(A(t_0)\big)\big]. \tag{3.2.21}$$

Copyright Elsevier 2022

Next, we expand $W(t)$ in Taylor series around t_0:

$$W(t) = W(t_0) + (t - t_0)W'(t_0) + O\big((t - t_0)^2\big).$$

Substituting the value of $W(t)$ given by (3.2.21) into the above equality gives

$$W'(t_0) = W(t_0)\mathrm{tr}\big(A(t_0)\big).$$

Since t_0 is arbitrary, for any time $t \in \mathbb{R}$, we have the equation

$$W'(t) = W(t)\mathrm{tr}\big(A(t)\big),$$

which has the solution

$$W(t) = W(t_0)e^{\int_{t_0}^{t} \mathrm{tr}(A(s)ds} \quad \text{for } \ t \in I.$$

This completes the proof. □

Definition 3.2.6. (*Fundamental matrix*) A matrix solution Φ is called a *fundamental matrix solution* (or, shortly, fundamental matrix) of (3.2.14) on an interval I if its columns form a fundamental set of solutions. If, in addition, $\Phi(t_0) = I$, then a fundamental matrix solution is called the *principal fundamental matrix solution* (or, shortly, principal matrix).

Theorem 3.2.4. *The matrix Φ is a fundamental matrix of $x' = Ax$ at t_0 if and only if*

(a) *Φ is a solution of $x' = Ax$*
and
(b) $\det\Phi(t_0) \neq 0$.

Proof. We know that $\Phi' = A\Phi$. Let

$$\Phi = \big[\phi_1(t), \phi_2(t), \dots, \phi_n(t)\big],$$

where the columns of Φ consist of $\phi_1(t), \phi_2(t), \dots, \phi_n(t)$. Then

$$\Phi' = \big[\phi_1'(t), \phi_2'(t), \dots, \phi_n'(t)\big],$$

and

$$A\Phi = \big[A\phi_1(t), A\phi_2(t), \dots, A\phi_n(t)\big].$$

Since two matrices are equal if and only if their corresponding columns are the same,

$$\Phi'(t) = A\Phi(t)$$

Copyright Elsevier 2022

if and only if

$$x_j' = Ax_j$$

or if and only if each column of Φ is a solution.

Condition (b) is equivalent to the linear independence of

$$\phi_1(t_0), \phi_2(t_0), \ldots, \phi_n(t_0).$$

This completes the proof. □

We claim that the matrix

$$\Phi(t) = \begin{pmatrix} e^{-t} & te^{-t} \\ -e^{-t} & (1-t)e^{-t} \end{pmatrix}$$

is the fundamental matrix for the system

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -1 & -2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

To see this, we have

$$\Phi'(t) = \begin{pmatrix} -e^{-t} & e^{-t} - te^{-t} \\ e^{-t} & -e^{-t} - (1-t)e^{-t} \end{pmatrix} = \begin{pmatrix} -e^{-t} & (1-t)e^{-t} \\ e^{-t} & -2e^{-t} + te^{-t} \end{pmatrix}.$$

On the other hand,

$$\begin{pmatrix} 0 & 1 \\ -1 & -2 \end{pmatrix} \Phi = \begin{pmatrix} 0 & 1 \\ -1 & -2 \end{pmatrix} \begin{pmatrix} e^{-t} & te^{-t} \\ -e^{-t} & (1-t)e^{-t} \end{pmatrix} = \begin{pmatrix} -e^{-t} & (1-t)e^{-t} \\ e^{-t} & te^{-t} - 2e^{-t} \end{pmatrix}.$$

This proves the claim. For the next two theorems, we suppress the argument t.

Theorem 3.2.5. *If Φ is a fundamental matrix of (3.2.14), then ΦC, where C is an arbitrary $n \times n$ nonsingular constant matrix, is a fundamental matrix of (3.2.14). Conversely, if Ψ is another fundamental matrix to (3.2.14), then there exists a constant nonsingular $n \times n$ matrix C such that $\Psi = \Phi C$ for all $t \in I$.*

Proof. Let Φ be a fundamental matrix of (3.2.14) on I. Then

$$(\Phi C)' = \Phi' C = (A(t)\Phi)C = A(t)(\Phi C).$$

So ΦC solves (3.2.14). Next,

$$\det(\Phi C) = \det\Phi \det C \neq 0,$$

and by Theorem 3.2.4, ΦC is a fundamental matrix of (3.2.14). Conversely, let Φ and Ψ be two fundamental matrix solutions of (3.2.14). Since $\Phi\Phi^{-1} = I$, we have that

Copyright Elsevier 2022

$\Phi'\Phi^{-1} + \Phi(\Phi^{-1})' = 0$ or $(\Phi^{-1})' = -\Phi^{-1}\Phi'\Phi^{-1}$. Now we differentiate $\Phi^{-1}\Psi$ and obtain

$$\begin{aligned}(\Phi^{-1}\Psi)' &= (\Phi^{-1})'\Psi + \Phi^{-1}\Psi' \\ &= -\Phi^{-1}\Phi'\Phi^{-1}\Psi + \Phi^{-1}\Psi' \\ &= \big(-\Phi^{-1}A(t)\Phi\Phi^{-1} + \Phi^{-1}A(t)\big)\Psi \\ &= \big(-\Phi^{-1}A(t) + \Phi^{-1}A(t)\big)\Psi \\ &= 0.\end{aligned}$$

Therefore integrating the above expression gives $\Phi^{-1}\Psi = C$ for some $n \times n$ constant matrix C, or $\Psi = \Phi C$. Furthermore, as Ψ and Φ are fundamental matrix solutions, we have $\det\Phi \neq 0$ and $\det\Psi \neq 0$, and hence $\det C \neq 0$. This completes the proof. □

We remark that it is not true in general that $C\Phi$ is a fundamental matrix of (3.2.14).

Theorem 3.2.6. *If Φ is a fundamental matrix of* (3.2.14) *on an interval I, then Φc solves* (3.2.14) *on I for every $n \times 1$ constant vector c.*

Proof. Let Φ be a fundamental matrix of (3.2.14) on I. Then

$$(\Phi c)' = \Phi' c = (A(t)\Phi)c = A(t)(\Phi c).$$

So Φc solves (3.2.14). □

Theorem 3.2.7. *If $\Phi(t)$ is a fundamental matrix of* (3.2.14) *on an interval I, then $\Phi(t)c$ with $c = \Phi^{-1}(t_0)x_0$ is a solution of* (3.2.14) *with $x(t_0) = x_0$.*

Proof. First, $\Phi^{-1}(t_0)$ exists by the definition of a fundamental matrix. Hence by Theorem 3.2.6 $x(t) = \Phi(t)\Phi^{-1}(t_0)x_0$ solves (3.2.14). Moreover, $x(t_0) = \Phi(t_0) \times \Phi^{-1}(t_0)x_0 = Ix_0 = x_0$. This completes the proof. □

3.2.2 $x' = Ax$

Now we consider homogeneous systems with constant matrices. In particular, we look at

$$x'(t) = Ax(t), \tag{3.2.22}$$

where A is an $n \times n$ constant matrix. The fundamental solution of (3.2.22) can be constructed from a knowledge of the eigenvalues and eigenvectors of A. We begin with the following definition.

Definition 3.2.7. Let A be an $n \times n$ constant matrix, shortly, a “matrix.” A number λ is said to be an *eigenvalue* of A if there exists a nonzero vector v such that

$$Av = \lambda v. \tag{3.2.23}$$

Copyright Elsevier 2022

The solution vector v is said to be an *eigenvector* corresponding to the eigenvalue λ. We may refer to λ and v as an *eigenpair*.

Now consider a solution x of (3.2.22) of the form

$$x(t) = ve^{\lambda t}$$

for $v \in \mathbb{R}^n$ and $\lambda \in \mathbb{R}$. Then we have

$$\lambda ve^{\lambda t} = Ave^{\lambda t},$$

or

$$(A - \lambda I)v = 0 \text{ if and only if } \det(A - \lambda I) = 0.$$

Thus we have the following straightforward result.

Theorem 3.2.8. *If λ_0, v_0 is an eigenpair of A, then*

$$x(t) = e^{\lambda_0 t} v_0 = v_0 e^{\lambda_0 t}$$

is a solution of $x' = Ax$.

Proof. Let $x(t) = e^{\lambda_0 t} v_0$. Then

$$x'(t) = \lambda_0 e^{\lambda_0 t} v_0 = \lambda_0 v_0 e^{\lambda_0 t} = Av_0 e^{\lambda_0 t} = Ae^{\lambda_0 t} v_0 = Ax,$$

as desired. This completes the proof. □

Theorem 3.2.9. *(Independent eigenvectors) Let $v_1, v_2, \ldots, v_p$ be the corresponding eigenvectors to the distinct eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_p$ of a matrix A. Then $v_1, v_2, \ldots, v_p$ are linearly independent.*

Proof. Suppose $v_1, v_2, \ldots, v_j$ are linearly independent for positive integer j. If $j < p$, then v_{j+1} can be written as a linear combination of the vectors $v_1, v_2, \ldots, v_j$, that is, there are constants $c_1, c_2, \ldots, c_j$ such that

$$v_{j+1} = c_1 v_1 + c_2 v_2 + \cdots + c_j v_j.$$

Multiply from the left by the matrix A and apply the fact that $Av_i = \lambda_i v_i$ for $i = 1, 2, \ldots j$ to arrive at

$$\begin{aligned} Av_{j+1} &= \lambda_{j+1} v_{j+1} \\ &= \lambda_{j+1}\left(c_1 v_1 + c_2 v_2 + \ldots + c_j v_j\right) \\ &= c_1 \lambda_{j+1} v_1 + c_2 \lambda_{j+1} v_2 + \ldots + c_j \lambda_{j+1} v_j. \end{aligned}$$

Copyright Elsevier 2022

On the other hand,

$$\begin{aligned} Av_{j+1} &= A\big(c_1v_1 + c_2v_2 + \ldots + c_jv_j\big) \\ &= c_1Av_1 + c_2Av_2 + \ldots + c_jAv_j \\ &= c_1\lambda_1v_1 + c_2\lambda_2v_2 + \ldots + c_j\lambda_jv_j. \end{aligned}$$

Subtracting the two equations gives

$$c_1(\lambda_{j+1} - \lambda_1)v_1 + c_2(\lambda_{j+1} - \lambda_2)v_2 + \ldots + c_j(\lambda_{j+1} - \lambda_j)v_j = 0.$$

Since $v_1, v_2, \ldots, v_j$ are linearly independent, we must have that

$$c_1(\lambda_{j+1} - \lambda_1) = 0,\ c_2(\lambda_{j+1} - \lambda_2) = 0,\ \ldots,\ c_j(\lambda_{j+1} - \lambda_j) = 0.$$

Since

$$\lambda_{j+1} - \lambda_j \neq 0, \quad \text{for all} \quad j = 1, 2, \ldots, n,$$

this could only be possible if

$$c_1 = c_2, \ldots, c_j = 0.$$

This implies that

$$v_{j+1} = 0 \ \text{(zero vector)},$$

which is a contradiction, since v_{j+1} is the eigenvector corresponding to λ_{j+1}. This completes the proof. □

As a result of Definition 3.2.4, Corollary 3.2, and Theorem 3.2.9, we have the following theorem concerning systems with constant matrices such as (3.2.22).

Theorem 3.2.10. *(Distinct eigenvalues) Let* $\lambda_1, \lambda_2, \ldots, \lambda_n$ *be* n *distinct real eigenvalues of the matrix* A *of* (3.2.22)*, and let* $K_1, K_2, \ldots, K_n$ *be the corresponding eigenvectors. Then the general solution of* (3.2.22) *on the interval* $I = (-\infty, \infty)$ *is given by*

$$x(t) = c_1K_1e^{\lambda_1 t} + c_2K_2e^{\lambda_2 t}, \ldots, c_nK_ne^{\lambda_n t}$$

for constants $c_i, i = 1, 2, \ldots, n$.

Remark 3.2. If we let

$$\phi_i = K_ie^{\lambda_i t}, \quad i = 1, 2, \ldots, n,$$

then the fundamental matrix Φ of (3.2.22) is formed by taking its columns to be

$$\Phi = \big[\phi_1(t), \phi_2(t), \ldots, \phi_n(t)\big].$$

Copyright Elsevier 2022

Example 3.6. (*Distinct eigenvalues*) Consider the linear system

$$x' = \begin{pmatrix} -4 & 1 & 1 \\ 1 & 5 & -1 \\ 0 & 1 & -3 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}.$$

Then the eigenpairs are given by

$$\lambda_1 = -3, K_1 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}, \quad \lambda_2 = -4, K_2 = \begin{pmatrix} 10 \\ -1 \\ 1 \end{pmatrix}, \quad \lambda_3 = 5, K_3 = \begin{pmatrix} 1 \\ 8 \\ 1 \end{pmatrix},$$

and hence the general solution can be written as

$$x(t) = c_1 \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix} e^{-3t} + c_2 \begin{pmatrix} 10 \\ -1 \\ 1 \end{pmatrix} e^{-4t} + c_3 \begin{pmatrix} 1 \\ 8 \\ 1 \end{pmatrix} e^{5t}.$$

Moreover, the fundamental matrix $\Phi(t)$ is given by

$$\Phi(t) = \begin{pmatrix} e^{-3t} & 10e^{-4t} & e^{5t} \\ 0 & -e^{-4t} & 8e^{5t} \\ e^{-3t} & e^{-4t} & e^{5t} \end{pmatrix}. \tag{3.2.24}$$

Now suppose we impose that every solution satisfies the initial condition

$$x(t_0) := x_0 = \begin{pmatrix} x_{01} \\ x_{02} \\ x_{03} \end{pmatrix}.$$

Then by Theorem 3.2.7, the unique solution is

$$x(t) = \Phi(t)\Phi^{-1}(t_0)x_0,$$

where $\Phi(t)$ is given by (3.2.24).

Next, we discuss repeated roots. For example, the system

$$x' = \begin{pmatrix} 3 & -18 \\ 2 & -19 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \tag{3.2.25}$$

has the repeated eigenvalue $\lambda_1 = \lambda_2 = -3$. If $K_1 = \binom{k_1}{k_2}$ is the corresponding eigenvector, then we have the two equations $6k_1 - 18k_2 = 0$, $2k_1 - 6k_2 = 0$, which are both equivalent to $k_1 = 3k_2$. As a consequence, we have the single eigenvector $K_1 = \binom{3}{1}$, and so one solution is given by

$$\phi_1 = \begin{pmatrix} 3 \\ 1 \end{pmatrix} e^{-3t}.$$

Copyright Elsevier 2022

Since we are interested in finding the general solution, we need to examine the question of finding another solution.

In general, if m is a positive integer and $(\lambda - \lambda_1)^m$ is a factor of the characteristic equation $\det(A - \lambda I) = 0$, whereas $(\lambda - \lambda_1)^{m+1}$ is not a factor, then λ_1 is said to be an eigenvalue of multiplicity m. We discuss two such scenarios:

(a) For some $n \times n$ matrix A, it may be possible to find m linearly independent eigenvectors $K_1, K_2, \ldots, K_n$ corresponding to an eigenvalue λ_1 of multiplicity $m \leq n$. In this case the general solution of the system contains the linear combination

$$c_1 K_1 e^{\lambda_1 t} + c_2 K_2 e^{\lambda_2 t} + \ldots + c_n K_n e^{\lambda_n t}.$$

(b) If there is one eigenvector corresponding to an eigenvalue of multiplicity m, then we can find m linearly independent solutions of the form

$$\begin{aligned}
\phi_1 &= K_{11} e^{\lambda_1 t}, \\
\phi_2 &= K_{21} t e^{\lambda_1 t} + K_{22} e^{\lambda_1 t}, \\
&\vdots \\
\phi_m &= K_{m1} \frac{t^{m-1}}{(m-1)!} e^{\lambda_1 t} + K_{m2} \frac{t^{m-2}}{(m-2)!} e^{\lambda_1 t} + K_{mm} e^{\lambda_1 t},
\end{aligned}$$

where K_{ij} are column vectors, known as *generalized eigenvectors*. For an illustration of case (b), we suppose λ_1 is an eigenvalue of multiplicity two with only one corresponding eigenvector. To find the second eigenvector, in general, we assume a second solution of

$$x' = Ax$$

of the form

$$\phi_2(t) = K t e^{\lambda_1 t} + P e^{\lambda_1 t}, \tag{3.2.26}$$

where

$$P = \begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_n \end{pmatrix} \text{ and } K = \begin{pmatrix} k_1 \\ k_2 \\ \vdots \\ k_n \end{pmatrix}$$

are to be found. Differentiate $\phi_2(t)$ and substitute back into $x' = Ax$ to get

$$(AK - \lambda_1 K) t e^{\lambda_1 t} + (AP - \lambda_1 P - K) e^{\lambda_1 t} = 0.$$

Since this equation must hold for all t, we have

$$(A - \lambda_1 I) K = 0 \tag{3.2.27}$$

Copyright Elsevier 2022

and

$$(A - \lambda_1 I)P = K. \tag{3.2.28}$$

Eq. (3.2.27) implies that K must be an eigenvector of A associated with the eigenvalue λ_1, and hence we have one solution $\phi_1(t) = Ke^{\lambda_1 t}$. To find the second solution given by (3.2.26), we must solve for the vector P in (3.2.28). Now we go back to finding a second solution for (3.2.24). We already know K given by K_1. Let $P = \begin{pmatrix} p_1 \\ p_2 \end{pmatrix}$. Then from (3.2.28) we have $(A + 3I)P = K$, which implies that $6p_1 - 18p_2 = 3$ or $2p_1 - 6p_2 = 1$. Since these two equations are equivalent, we may choose $p_1 = 1$ and find $p_2 = 1/6$. However, for simplicity, we choose $p_1 = 1/2$, so that $p_2 = 0$. Using (3.2.26), we find that

$$\phi_2(t) = \begin{pmatrix} 3 \\ 1 \end{pmatrix} te^{-3t} + \begin{pmatrix} 1/2 \\ 0 \end{pmatrix} e^{-3t}.$$

Thus the general solution is

$$x(t) = c_1\phi_1(t) + c_2\phi_2(t) = c_1 \begin{pmatrix} 3 \\ 1 \end{pmatrix} e^{-3t} + c_2\left(\begin{pmatrix} 3 \\ 1 \end{pmatrix} te^{-3t} + \begin{pmatrix} 1/2 \\ 0 \end{pmatrix} e^{-3t}\right).$$

Moreover, the fundamental matrix $\Phi(t)$ is given by

$$\Phi(t) = \begin{pmatrix} 3e^{-3t} & 3te^{-3t} + \frac{1}{2}e^{-3t} \\ e^{-3t} & te^{-3t} \end{pmatrix}.$$

3.2.3 Exponential matrix e^{At}

In the previous section we looked at the concept of a fundamental matrix $\Phi(t)$ for the linear system $x'(t) = A(t)x(t)$ and applied it only to constant matrices. In this section we study in detail such constant matrices; namely, we consider

$$x'(t) = Ax(t), \quad x(t_0) = x_0, \tag{3.2.29}$$

where A is an $n \times n$ constant matrix, and $x \in \mathbb{R}^n$. Note that

$$||Ax - Ay|| \le K||x - y||,$$

where $K > 0$ is constant, and $||\cdot||$ is the matrix norm of A defined by

$$||A|| = \sup_{x \in \mathbb{R}^n - \{0\}} \frac{|Ax|}{|x|}.$$

Then by Picard's theorem (Theorem 3.1.2) there exists a solution on the interval $|t - t_0| < h$ for $x_0 : [-h, h] \to \mathbb{R}^n$. We may define Picard's iteration by

$$x_{n+1}(t) = x_0 + \int_{t_0}^{t} Ax_n(s)ds, \; x_0(t) = x_0, \tag{3.2.30}$$

Copyright Elsevier 2022

with the understanding that

$$x_i = (\phi_1^i, \phi_2^i, \dots, \phi_n^i)^T, \ i = 1, 2, \dots, n,$$

where $\phi_j^i \in \mathbb{R}^n$, $j = 1, 2, \dots, n$. Setting $n = 0$ in (3.2.30), we get

$$x_1 = x_0 + \int_{t_0}^{t} Ax_0 ds = x_0 + (t - t_0)Ax_0.$$

Similarly, for $n = 1$, we have

$$\begin{aligned} x_2 &= x_0 + \int_{t_0}^{t} Ax_1(s)ds = x_0 + \int_{t_0}^{t} A(s - t_0)Ax_0 ds \\ &= x_0 + (t - t_0)Ax_0 + \frac{(t - t_0)^2}{2} A^2 x_0. \end{aligned}$$

Using an induction argument, we arrive at

$$\begin{aligned} x_n &= x_0 + (t - t_0)Ax_0 + \frac{(t - t_0)^2}{2} A^2 x_0 + \ldots + \frac{(t - t_0)^n}{n!} A^n x_0 \\ &= \sum_{k=0}^{n} \frac{(t - t_0)^k}{k!} A^k x_0. \end{aligned}$$

Letting $n \to \infty$, we have

$$x(t) = e^{A(t - t_0)} x_0, \tag{3.2.31}$$

where

$$e^{A(t - t_0)} = \sum_{n=0}^{\infty} \frac{(t - t_0)^n}{n!} A^n. \tag{3.2.32}$$

It readily follows from the ratio test that the infinite series in (3.2.32) converges absolutely for all $t - t_0 \in \mathbb{R}$. Thus $e^{A(t - t_0)}$ exists for all times. Note that the infinite series given by (3.2.32) can be differentiated term by term, and hence

$$\begin{aligned} \frac{d}{dt} e^{A(t - t_0)} &= A \sum_{n=0}^{\infty} n \frac{(t - t_0)^n}{n!} A^n \\ &= \sum_{n=1}^{\infty} \frac{(t - t_0)^{n-1}}{(n - 1)!} A^n \\ &= A \sum_{n=1}^{\infty} \frac{(t - t_0)^{n-1}}{(n - 1)!} A^{n-1} \end{aligned}$$

Copyright Elsevier 2022

$$
\begin{aligned}
&= A \sum_{k=0}^{\infty} \frac{(t-t_0)^k}{k!} A^k \\
&= A e^{A(t-t_0)}.
\end{aligned}
$$

This shows that if

$$x(t) = e^{A(t-t_0)} x_0,$$

then $x(t)$ satisfies $x' = Ax$. Moreover,

$$x(t) = e^{A(t-t_0)} x_0 = \Big[I + (t-t_0)A + \frac{(t-t_0)^2}{2} A^2 + \ldots + \frac{(t-t_0)^n}{n!} A^n + \ldots \Big] x_0,$$

and hence

$$x(t_0) = I x_0 = x_0.$$

We have the following definition.

Definition 3.2.8. Let A be an $n \times n$ constant matrix. Then we define the *exponential matrix* function by $e^{A(t-t_0)}$, which is the solution of $x' = Ax$, and $e^{A(0)} = I$ (identity matrix).

Thus we have already proved that

$$x(t) = e^{A(t-t_0)} x_0 \tag{3.2.33}$$

is the unique solution of

$$x'(t) = Ax(t), \quad x(t_0) = x_0,$$

for all $t \in \mathbb{R}$.

Example 3.7. Consider the system

$$x' = \begin{pmatrix} 3 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad x(0) = \begin{pmatrix} 2 \\ -2 \end{pmatrix}.$$

Then the matrix A is diagonal and given by

$$A = \begin{pmatrix} 3 & 0 \\ 0 & -1 \end{pmatrix}.$$

Since A is a diagonal matrix, by induction we can easily show that

$$A^n = \begin{pmatrix} 3^n & 0 \\ 0 & (-1)^n \end{pmatrix}, \; n = 1, 2, \ldots.$$

Copyright Elsevier 2022

Hence

$$\begin{aligned} &I + tA + \frac{(tA)^2}{2} + \ldots + \frac{(tA)^n}{n!} \\ &\quad = \begin{pmatrix} 1 + \frac{3t}{1!} + \frac{(3t)^2}{2!} + \ldots + \frac{(3t)^n}{n!} & 0 \\ 0 & 1 + \frac{(-t)}{1!} + \frac{(-t)^2}{2!} + \ldots + \frac{(-t)^n}{n!} \end{pmatrix}. \end{aligned}$$

We deduce from the exponential function properties that the exponential matrix e^{At} is given by

$$e^{At} = \begin{pmatrix} e^{3t} & 0 \\ 0 & e^{-t} \end{pmatrix},$$

and the solution is

$$x(t) = e^{At}x_0 = \begin{pmatrix} e^{3t} & 0 \\ 0 & e^{-t} \end{pmatrix} \begin{pmatrix} 2 \\ -2 \end{pmatrix}.$$

In the next theorem we list some properties of the exponential matrix. For simplicity, we start at the initial time zero, that is, we take $t_0 = 0$. We are concerned with

$$x' = Ax, \tag{3.2.34}$$

where A is an $n \times n$ constant matrix, and $x \in \mathbb{R}^n$.

Theorem 3.2.11. *Let A and B be $n \times n$ constant matrices. Then:*

(1) $\frac{d}{dt}e^{At} = Ae^{At}$, $t \in \mathbb{R}$;
(2) $\det(e^{At}) \neq 0$, $t \in \mathbb{R}$, *and* e^{At} *is a fundamental matrix solution for* (3.2.34);
(3) $e^{At} = I + At + \frac{1}{2}(At)^2 + \frac{1}{6}(At)^3 + \cdots + \frac{1}{k!}(At)^k + \cdots$;
(4) $e^{At}e^{As} = e^{A(t+s)}$, $t, s \in \mathbb{R}$;
(5) $\left(e^{At}\right)^{-1} = e^{-At}$;
(6) *If* $AB = BA$, *then* $e^{At}B = Be^{At}$;
(7) *If* $AB = BA$, *then* $e^{At}e^{Bt} = e^{(A+Bt)}$, $t \in \mathbb{R}$;
(8) *If* P *is a nonsingular matrix, then* $e^{PBP^{-1}} = Pe^{B}P^{-1}$.

Proof. The proof of (1) is already done. For (2), we already know that e^{At} solves (3.2.34). Moreover, at $t = 0$, $e^{At} = I$, and hence $\det(e^{A0}) = \det(I) \neq 0$. By the uniqueness of solution this must hold for all $t \in \mathbb{R}$. Now since e^{At} solves (3.2.34),

Copyright Elsevier 2022

we have that e^{At} is a fundamental matrix for (3.2.34). The proof of (3) is already done. For (4), we let $L(t) = e^{At}e^{As} - e^{A(t+s)}$, where $s \in \mathbb{R}$ is fixed, and $t \in \mathbb{R}$. Then

$$L'(t) = Ae^{At}e^{As} - Ae^{A(t+s)} = A\left(e^{At}e^{As} - e^{A(t+s)}\right)$$

or $L'(t) = AL(t)$, from which we conclude that $L(t)$ solves (3.2.34). On the other hand, $L(0) = e^{As} - e^{As} = 0$, and hence by the uniqueness of solutions we get that $L(t) = 0$ for all $t \in \mathbb{R}$. This completes the proof of (4).

By the proof of (4), we have that

$$e^{At}e^{-At} = e^{At-At} = e^{A(t+(-t))} = I.$$

This implies that

$$\left(e^{At}\right)^{-1} = e^{-At}, \ t \in \mathbb{R}. \qquad \square$$

Remark 3.3. In the case where A is an $n \times n$ constant matrix, the exponential matrix is equivalent to

$$e^{A(t-t_0)} = \Phi(t)\Phi^{-1}(t_0),$$

which is the principal matrix.

Next, we discuss an important topic that relies on the *Jordan canonical form*, which helps us find the exponential matrix e^{At}. The next theorem is well known in linear algebra, and you may consult Brauer and Nohel [17] for its proof.

Theorem 3.2.12. *(Jordan canonical form) For every $n \times n$ matrix A, we can construct a matrix C such that*

$$C^{-1}AC = \begin{pmatrix} J_1 & 0 & \cdots & 0 \\ 0 & J_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & j_k \end{pmatrix}, \tag{3.2.35}$$

where

$$J_k = \lambda_k I + N_k$$

with

$$N_k = \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdots & 0 & 1 \\ 0 & 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

Copyright Elsevier 2022

Remark 3.4. (The simplest case) If A has n real and distinct eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_n$, then the matrix $C^{-1}AC$ will be a diagonal matrix with entries λ_i, that is,

$$C^{-1}AC = \begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \lambda_n \end{pmatrix}.$$

In this case the matrix C is formed from the corresponding eigenvectors of the matrix A.

If (3.2.35) holds, then let

$$B = C^{-1}AC,$$

and hence

$$e^{tA} = e^{tCBC^{-1}} = Ce^{tB}C^{-1}.$$

In Section 3.2.1, we encountered different scenarios on the type and nature of the eigenvalues when computing the eigenvectors. The next result, called *Putzer algorithm*, allows us to find the fundamental matrix or, in particular, the exponential matrix e^{At} when the matrix is constant, regardless of the order or multiplicities of the eigenvalues. Putzer's algorithm depends on the next theorem, known as the Cayley–Hamilton theorem.

Theorem 3.2.13. *(Cayley–Hamilton) Every $n \times n$ constant matrix satisfies its characteristic equation*

$$p_A(\lambda) := \det(A - \lambda I) = 0.$$

In other words, if

$$p_A(\lambda) = (-1)^n \Big(\lambda^n + c_1\lambda^{n-1} + \cdots + c_{n-1}\lambda + c_n\Big),$$

then

$$p_A(A) = (-1)^n \Big(A^n + c_1 A^{n-1} + \cdots + c_{n-1}A + c_n I\Big) = 0.$$

Theorem 3.2.14. *(Putzer algorithm) Suppose A is an $n \times n$ constant matrix with eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_n$, which may come in any order or multiplicities. Suppose $\mu_1(t), \mu_2(t), \ldots, \mu_n(t)$ satisfy the corresponding initial value problems*

$$\mu_1' = \lambda_1\mu_1,\ \mu_1(0) = 1;\ \mu_j' = \lambda_j\mu_j + \mu_{j-1},\ \mu_j(0) = 0,\ j = 2, 3, \ldots, n. \tag{3.2.36}$$

Copyright Elsevier 2022

Let the matrices $P_0, P_1, \ldots, P_n$ *be defined recursively by*

$$P_0 = I, \quad P_j = \prod_{k=1}^{j}(A - \lambda_k I), \ j = 1, 2, \ldots, n. \tag{3.2.37}$$

Then

$$e^{At} = \sum_{j=0}^{n-1} \mu_{j+1}(t) P_j. \tag{3.2.38}$$

Proof. Let

$$\Phi(t) = \sum_{j=0}^{n-1} \mu_{j+1}(t) P_j.$$

Then

$$\begin{aligned}\Phi(0) &= \sum_{j=0}^{n-1} \mu_{j+1}(0) P_j \\ &= \mu_1(0)P_0(0) + \mu_2(0)P_1(0) + \ldots + \mu_n(0)P_{n-1}(0) \\ &= \mu_1(0)P_0(0) + 0 + \ldots + 0 \ \ \text{(by (3.2.36))} \\ &= \mu_1(0)I = I \ \ \text{(by (3.2.37))}.\end{aligned}$$

Next, we differentiate Φ with respect to t:

$$\begin{aligned}\Phi'(t) &= \sum_{j=0}^{n-1} \mu'_{j+1}(t) P_j \\ &= \lambda_1 \mu_1 P_0 + \sum_{j=1}^{n-1} \mu'_{j+1}(t) P_j, \ \ \text{(by (3.2.36))} \\ &= \lambda_1 \mu_1 P_0 + \sum_{j=1}^{n-1} (\lambda_{j+1}\mu_{j+1} + \mu_j) P_j, \ \ \text{(by (3.2.36))}.\end{aligned} \tag{3.2.39}$$

On the other hand,

$$A\Phi = \sum_{j=0}^{n-1} \mu_{j+1}(t) A P_j.$$

From (3.2.37) we have

$$P_j = \prod_{k=1}^{j}(A - \lambda_k I) = (A - \lambda_j I) \prod_{k=1}^{j-1}(A - \lambda_k I) = (A - \lambda_j I) P_{j-1}.$$

Copyright Elsevier 2022

This implies that

$$AP_j = P_{j+1} + \lambda_{j+1} P_j, \quad j = 1, 2, \ldots n-1.$$

Substituting AP_j into $A\Phi$ in the above expression yields

$$A\Phi = \sum_{j=0}^{n-1} \mu_{j+1}(t)[P_{j+1} + \lambda_{j+1} I P_j],$$

$$\begin{aligned} A\Phi = {} & \lambda_1 \mu_1(t) P_0 + (\lambda_2 \mu_2(t) + \mu_1(t)) P_1 + \ldots \\ & + (\lambda_n \mu_n(t) + \mu_{n-1}(t)) P_{n-1} + \mu_n(t) P_n. \end{aligned}$$

By the Cayley–Hamilton theorem $P_n = 0$, and hence the last expression of $A\Phi$ is the same as the right side of (3.2.39) so that we have $\Phi'(t) = A\Phi(t)$ with $\Phi(0) = I$. Thus expression (3.2.38) holds by the uniqueness of the solution. This completes the proof. ☐

Example 3.8. Consider the linear system

$$x' = \begin{pmatrix} 2 & 2 & -1 \\ 2 & -1 & 2 \\ -1 & 2 & 2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$$

satisfying the initial condition

$$x(0) := x_0 = \begin{pmatrix} 1 \\ -1 \\ 2 \end{pmatrix}.$$

The matrix

$$A = \begin{pmatrix} 2 & 2 & -1 \\ 2 & -1 & 2 \\ -1 & 2 & 2 \end{pmatrix}$$

has the eigenvalues $3, 3, -3$. We may order them arbitrarily. Let, for example, $\lambda_1 = 3$, $\lambda_2 = 3$, and $\lambda_3 = -3$. Using (3.2.37) with $j = 1, 2$, we see that

$$P_0 = I, \quad P_1 = A - 3I, \quad P_2 = (A - 3I)^2.$$

Similarly, by (3.2.36)

$$\begin{aligned} \mu_1' &= 3\mu_1, \ \mu_1(0) = 1; \\ \mu_2' &= 3\mu_2 + \mu_1(t), \ \mu_2(0) = 0; \\ \mu_3' &= -3\mu_3 + \mu_2(t), \ \mu_3(0) = 0. \end{aligned}$$

Copyright Elsevier 2022

Solving the above initial value problems gives

$$\mu_1(t) = e^{3t}, \quad \mu_2(t) = te^{3t}, \quad \text{and} \quad \mu_3(t) = \frac{te^{3t}}{6} - \frac{e^{3t}}{36} + \frac{e^{-3t}}{36}.$$

By using (3.2.38) with $n = 3$, we obtain

$$e^{At} = \sum_{j=0}^{2} \mu_{j+1}(t) P_j = \mu_1 P_0 + \mu_2 P_1 + \mu_3 P_2,$$

and the unique solution is given by

$$x(t) = e^{At} x_0.$$

Example 3.9. Assume we have three masses m_1, m_2, and m_3 that are connected to each other by four springs with spring constants k_1, k_2, k_3, and k_4, respectively. As seen in Fig. 3.2, the first and last springs are attached to two fixed walls, and the masses slide along a frictionless horizontal surface. Displacement of the masses from their equilibrium positions is determined by the coordinates x, y, and z, each positive to the right. The motion of the masses depends strongly on the initial conditions, that is, by hand, any of the masses is displaced by pulling forward or backward, and we let them go. Next, we attempt to find the equations of motion. The springs operate according to Hooke's law: Force = spring constant multiplied by elongation. The springs restore after compression and extension. In addition, the first three springs are elongated by x, $y - x$, $z - y$, respectively. Then using Newton's second law, Force $=$ sum of the Hooke forces, we arrive at the system of second-order differential equations

$$\begin{aligned} m_1 x''(t) &= -k_1 x(t) + k_2[y(t) - x(t)], \\ m_2 y''(t) &= -k_2[y(t) - x(t)] + k_3[z(t) - y(t)], \\ m_3 z''(t) &= -k_3[z(t) - y(t)] - k_4 z(t). \end{aligned} \tag{3.2.40}$$

System (3.2.40) can be written as a second-order vector–matrix system

$$M\mathbf{x}''(t) = A\mathbf{x}(t),$$

where the *displacement* $\mathbf{x}$, *mass matrix* M, and *stiffness matrix* A are given by

$$\mathbf{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \quad M = \begin{pmatrix} m_1 & 0 & 0 \\ 0 & m_2 & 0 \\ 0 & 0 & m_3 \end{pmatrix}, \quad A = \begin{pmatrix} -k_1 - k_2 & k_2 & 0 \\ k_2 & -k_2 - k_3 & k_3 \\ 0 & k_3 & -k_3 - k_4 \end{pmatrix}.$$

Copyright Elsevier 2022

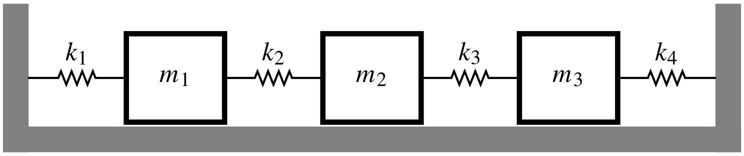

FIGURE 3.2

Three masses connected by four springs.

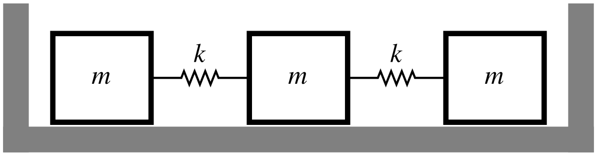

FIGURE 3.3

Three identical boxcars connected by identical springs.

Set $m_1 = m_2 = m_3 = 1$, $k_1 = 2$, $k_2 = 1$, $k_3 = 1$, and $k_4 = 2$ in the second-order vector–matrix system

$$M\mathbf{x}''(t) = A\mathbf{x}(t).$$

Then using Putzer's algorithm, we find the solution

$$\begin{aligned}\begin{pmatrix} x \\ y \\ z \end{pmatrix} &= \big(a_1 \cos(t) + b_1 \sin(t)\big) \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} \\ &+ \big(a_2 \cos(\sqrt{3}t) + b_2 \sin(\sqrt{3}t)\big) \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \\ &+ \big(a_3 \cos(2t) + b_3 \sin(2t)\big) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix},\end{aligned}$$

where a_1, a_2, b_1, b_2, a_3, and b_3 are arbitrary constants.

Example 3.10. (Boxcars) A special case of mass-spring system is *boxcars*. In Fig. 3.3 we assume three identical boxcars on a level track connected by two identical springs. Excepts for the springs on fixed ends, this problem is the same as in Example 3.9. With this in mind, we have that $k_1 = k_4 = 0$ and $k_2 = k_3 = k$. In addition, $m_1 = m_2 = m_3 = m$. Consequently, we arrive at the system

$$M\mathbf{x}''(t) = A\mathbf{x}(t),$$

Copyright Elsevier 2022

where the *displacement* $\mathbf{x}$, *mass matrix* M, and *stiffness matrix* A are given by

$$\mathbf{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \quad M = \begin{pmatrix} m & 0 & 0 \\ 0 & m & 0 \\ 0 & 0 & m \end{pmatrix}, \quad A = \begin{pmatrix} -k & k & 0 \\ k & -2k & k \\ 0 & k & -k \end{pmatrix}.$$

For illustration, we take $\frac{k}{m} = 1$. Then we have the second-order system

$$\mathbf{x}'' = \begin{pmatrix} -1 & 1 & 0 \\ 1 & -2 & 1 \\ 0 & 1 & -1 \end{pmatrix} \mathbf{x},$$

which has the vector solution

$$\begin{aligned} \begin{pmatrix} x \\ y \\ z \end{pmatrix} &= \left(a_1 + b_1 t\right) \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \\ &\quad + \left(a_2 \cos(t) + b_2 \sin(t)\right) \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \\ &\quad + \left(a_3 \cos(\sqrt{3}t) + b_3 \sin(\sqrt{3}t)\right) \begin{pmatrix} 1 \\ -2 \\ 1 \end{pmatrix}, \end{aligned}$$

where a_1, a_2, a_3, b_1, b_2, and b_3 are arbitrary constants.

3.3 $x' = A(t)x + g(t)$

Now we consider the non-homogeneous system

$$x' = A(t)x + g(t), \tag{3.3.1}$$

where $A(t)$ is an $n \times n$ matrix, and $g(t)$ is an $n \times 1$ vector, both continuous on some interval I. It was proven in Theorem 3.2.1 that system (3.3.1) has a unique solution on I if an initial condition is specified for $t_0 \in I$. We are interested in finding the *general solution* of the non-homogeneous system (3.3.1). With the non-homogeneous system we associate the complementary homogeneous system

$$x' = A(t)x. \tag{3.3.2}$$

Knowing the solution of (3.3.2) is enough to find the general solution of (3.3.1), and such a solution will be given by the *variation of parameters formula*.

Copyright Elsevier 2022

Definition 3.3.1. Let x_h be the homogeneous solution of (3.3.2), and let x_p be the particular solution of (3.3.1) on an interval I. Then the general solution $x : I \to \mathbb{R}^n$ of (3.3.1) on the interval I is given by

$$x(t) = x_h(t) + x_p(t).$$

We have seen that if Φ is the fundamental matrix of the homogeneous system (3.3.2), then $x_h = \Phi(t)k$ for some constant $n \times 1$ vector k.

Theorem 3.3.1. *Let $A(t)$ be an $n \times n$ matrix, and let $g(t)$ be an $n \times 1$ vector, both continuous on some interval I. Suppose Φ is the fundamental matrix of the homogeneous system (3.3.2). Then $x(t)$ is a solution of*

$$x' = A(t)x + g(t), \quad x(t_0) = x_0, \ t \geq t_0, \tag{3.3.3}$$

on I if and only if x satisfies

$$x(t) = \Phi(t)\Phi^{-1}(t_0)x_0 + \int_{t_0}^{t} \Phi(t)\Phi^{-1}(s)g(s)ds, \tag{3.3.4}$$

where $t_0 \in I$ and $x_0 \in \mathbb{R}^n$.

Proof. First, note that the uniqueness of the solution of (3.3.3) follows from Theorem 3.2.1. Let Φ be the fundamental matrix of the homogeneous system (3.3.2). Suppose x satisfies (3.3.4). Taking the derivative in t in (3.3.4) gives

$$\begin{aligned}
x'(t) &= \Phi'(t)\Phi^{-1}(t_0)x_0 + \Phi'(t)\int_{t_0}^{t} \Phi^{-1}(s)g(s)ds + \Phi(t)\Phi^{-1}(t)g(t) \\
&= A(t)\Phi(t)\Phi^{-1}(t_0)x_0 + A(t)\Phi(t)\int_{t_0}^{t} \Phi^{-1}(s)g(s)ds + g(t) \\
&= A(t)\Big[\Phi(t)\Phi^{-1}(t_0)x_0 + \Phi(t)\int_{t_0}^{t} \Phi^{-1}(s)g(s)ds\Big] + g(t) \\
&= A(t)x(t) + g(t).
\end{aligned}$$

Finally, replacing t by t_0 in (3.3.4) gives $x(t_0) = Ix_0 = x_0$. Now let $x(t)$ be the unique solution of (3.3.3), and let us show that it satisfies (3.3.4). As we have mentioned earlier, $x_h = \Phi(t)k$ for some constant $n \times 1$ vector k. To derive the particular solution x_p, we look for a particular solution of the form

$$x_p(t) = \Phi(t)u(t)$$

for some continuous function u on I. Differentiating x_p and plugging back into (3.3.3), we have

$$x_p' = \Phi'(t)u(t) + \Phi(t)u'(t)$$

Copyright Elsevier 2022

or

$$\Phi'(t)u(t) + \Phi(t)u'(t) = A(t)\Phi(t)u(t) + g(t).$$

Since

$$\Phi'(t) = A(t)\Phi(t),$$

the above expression reduces to

$$\Phi(t)u'(t) = g(t).$$

Multiplying the above expression by $\Phi^{-1}(t)$ from the left, we get $u'(t) = \Phi^{-1}(t)g(t)$ or $u(t) = \int_{t_0}^{t} \Phi^{-1}(s)g(s)ds$. Finally, the equality $x_p(t) = \Phi(t)u(t)$ gives

$$x_p(t) = \Phi(t)\int_{t_0}^{t} \Phi^{-1}(s)g(s)ds.$$

It follows that the general solution is

$$x(t) = x_h(t) + x_p(t) = \Phi(t)k + \int_{t_0}^{t} \Phi(t)\Phi^{-1}(s)g(s)ds. \tag{3.3.5}$$

Using the initial condition in (3.3.5), we get

$$x_0 = \Phi(t_0)k + 0$$

or

$$k = \Phi^{-1}(t_0)x_0.$$

A substitution of k into (3.3.5) gives (3.3.4). This completes the proof. ☐

Eq. (3.3.4) is called the *variation of parameters formula*.

Remark 3.5. In the case where A is an $n \times n$ constant matrix the exponential matrix is equivalent to

$$e^{A(t-t_0)} = \Phi(t)\Phi^{-1}(t_0),$$

which is the principal matrix. In this case, (3.3.4) reduces to or takes the form

$$x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^{t} e^{A(t-s)}g(s)ds. \tag{3.3.6}$$

Example 3.11. Solve

$$x'(t) = \begin{pmatrix} 4 & 2 \\ 3 & -1 \end{pmatrix} x + \begin{pmatrix} -15te^{-2t} \\ -4te^{-2t} \end{pmatrix}, \quad x(0) = \begin{pmatrix} 7 \\ 3 \end{pmatrix}.$$

Copyright Elsevier 2022

Using Putzer's algorithm, we find that

$$e^{At} = \frac{1}{7}\begin{pmatrix} e^{-2t} + 6e^{5t} & -2e^{-2t} + 2e^{5t} \\ -3e^{-2t} + 3e^{5t} & 6e^{-2t} + e^{5t} \end{pmatrix}.$$

Note that $e^{A0} = I$. Using formula (3.3.6), we have

$$\begin{aligned} x(t) &= \frac{1}{7}\begin{pmatrix} e^{-2t} + 6e^{5t} & -2e^{-2t} + 2e^{5t} \\ -3e^{-2t} + 3e^{5t} & 6e^{-2t} + e^{5t} \end{pmatrix}\begin{pmatrix} 7 \\ 3 \end{pmatrix} \\ &\quad + \int_{t_0}^{t} \frac{1}{7}\begin{pmatrix} e^{-2(t-s)} + 6e^{5(t-s)} & -2e^{-2(t-s)} + 2e^{5(t-s)} \\ -3e^{-2(t-s)} + 3e^{5(t-s)} & 6e^{-2(t-s)} + e^{5(t-s)} \end{pmatrix}\begin{pmatrix} -15se^{-2s} \\ -4se^{-2s} \end{pmatrix} ds \\ &= \frac{1}{14}\begin{pmatrix} (6 + 28t - 7t^2)e^{-2t} + 92e^{5t} \\ (-4 + 14t + 21t^2)e^{-2t} + 46e^{5t} \end{pmatrix}. \end{aligned}$$

3.4 Discussion

When the matrix A is not constant and we wish to compute the fundamental matrix of the system

$$x' = A(t)x, \tag{3.4.1}$$

where $A(t)$ is an $n \times n$ matrix with continuous components on some interval I, then the Putzer algorithm will not help much. Suppose we are able to find two matrices Λ and S such that

$$A = S\Lambda S^{-1}. \tag{3.4.2}$$

Then we claim that also

$$e^{At} = Se^{\Lambda t}S^{-1} \tag{3.4.3}$$

for all t. To prove the claim, we use (3.2.32). As a consequence of (3.4.2), we have that $At = S(\Lambda t)S^{-1}$, and hence

$$(At)^k = \big(S(\Lambda t)S^{-1}\big)\big(S(\Lambda t)S^{-1}\big)\ldots\big(S(\Lambda t)S^{-1}\big).$$

Using (3.2.32) with $t_0 = 0$, we get

$$\begin{aligned} e^{At} &= I + At + \frac{1}{2}(At)^2 + \frac{1}{6}(At)^3 + \ldots + \frac{1}{k!}(At)^k + \ldots \\ &= I + S(\Lambda t)S^{-1} + \frac{1}{2}S(\Lambda t)^2S^{-1} + \frac{1}{6}S(\Lambda t)^3S^{-1} + \ldots + \frac{1}{k!}S(\Lambda t)^kS^{-1} + \ldots \end{aligned}$$

Copyright Elsevier 2022

$$
\begin{aligned}
&= S\big[I + \Lambda t + \frac{1}{2}(\Lambda t)^2 + \frac{1}{6}(\Lambda t)^3 + \ldots + \frac{1}{k!}(\Lambda t)^k + \ldots\big]S^{-1} \\
&= Se^{\Lambda t}S^{-1},
\end{aligned}
$$

as claimed. Thus we state the general theorem.

Theorem 3.4.1. *For every $n \times n$ matrix A with entries in complex numbers, we can find an invertible matrix S and an upper triangular matrix Λ such that (3.4.2) holds.*

Another point of discussion is that if we integrate (3.4.1) from t_0 to t, then we get $x(t) = e^{\int_{t_0}^t A(s)ds}$. Now let

$$\Phi(t) = e^{\int_{t_0}^t A(s)ds}. \tag{3.4.4}$$

For $\Phi(t)$ to be fundamental matrix solution, we must have

$$A(t)\Big(\int_{t_0}^t A(s)ds\Big) = \Big(\int_{t_0}^t A(s)ds\Big)A(t). \tag{3.4.5}$$

Let us see why. Let $J = \int_{t_0}^t A(s)ds$. Then

$$e^J = I + J + \frac{1}{2!}J^2 + \frac{1}{3!}J^3 + \ldots + \frac{1}{k!}J^k + \cdots,$$

and

$$
\begin{aligned}
\frac{d}{dt}e^{\int_{t_0}^t A(s)ds} &= \frac{d}{dt}\Big(I + \int_{t_0}^t A(s)ds + \frac{1}{2!}\Big(\int_{t_0}^t A(s)ds\Big)^2 \\
&+ \ldots + \frac{1}{(k-1)!}\Big(\int_{t_0}^t A(s)ds\Big)^{k-1}A(t) + \frac{1}{k!}\Big(\int_{t_0}^t A(s)ds\Big)^k + \ldots\Big) \\
&= A(t) + \int_{t_0}^t A(s)ds\ A(t) + \frac{1}{2!}\Big(\int_{t_0}^t A(s)ds\Big)^2 A(t) \\
&+ \ldots + \frac{1}{(k-1)!}\Big(\int_{t_0}^t A(s)ds\Big)^{k-1}A(t) + \frac{1}{k!}\Big(\int_{t_0}^t A(s)ds\Big)^k A(t) + \ldots \\
&= \big[I + \int_{t_0}^t A(s)ds + \frac{1}{2!}\Big(\int_{t_0}^t A(s)ds\Big)^2 + \ldots \\
&+ \frac{1}{(k-1)!}\Big(\int_{t_0}^t A(s)ds\Big)^{k-1}A(t) + \frac{1}{k!}\Big(\int_{t_0}^t A(s)ds\Big)^k + \ldots\big]A(t) \\
&\neq A(t)\big[I + \int_{t_0}^t A(s)ds + \frac{1}{2!}\Big(\int_{t_0}^t A(s)ds\Big)^2 \\
&+ \ldots + \frac{1}{(k-1)!}\Big(\int_{t_0}^t A(s)ds\Big)^{k-1}A(t) + \frac{1}{k!}\Big(\int_{t_0}^t A(s)ds\Big)^k + \ldots\big] \\
&= A(t)\Phi(t).
\end{aligned}
$$

Copyright Elsevier 2022

Thus if (3.4.5) holds, then $\Phi'(t) = A(t)\Phi(t)$. We have the following application of the above discussion.

Example 3.12. Find the fundamental matrix $\Phi(t)$ for the system

$$x' = \begin{pmatrix} 1 & t \\ t & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Let

$$A(t) = \begin{pmatrix} 1 & t \\ t & 1 \end{pmatrix}$$

and

$$\Phi(t) = e^{\int_0^t A(s)ds}.$$

Now we verify condition (3.4.5):

$$A(t)\int_{t_0}^t A(s)ds = \begin{pmatrix} 1 & t \\ t & 1 \end{pmatrix} \begin{pmatrix} t & t^2/2 \\ t^2/2 & t \end{pmatrix} = \begin{pmatrix} t + t^3/2 & 3t^2/2 \\ 3t^2/2 & t + t^3/2 \end{pmatrix}.$$

On the other hand,

$$\Big(\int_{t_0}^t A(s)ds\Big)A(t) = \begin{pmatrix} t & t^2/2 \\ t^2/2 & t \end{pmatrix} \begin{pmatrix} 1 & t \\ t & 1 \end{pmatrix} = \begin{pmatrix} t + t^3/2 & 3t^2/2 \\ 3t^2/2 & t + t^3/2 \end{pmatrix}.$$

The matrix $\int A(t)dt$ has the eigenvalues

$$\lambda_1 = t + \frac{t^2}{2} \text{ and } \lambda_2 = t - \frac{t^2}{2}.$$

Luckily, the corresponding eigenvectors are independent of t. The eigenpairs are

$$\lambda_1, K_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix};\ \lambda_2, K_2 = \begin{pmatrix} -1 \\ 1 \end{pmatrix}.$$

Let

$$H = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

Then the inverse of H is

$$H^{-1} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

Next, we try to diagonalize $\int_0^t A(s)ds$ by the transformation

$$J = H^{-1}\Big(\int_0^t A(s)ds\Big)H := \begin{pmatrix} t + \frac{t^2}{2} & 0 \\ 0 & t - \frac{t^2}{2} \end{pmatrix}.$$

Copyright Elsevier 2022

As consequence of (3.4.3), we get the exponential matrix of J,

$$e^J = \begin{pmatrix} e^{t+\frac{t^2}{2}} & 0 \\ 0 & e^{t-\frac{t^2}{2}} \end{pmatrix}.$$

We can now calculate the fundamental matrix $\Phi(t)$:

$$\begin{aligned}\Phi(t) = e^{\int_{t_0}^{t} A(s)ds} &= He^J H^{-1} \\ &= \frac{e^t}{2}\begin{pmatrix} e^{\frac{t^2}{2}} + e^{-\frac{t^2}{2}} & e^{\frac{t^2}{2}} - e^{-\frac{t^2}{2}} \\ e^{\frac{t^2}{2}} - e^{-\frac{t^2}{2}} & e^{\frac{t^2}{2}} + e^{-\frac{t^2}{2}} \end{pmatrix}.\end{aligned}$$

3.5 Exercises

Exercise 3.1. Find the region of existence of the following system and then find the maximal interval of existence:

$$\begin{aligned} x_1' &= -\frac{x_3}{x_2^2}, \\ x_2' &= 1, \\ x_3' &= \frac{x_1}{x_2^2}, \end{aligned}$$

with initial vector

$$\begin{pmatrix} x_1(\frac{1}{\pi}) \\ x_2(\frac{1}{\pi}) \\ x_3(\frac{1}{\pi}) \end{pmatrix} = \begin{pmatrix} -1 \\ \frac{1}{\pi} \\ 0 \end{pmatrix}.$$

Exercise 3.2. Show that $||A||_1$ is a norm, that is, verify all the items in Definition 3.2.2.

Exercise 3.3. Show that if A is an $n \times n$ invertible matrix, then

$$||A|| > 0, \text{ and } ||A^{-1}|| \geq \frac{1}{||A||}.$$

Exercise 3.4. Suppose an $n \times n$ matrix $A(t)$ and an $n \times 1$ vector $g(t)$ are continuous on $-\infty < t < \infty$, $\int_{-\infty}^{\infty} |A(t)|dt < \infty$, and $\int_{-\infty}^{\infty} |g(t)|dt < \infty$. Show that the solution $\phi(t)$ of $y'(t) = A(t)y(t) + g(t)$, exists for $-\infty < t < \infty$. In addition, compute the upper bound for $|\phi(t)|$ on $-\infty < t < \infty$.

Copyright Elsevier 2022

Exercise 3.5. In Example 3.4 keep the norm of the matrix A as a function of t and obtain a slightly better estimate of the error.

Exercise 3.6. Prove that every solution of

$$x'' - x' + t^2 x = t^4$$

exists for all $t \in \mathbb{R}$.

Exercise 3.7. Use the method of *energy function* to show that the solutions

$$x'' + \cos^2(x)x' - \sin^2(x) = 0$$

exist for all times, that is, the maximal interval of existence is $[0, \infty)$.

Exercise 3.8. Obtain two iterations of the 3 × 3 linear system

$$\begin{aligned} x_1'(t) &= 5x_1 - x_2, \\ x_2'(t) &= -5x_2 + 9x_3, \\ x_3'(t) &= -5x_1 - x_2, \end{aligned}$$

with the initial condition

$$\mathbf{x}(0) = \mathbf{x_0} = \begin{pmatrix} x_{01} \\ x_{02} \\ x_{03} \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}.$$

Exercise 3.9. Use Theorem 3.2.10 to solve, for all $t \geq t_0$, the linear system

$$x' = \begin{pmatrix} 1 & -1 & 2 \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$$

with initial condition

$$x(t_0) := x_0 = \begin{pmatrix} 1 \\ 0 \\ 2 \end{pmatrix}.$$

Exercise 3.10. Use Theorem 3.2.10 to solve the linear system with the initial condition

$$x' = \begin{pmatrix} 1 & -12 & -14 \\ 1 & 2 & -3 \\ 1 & 1 & -2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}, \quad x(0) = x_0 := \begin{pmatrix} 4 \\ 6 \\ -7 \end{pmatrix}.$$

Exercise 3.11. **(a)** Let

$$x'(t) = Ax(t),$$

Copyright Elsevier 2022

where A is a constant $n \times n$ matrix. Suppose A has only one eigenvector K associated with an eigenvalue λ_1 of multiplicity three. We can find a second solution of the form (3.2.26), where the eigenvector P satisfies (3.2.28). Show that if we assume a third solution $\phi_3(t)$ of the form

$$\phi_3(t) = K\frac{t^2}{2}e^{\lambda_1 t} + Pte^{\lambda_1 t} + Qe^{\lambda_1 t},$$

then the vector Q is given by the equation

$$(A - \lambda_1 I)Q = P.$$

(b) Find the fundamental matrix for the linear system

$$x' = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 2 & -1 \\ 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}.$$

Exercise 3.12. **(a)** Let

$$x'(t) = Ax(t),$$

where A is an $n \times n$ constant matrix with real entries. Let K be an eigenvector corresponding to the complex eigenvalue $\lambda_1 = \alpha + i\beta$ (with real α and β). Show that the corresponding two linearly independent solutions $\phi_1(t)$ and $\phi_2(t)$ are given by

$$\phi_1(t) = \Big(\mathrm{Re}(K)\cos(\beta t) - \mathrm{Im}(K)\sin(\beta t)\Big)e^{\alpha t}$$

and

$$\phi_2(t) = \Big(\mathrm{Im}(K)\cos(\beta t) + \mathrm{Re}(K)\sin(\beta t)\Big)e^{\alpha t}.$$

For example, if $K = \left(\begin{smallmatrix} 1 \\ 2i \end{smallmatrix}\right)$, then

$$K = \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ 2i \end{pmatrix} = \mathrm{Re}(K) + \mathrm{Im}(K).$$

(b) Find the fundamental matrix for the linear system

$$x' = \begin{pmatrix} 1 & 2 \\ -1/2 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Exercise 3.13. Let Φ be a fundamental matrix of $x' = Ax$, and let C be a nonsingular matrix with $AC = CA$. Prove that now $C\Phi$ is a fundamental matrix of $x' = Ax$. (See Theorem 3.2.5.)

Exercise 3.14. Prove parts (5), (6), and (7) of Theorem 3.2.11.

Copyright Elsevier 2022

Exercise 3.15. Finish the calculation in Example 3.8 and show that

$$e^{At} = \cosh(3t)I + \frac{1}{3}\sinh(3t)A.$$

Exercise 3.16. Use Theorem 3.2.14 to compute e^{At} for

(a)

$$A = \begin{pmatrix} 2 & 0 & 0 \\ 1 & 2 & 0 \\ 1 & 0 & 3 \end{pmatrix},$$

(b)

$$A = \begin{pmatrix} 5 & -4 & 0 \\ 1 & 0 & 2 \\ 0 & 2 & 5 \end{pmatrix}.$$

Exercise 3.17. Use Theorem 3.2.14 to compute e^{At} for

$$x' = \begin{pmatrix} -1 & -2 & 2 \\ 3 & 5 & -3 \\ 3 & 4 & -2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$$

satisfying the initial condition

$$x(0) = x_0 := \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix}.$$

Exercise 3.18. Consider two non-homogeneous systems $x' = Ax + g_1(t)$ and $x' = Ax + g_2(t)$ with solutions z_1 and z_2, respectively. Let $g(t) = g_1(t) + g_2(t)$. Show that $z_1 + z_2$ solves $x' = Ax + g(t)$. Here g_1, g_2 are $n \times 1$ vector functions that are continuous on $\mathbb{R}$.

Exercise 3.19. Use the variation of parameters formula to solve the given system subject to the indicated initial condition.

(a)

$$x'(t) = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 3 \end{pmatrix} x + \begin{pmatrix} e^t \\ e^{2t} \\ te^{3t} \end{pmatrix}, \quad x(0) = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix},$$

(b)

$$x'(t) = \begin{pmatrix} 3 & -1 & -1 \\ 1 & 1 & -1 \\ 1 & -1 & 1 \end{pmatrix} x + \begin{pmatrix} 0 \\ t \\ 2e^t \end{pmatrix}, \quad x(0) = \begin{pmatrix} 1 \\ 2 \\ 0 \end{pmatrix}.$$

Copyright Elsevier 2022

Exercise 3.20. Imitate the proof that leads to the variation of parameters formula (1.5.2) for non-homogeneous scalar differential equations to derive (3.3.6) for the non-homogeneous system

$$x'(t) = Ax(t) + g(t), \quad x(t_0) = x_0,$$

where A is an $n \times n$ constant matrix, and g is continuous on some interval I.

Exercise 3.21. Find the fundamental matrix $\Phi(t)$ for the system

$$x' = \begin{pmatrix} -\frac{1}{t} & \frac{2}{t^2} \\ -1 & \frac{3}{t} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Exercise 3.22. Assume the fundamental matrix $\Phi(t)$ of a certain 2×2 differential system is given by

$$\Phi(t) = \begin{pmatrix} 2 & t \\ t & t^2 \end{pmatrix}.$$

Find the corresponding system of differential equations.

Exercise 3.23. Write the system

$$x_1' = -x_1 + x_2 e^{2t}, \quad x_2' = -x_2$$

in the form of

$$x'(t) = A(t)x(t).$$

Compute the eigenvalues of $A(t)$ and then find the solution of the system. Are solutions bounded or unbounded?

CHAPTER

Stability of linear systems

4

We look at the stability of linear systems via the variation of parameters. The chapter also includes a nice section on Floquet theory with its application to Mathieu's equation.

4.1 Definitions and examples

Consider the scalar differential equation

$$x' = ax, \ t \geq 0, \tag{4.1.1}$$

for constant a. Then (4.1.1) has a solution $x(t) = Ce^{at}$ for every constant C. Note that $x(t) = 0$ is a solution of (4.1.1) since it satisfies both sides of the equation. It is clear that solutions go to infinity for $a > 0$ and decay to zero for $a < 0$ as $t \to \infty$. Thus the behavior of the solutions depends on the sign of the constant a. It seems that the solution $x = 0$ is an attractor asymptotically stable in the case $a < 0$, which we will discuss in detail in this chapter.

Notice that if $a = 0$, then solutions are constants. Thus if we start near the zero solution $x = 0$, then we stay near the zero solution, and hence the zero solution is stable but not asymptotically stable.

In the above example, we were able to find the solution. However, this is not the case for the nonlinear differential equation

$$x'(t) = \frac{x(x-1)(x+2)}{1+\sin^2(x)}, \ t \geq 0, \ x(0) = x_0. \tag{4.1.2}$$

Eq. (4.1.2) is nonlinear, and the true solution cannot be explicitly found. On the other hand, we notice that $x = -2, 0, 1$ are all *constant solutions* or *equilibrium solutions* of (4.1.2). However, we can use calculus to analyze those constant solutions. Note that the right side of (4.1.2) is continuous on $\mathbb{R}$, and hence a solution exists for all $t \geq 0$. Moreover, any solution passing through (t_0, x_0) is unique. For the next discussion, we refer the reader to Fig. 4.1.

(a) For $x < -2$, we have from (4.1.2) that $x' < 0$, and hence solutions grow negatively unbounded; in particular, they pull away from the constant solution -2.

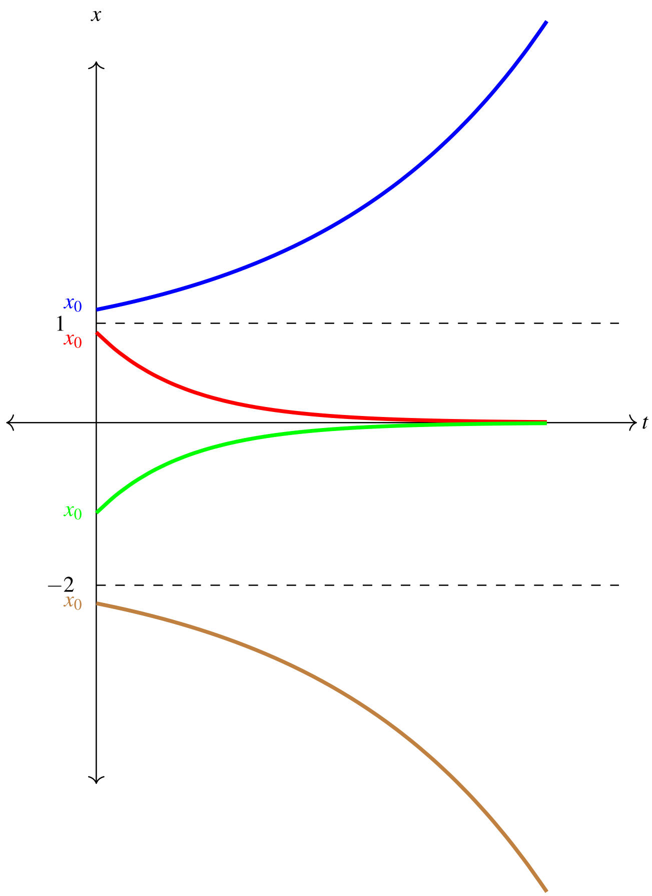

FIGURE 4.1

Diagram for the constant solutions.

- **(b)** For $-2 < x < 0$, we have from (4.1.2) that $x' > 0$, and hence solutions increase toward the constant solution $x = 0$ and away from the constant solution $x = -2$.
- **(c)** For $0 < x < 1$, we have from (4.1.2) that $x' < 0$, and hence solutions decrease toward the constant solution $x = 0$ and away from the constant solution $x = 1$. Note that in (b) and (c) solutions cannot cross the constant solution $x = 0$ due to the uniqueness. Finally,
- **(d)** For $x > 1$, we have from (4.1.2) that $x' > 0$, and hence solutions unboundedly increase and away from the constant solution $x = 1$.

Thus by the above discussion and Fig. 4.1, we see that the constant solution $x = 0$ is an attractor (asymptotically stable), and the other constant solutions $x = -2, 1$ are repellers (unstable), which we discuss later.

Copyright Elsevier 2022

Consider the system of ordinary differential equations

$$x' = f(t, x), \tag{4.1.3}$$

where $f \in C\big([0, \infty) \times D, \mathbb{R}^n\big)$, and $D \subset \mathbb{R}^n$ is open. We say that a vector $x^* \in \mathbb{R}^n$ is an *equilibrium*, or *constant solution*, or *equilibrium solution* of (4.1.3) if

$$f(t, x^*) = 0, \;\; 0 \le t < w,$$

for positive constant w. In practice, it is easier to talk about a *zero solution*, or $x = 0$. To do so, we translate every nonzero equilibrium point to zero by the change of variables

$$\tilde{x}(t) = x(t) - x^*,$$

and from (4.1.3) we have that

$$\tilde{x}'(t) = (x(t) - x^*)' = x'(t) = f(t, \tilde{x}(t) + x^*).$$

In this case, $\tilde{x}(t) \equiv 0$ is an equilibrium point of (4.1.3), which we may call the *zero solution* of (4.1.3). Thus, in most cases, we may require $f(t, 0) = 0$, $0 \le t < w$, when we talk about the zero solution.

Example 4.1. (*Lotka–Volterra predator–prey model*) Let $x(t)$ and $y(t)$ be the number of preys and predators at time t, respectively. To keep the model simple, we make the following assumptions:

- The predator species are dependent on a single prey species as its only food supply;
- The prey species have an unlimited food supply; and
- There is no threat to the prey other than the specific predator.

In the absence of predation, the prey population would grow at a natural rate:

$$\frac{dx}{dt} = ax(t), \;\; a > 0.$$

On the other hand, in the absence of prey, the predator population would decline at a natural rate:

$$\frac{dy}{dt} = -cy(t), \;\; c > 0.$$

The effects of predator eating prey is an interaction rate of decline $(-bxy, \; b > 0)$ in the prey population x and an interaction rate of growth $(dxy, \; d > 0)$ of predator population y. Hence we obtain the predator–prey model

$$\begin{aligned} \frac{dx}{dt} &= ax - bxy, \\ \frac{dy}{dt} &= -cy + dxy. \end{aligned} \tag{4.1.4}$$

Copyright Elsevier 2022

The Lotka–Volterra model consists of a system of linked differential equations that cannot be separated from each other and that cannot be solved in closed form. Thus we search for the equilibrium solutions by setting the right sides of both equations in (4.1.4) equal to zero, that is,

$$x(a - by) = 0, \quad y(-c + dx) = 0.$$

From the first equation we obtain $x = 0$, $y = a/b$, and from the second equation we get $y = 0$, $x = c/d$. Now if $x = 0$, then from the second equation we have that $-cy = 0$, and hence $y = 0$. Thus we have the equilibrium solution

$$x_1^* = (0, 0).$$

Similarly, if $y = a/b$, then $-\frac{c}{b}a + dx\frac{a}{b} = 0$, which implies that $x = c/d$. So the other equilibrium solution is

$$x_2^* = (c/d, a/b).$$

The first equilibrium solution x_1^* effectively represents the extinction of both species. If both populations are at 0, then they will continue to be so indefinitely. The second equilibrium solution x_2^* represents a fixed point at which both populations sustain their current non-zero numbers and do so indefinitely. The levels of the population at which this equilibrium is achieved depend on the chosen values of the parameters a, b, c, and d. We further discuss the stability of both equilibrium solutions x_1^* and x_2^* and hope that x_1^* is unstable. (See Fig. 4.2.)

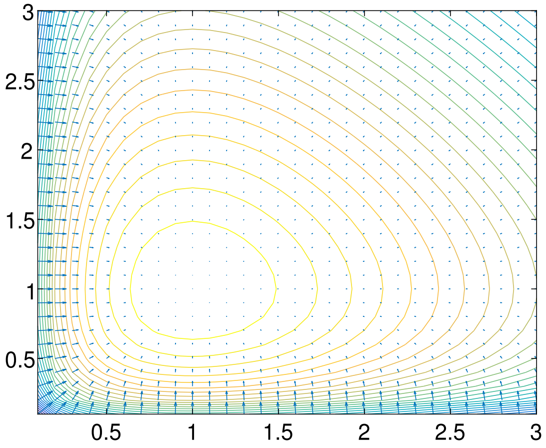

FIGURE 4.2

Prey–predator dynamics as described by the level curves. The arrows describe the velocity and direction of solutions for $a = b = c = d = 1$.

Copyright Elsevier 2022

Next, we consider (4.1.3) with the initial condition $x(t_0) = x_0$ with the assumption that $f(t, 0) = 0$.

Definition 4.1.1. The zero solution $x = 0$ of (4.1.3):

- **(a)** is *stable* (S) if for all $\varepsilon > 0$ and $t_0 \geq 0$, there is $\delta = \delta(t_0, \varepsilon) > 0$ such that $|x(t_0)| < \delta$ implies $|x(t, t_0, x_0)| < \varepsilon$,
- **(b)** is *uniformly stable* (US) if δ is independent of t_0,
- **(c)** is *unstable* if it is not stable,
- **(d)** is *asymptotically stable* (AS) if it is stable and $\lim\limits_{t\to\infty} |x(t, t_0, x_0)| = 0$.
- **(e)** is *uniformly asymptotically stable* (UAS) if it is US and there exists $\gamma > 0$ such that for each $\mu > 0$, there exists $T = T(\mu) > 0$ such that $|x(t_0)| < \gamma$, $t \geq t_0 + T$, implies $|x(t, t_0, x_0)| < \mu$.

There are various stability definitions that can be found in many of the referenced books. As far as this book is concerned, the stability definitions that we have listed are the most important ones. We furnish a few examples to illustrate the above definitions.

Example 4.2. In this example we show that the zero solution is US and AS but not UAS. We consider the initial value problem given by

$$(1-t)x'(t) = x, \; x(t_0) = x_0, \;\; t \geq t_0 > 1.$$

For simplicity, we may write our problem as

$$x' = -\frac{x}{t-1}, \; x(t_0) = x_0, \;\; t \geq t_0 > 1. \tag{4.1.5}$$

Separating the variables in (4.1.5), integrating from t_0 to t, and then applying the initial data, we arrive at the solution

$$x(t, t_0, x_0) = \frac{t_0 - 1}{t-1} x_0, \;\; t \geq t_0 > 1. \tag{4.1.6}$$

For any $\varepsilon > 0$, set $\delta = \varepsilon$, so that for $|x_0| < \delta$ and $t \geq t_0 > 1$, we have that

$$|x(t, t_0, x_0)| = \left|\frac{t_0-1}{t-1} x_0\right| = \left|\frac{t_0-1}{t-1}\right| |x_0| \leq |x_0| < \delta = \varepsilon.$$

This shows that the zero solution is US. Moreover,

$$\lim_{t\to\infty} |x(t, t_0, x_0)| = \lim_{t\to\infty} \left|\frac{t_0-1}{t-1}\right| |x_0| = 0,$$

and so the zero solution is AS. On the other hand, if we evaluate the solution $x(t, t_0, x_0) = \dfrac{t_0-1}{t-1} x_0$ at $t = t_0 + T$, then we get $x(t_0 + T, t_0, x_0) = \dfrac{t_0 - 1}{t_0 + T - 1} x_0 \to 1$ as $t_0 \to \infty$. This implies that $|x(t, t_0, x_0)| \not< \varepsilon$ for $t \geq t_0 + T$. We conclude that the zero solution is not UAS. So this example shows that US plus AS do not necessarily imply UAS.

Copyright Elsevier 2022

Example 4.3. The differential equation

$$x' = 0, \;\; x(t_0) = x_0,$$

has the constant solution $x(t) = x_0$, and hence the zero solution is US but not AS. On the other hand,

$$x' = x, \;\; x(t_0) = x_0,$$

has the solution $x(t) = x_0 e^{t-t_0}$, and its zero solution is unstable.

Example 4.4. The differential equation

$$x' = -x, \;\; x(t_0) = x_0,$$

has the solution

$$x(t, t_0, x_0) = x_0 e^{-(t-t_0)}, \;\; t \geq t_0 \geq 0,$$

and its zero solution is US and UAS. To see this, for any $\varepsilon > 0$, we set $\delta = \varepsilon$. Then for $|x_0| < \delta$, we have that $x(t, t_0, x_0)| = |x_0 e^{-(t-t_0)}| \leq |x_0| \leq \varepsilon = \delta$. So the zero solution is US. For the UAS, we must show that there exists $\gamma > 0$ such that for each $\mu > 0$, there exists $T = T(\mu) > 0$ such that $|x(t_0)| < \gamma$, $t \geq t_0 + T$, implies $|x(t, t_0, x_0)| < \mu$. Set $\delta = 1$ of the uniform stability, and let $\gamma = \delta = 1$. Let $T(\mu) > -\text{Ln}(\mu)$. Then for $t \geq t_0 + T(\mu)$,

$$|x(t, t_0, x_0)| = |x_0 e^{-(t-t_0)}| \leq e^{-T(\mu)} \leq e^{\text{Ln}(\mu)} = \mu.$$

This shows the zero solution is UAS.

4.2 $x' = A(t)x$

Now we are in a position to discuss the stability of the zero solution of the linear system

$$x'(t) = A(t)x(t), \;\; x(t_0) = x_0, \tag{4.2.1}$$

where $A(t)$ is an $n \times n$ matrix with continuous entries on $[0, \infty)$, using the concept of the fundamental matrix. We begin with the following theorem.

Theorem 4.2.1. *Let* $\Phi(t)$ *be the fundamental matrix of* (4.2.1)*. Then the zero solution of* (4.2.1) *is*

(a) *stable if and only if there exists a positive constant* M *such that*

$$|\Phi(t)| \leq M, \;\; t \geq 0;$$

(b) *asymptotically stable if and only if*

$$|\Phi(t)| \to 0 \;\; \textit{as} \;\; t \to \infty.$$

Copyright Elsevier 2022

Proof. (a) ($\Leftarrow$) Let $\Phi(t)$ be the fundamental matrix of (4.2.1). Then the unique solution x of (4.2.1) is given by $x(t) = \Phi(t)\Phi^{-1}(t_0)x_0$. Thus for any $\varepsilon > 0$ such that $|x_0| < \varepsilon$, set $\delta = \frac{\varepsilon}{|\Phi^{-1}(t_0)|M}$. Then

$$|x(t)| = |\Phi(t)\Phi^{-1}(t_0)x_0| \le |\Phi(t)||\Phi^{-1}(t_0)||x_0| \le M|\Phi^{-1}(t_0)|\delta = \varepsilon.$$

($\Rightarrow$) Set $\varepsilon = 1$ from the stability proof. Then

$$|x(t)| = |\Phi(t)\Phi^{-1}(t_0)x_0| < 1 \text{ for } t \ge t_0 \text{ if } |x_0| < \delta(1, t_0),$$

which implies that

$$|\Phi(t)\Phi^{-1}(t_0)| < \frac{1}{\delta(1, t_0)}.$$

Therefore

$$|\Phi(t)| = |\Phi(t)\Phi^{-1}(t_0)\Phi(t_0)| \le |\Phi(t)\Phi^{-1}(t_0)||\Phi(t_0)| \le \frac{1}{\delta(1, t_0)}|\Phi(t_0)| := M.$$

This completes the proof of (a).

Next, we prove (b). We already know that the zero solution is stable. Now

$$|x(t)| = |\Phi(t)\Phi^{-1}(t_0)x_0| \to 0 \text{ as } t \to \infty$$

if and only if

$$|\Phi(t)| \to 0 \text{ as } t \to \infty.$$

This completes the proof. ☐

Theorem 4.2.2. *Let $\Phi(t)$ be the fundamental matrix of* (4.2.1). *Then the zero solution of* (4.2.1) *is uniformly stable if and only if there exists a positive constant M such that*

$$|\Phi(t)\Phi^{-1}(s)| \le M, \quad t \ge s \ge 0. \tag{4.2.2}$$

Proof. ($\Leftarrow$) Let $\Phi(t)$ be the fundamental matrix of (4.2.1). Then the unique solution x of (4.2.1) is given by $x(t) = \Phi(t)\Phi^{-1}(s)x(s)$. Since (4.2.2) holds for all s such that $t \ge s \ge 0$, we have that

$$|x(t)| = |\Phi(t)\Phi^{-1}(s)x(s)| \le |\Phi(t)\Phi^{-1}(s)||x_0|.$$

Thus for any $\varepsilon > 0$, choosing $\delta = \frac{\varepsilon}{M}$, we get that for $|x_0| < \delta$,

$$|x(t)| \le |\Phi(t)||\Phi^{-1}(s)||x_0| \le M\delta = \varepsilon.$$

($\Rightarrow$) Set $\varepsilon = 1$ from the proof of uniform stability. Then

$$|x(t)| = |\Phi(t)\Phi^{-1}(s)x(s)| < 1 \text{ for } t \ge s \text{ if } |x(s)| < \delta(1),$$

Copyright Elsevier 2022

which implies that

$$|\Phi(t)\Phi^{-1}(s)| \le \frac{1}{\delta(1)} := M.$$

This completes the proof. □

The next theorem provides necessary and sufficient conditions for the UAS.

Theorem 4.2.3. *Let $\Phi(t)$ be the fundamental matrix of* (4.2.1). *Then the zero solution of* (4.2.1) *is uniformly asymptotically stable if and only if there exist positive constants M and β such that*

$$|\Phi(t)\Phi^{-1}(s)| \le Me^{-\beta(t-s)}, \ \ t \ge s \ge 0. \tag{4.2.3}$$

Proof. ($\Leftarrow$) Let $\Phi(t)$ be the fundamental matrix of (4.2.1). Then the unique solution x of (4.2.1) is given by $x(t) = \Phi(t)\Phi^{-1}(s)x(s)$. It is evident from (4.2.3) that the zero solution is US. For all $t \ge s \ge 0$, we have that

$$|x(t)| = |\Phi(t)\Phi^{-1}(s)x(s)| \le |\Phi(t)\Phi^{-1}(s)||x_0|.$$

As a result, we may set $\gamma = 1$. Now we take $T(\mu) = -\frac{1}{\beta}\mathrm{Ln}(\frac{\mu}{M})$, $0 < \mu < M$. Then for $|x_0| < 1$ and $t \ge t_0 + T(\mu)$, we have

$$|x(t)| = |\Phi(t)\Phi^{-1}(t_0)x_0| < Me^{-\beta(t-t_0)} = Me^{-\beta T(\mu)} \le \mu.$$

($\Rightarrow$) Since the zero solution is UAS, there exists $\gamma > 0$ such that for each $\mu > 0$, there exists $T = T(\mu) > 0$ such that $|x(t_0)| < \gamma$, $t \ge t_0 + T$, implies $|x(t, t_0, x_0)| < \mu$. Let $\alpha = \frac{\mu}{\gamma}$. Then $|x_0| \le \gamma$ and $t \ge t_0 + T(\mu)$ yield

$$|\Phi(t)\Phi^{-1}(t_0)x_0| \le \mu. \tag{4.2.4}$$

Therefore

$$|\Phi(t + T(\mu))\Phi^{-1}(t)| \le \alpha < 1, \ t \ge 0. \tag{4.2.5}$$

For $t \ge t_0$, there is a positive integer k such that

$$t_0 + kT(\mu) \le t \le t_0 + (k+1)T(\mu).$$

Now let $t_n = t_0 + (k+1)T(\mu)$, $n = 1, 2, \dots, k$. Then by (4.2.4) and (4.2.5)

$$\begin{aligned} |\Phi(t)\Phi^{-1}(t_0)| &= \left|\Phi(t)\Phi^{-1}(t_k)\Phi(t_k)\Phi^{-1}(t_{k-1})\dots\Phi(t_1)\Phi^{-1}(t_0)\right| \\ &\le \left|\Phi(t)\Phi^{-1}(t_k)\right| \prod_{n=0}^{k-1} \Phi(t_{n+1})\Phi^{-1}(t_n) \\ &\le M\alpha^k. \end{aligned}$$

Copyright Elsevier 2022

Let $\beta = -\frac{1}{T(\gamma)}\text{Ln}(\alpha) > 0$. Then

$$\begin{aligned}
|\Phi(t)\Phi^{-1}(t_0)| &\le \frac{M}{\alpha}\alpha^{k+1} \\
&= \frac{M}{\alpha}e^{-(k+1)\beta T(\gamma)} \\
&\le \frac{M}{\alpha}e^{-\beta(t-t_0)} \\
&:= Le^{-\beta(t-t_0)}.
\end{aligned}$$

This completes the proof. □

Example 4.5. The nonlinear system

$$x'(t) = \begin{pmatrix} 0 & 1 \\ \frac{-2}{t^2} & \frac{2}{t} \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \; t > 0,$$

has the fundamental matrix

$$\Phi(t) = \begin{pmatrix} t^2 & t \\ 2t & 1 \end{pmatrix}, \; t > 0.$$

By Theorem 4.2.1, its zero solution is unstable, since there is no constant M such that $||\Phi(t)|| \le M$.

Example 4.6. The system

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -2 & -2 \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \; t > 0,$$

has the fundamental matrix

$$\Phi(t) = e^{-t}\begin{pmatrix} \cos(t) & \sin(t) \\ -(\cos(t) + \sin(t)) & \cos(t) - \sin(t) \end{pmatrix}, \; t > 0.$$

After some calculations, we can verify that for some positive constant K,

$$||\Phi(t)\Phi^{-1}(s)|| \le Ke^{-(t-s)}, \; t \ge s \ge 0,$$

and by Theorem 4.2.3 the zero solution is UAS.

4.3 Floquet theory

This section is concerned with homogeneous systems of the form

$$x'(t) = A(t)x(t), \tag{4.3.1}$$

Copyright Elsevier 2022

where the matrix $A(t)$ is periodic with period T (constant), that is,

$$A(t+T) = A(t) \text{ for all } t \in \mathbb{R}.$$

For the rest of this section, we assume that $A(t)$ is a periodic matrix with period T. Our aim is to find an expression for the fundamental matrix in this case. Unlike the case of a constant coefficient matrix, the fundamental matrix cannot be expressed as $\Phi(t) = (\phi_1, \dots, \phi_n)$ where the ϕ_i, $i = 1, 2, \dots, n$, satisfy

$$\phi_i(t) = k_i e^{\lambda_i t},$$

and (λ_i, K_i), $i = 1, 2, \dots n$, is eigenpairs for the constant matrix A. To reinforce this notion, we offer the following example.

Example 4.7. Consider the nonlinear system

$$x'(t) = \begin{pmatrix} \sin(t) & 0 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ t \in \mathbb{R}.$$

Then the corresponding $A(t)$ matrix is periodic with period $T = 2\pi$. Moreover, $A(t)$ has the eigenpairs

$$\big(\sin(t), \begin{pmatrix} 1 \\ 0 \end{pmatrix}\big), \big(2, \begin{pmatrix} 0 \\ 1 \end{pmatrix}\big).$$

Without thinking and not paying attention to the fact that A is not a constant matrix, using the obtained eigenpairs, we form the fundamental matrix

$$\Phi(t) = \begin{pmatrix} e^{\sin(t)} & 0 \\ 0 & e^{2t} \end{pmatrix}.$$

It is clear that the first column $\phi_1(t) = \begin{pmatrix} e^{\sin(t)} \\ 0 \end{pmatrix}$ is not a vector solution of the system since

$$\begin{pmatrix} \sin(t) & 0 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} e^{\sin(t)} \\ 0 \end{pmatrix} = \begin{pmatrix} \sin(t) e^{\sin(t)} \\ 0 \end{pmatrix} \neq \phi_1'(t).$$

In other words,

$$A(t)\phi_1(t) \neq \phi_1'(t).$$

Hence we cannot use the eigenpairs to obtain the fundamental matrix for the periodic differential system.

Example 4.7 is a living proof of the need to develop a new approach to find the fundamental matrix of systems in the form (4.3.1). To motivate the subject, we consider the scalar differential equation

$$x'(t) = a(t)x(t), \tag{4.3.2}$$

Copyright Elsevier 2022

where $a : \mathbb{R} \to \mathbb{R}$ is continuous and periodic with minimal period T. Then every solution $\phi(t)$ of (4.3.2) has the form

$$\phi(t) = ce^{\int_0^t a(s)ds}. \tag{4.3.3}$$

Set the constant $c = 1$, and for a constant λ, we observe that

$$\int_t^{t+T} a(s)ds = \lambda T, \quad \text{a constant},$$

for all $t \in \mathbb{R}$, since $a(t+T) = a(t)$. Using (4.3.3) with $c = 1$, we have

$$\phi(t+T) = e^{\int_0^{t+T} a(s)ds} = e^{\int_0^t a(s)ds} e^{\int_t^{t+T} a(s)ds} = \phi(t)e^{\lambda t}. \tag{4.3.4}$$

The number λ in (4.3.4) has a profound effect on the behavior of the solution ϕ. At a glance, if ϕ is periodic with period T, that is, $\phi(t+T) = \phi(t)$, then (4.3.4) implies that

$$e^{\lambda t} = 1.$$

This holds if and only if $\lambda = \frac{2\pi i}{T}$. The number λ is called a *characteristic exponent* for (4.3.2), and $e^{\lambda t}$ is called the corresponding *characteristic multiplier*. More information about the form of the solutions can be revealed by letting the new function

$$p(t) = \phi(t)e^{-\lambda t}.$$

Then the function p is periodic with period T since

$$p(t+T) = \phi(t+T)e^{-\lambda(t+T)} = \phi(t)e^{\lambda T}e^{-\lambda(t+T)} = \phi(t)e^{-\lambda t} = p(t).$$

Thus any solution of (4.3.2) can be written in the form

$$\phi(t) = p(t)e^{\lambda t}. \tag{4.3.5}$$

Eq. (4.3.5) is very significant in the sense that it allows us to study the behavior of all solutions on $-\infty < t < +\infty$. As noted above, ϕ is periodic with period T if and only if $\lambda = \frac{2n\pi i}{T}$. Similarly, $\phi(t) \to 0$ as $t \to \infty$ and becomes unbounded as $t \to -\infty$ if and only if $\operatorname{Re}\lambda < 0$.

Now we go back to the periodic system (4.3.1).

Theorem 4.3.1. *Let $A(t+T) = A(t)$ for all $t \in \mathbb{R}$. If $\Phi(t)$ is a fundamental matrix of (4.3.1), then so is $\Phi(t+T)$, and there exists a nonsingular constant matrix B such that*

(a) $\Phi(t+T) = \Phi(t)B$ *for all* $t \in \mathbb{R}$*;*

(b) $\det\big(B\big) = e^{\int_0^t \operatorname{tr}\big(A(s)\big)ds}$.

Copyright Elsevier 2022

Proof. (a) Set $Z(t) = \Phi(t+T)$. Then

$$Z'(t) = \Phi'(t+T) = A(t+T)\Phi(t+T) = A(t)\Phi(t+T) = Z(t)\Phi(t+T).$$

Moreover, $\det\big(Z(t)\big) = \det\big(\Phi(t+T)\big) \neq 0$, since $\Phi(t)$ is a fundamental matrix. This proves that $\Phi(t+T)$ is also a fundamental matrix. The second part of (a) follows from Theorem 3.2.5. This completes the proof of (a). For the proof of (b), we let $W(t) = \det\big(\Phi(t)\big)$. From Theorem 3.2.3 we have that

$$W(t) = W(t_0)e^{\int_{t_0}^{t} \mathrm{tr}\big(A(s)\big)ds},$$

and hence

$$\begin{aligned} W(t+T) &= W(t_0)e^{\int_{t_0}^{t+T} \mathrm{tr}(A(s))ds} \\ &= W(t_0)e^{\left(\int_{t_0}^{t} \mathrm{tr}\big(A(s)\big)ds + \int_{t}^{t+T} \mathrm{tr}\big(A(s)\big)ds\right)} \\ &= W(t_0)e^{\int_{t_0}^{t} \mathrm{tr}\big(A(s)\big)ds} \cdot e^{\int_{t}^{t+T} \mathrm{tr}\big(A(s)\big)ds} \\ &= W(t)e^{\int_{0}^{T} \mathrm{tr}\big(A(s)\big)ds}. \end{aligned} \tag{4.3.6}$$

In addition,

$$\Phi(t+T) = \Phi(t)B$$

or

$$\det\big(\Phi(t+T)\big) = \det\big(\Phi(t)\big)\det\big(B\big).$$

Thus

$$W(t+T) = W(t)\det(B\big). \tag{4.3.7}$$

A comparison of (4.3.6) and (4.3.7) gives

$$\det(B\big) = e^{\int_{0}^{T} \mathrm{tr}\big(A(s)\big)ds}.$$

□

Remark 4.1. Note that since the matrix B is constant, we can uniquely determine it by evaluating both sides of (a) at $t = 0$:

$$B = \Phi^{-1}(0)\Phi(T).$$

We have the following definition of Floquet multipliers.

Definition 4.3.1. Let $\Phi(t)$ be the fundamental matrix for the Floquet system (4.3.1). Then the eigenvalues $\rho_1, \rho_2, \ldots, \rho_n$ of

Copyright Elsevier 2022

$$B := \Phi^{-1}(0)\Phi(T)$$

are called the *Floquet multipliers* of the Floquet system (4.3.1).

The *Floquet exponents* are $\mu_1, \mu_2, \dots, \mu_n$ satisfying

$$\rho_1 = e^{\mu_1 T}, \rho_2 = e^{\mu_2 T}, \dots, \rho_n = e^{\mu_n T}. \tag{4.3.8}$$

Note that μ_j, $j = 1, 2, \dots, n$, may be complex.

Remark 4.2. **(i)** If $\Phi(0) = I$, then from item (b) of Theorem 4.3.1 it follows that

$$\det\big(B\big) = \prod_{j=1}^{n} \rho_j = e^{\int_0^T \operatorname{tr}\left(A(s)\right)ds}.$$

(ii) Since the trace is the sum of the eigenvalues, we also have

$$\operatorname{tr}(B) = \sum_{j=1}^{n} \rho_j.$$

(iii) The exponential exponents are not unique since if $\rho_j = e^{\mu_j T}$, then $\rho_j = e^{(\mu_j + \frac{2\pi i}{T})T}$.

(iv) The Floquet multipliers ρ_j are intrinsic parameters of system (4.3.1) and do not depend on the choice of the fundamental matrix $\Phi(t)$.

Proof (of (iv)*).* Suppose $\Psi(t)$ is another fundamental matrix. Then by Theorem 4.3.1, there is a nonsingular matrix B such that

$$\Psi(t+T) = \Psi(t)B.$$

Now by Theorem 3.2.5

$$\Psi(t) = \Phi(t)C,$$

where C is a nonsingular matrix. Thus

$$\Psi(t+T) = \Phi(t+T)C$$

or

$$\Psi(t)B = (\Phi(t)B)C.$$

This gives

$$\Phi(t)CB = \Phi(t)BC, \quad \text{or} \quad CB = BC.$$

As a consequence,

$$CBC^{-1} = B,$$

so the eigenvalues of B and C are the same. ☐

Copyright Elsevier 2022

Theorem 4.3.2. *Let ρ be the Floquet multiplier of* (4.3.1) *with the corresponding Floquet exponent μ. Then there exists a solution $x(t)$ of* (4.3.1) *such that*

- **(a)** $x(t+T)=\rho x(t)$;
- **(b)** *There exists a continuously differentiable periodic $n \times 1$ vector function p with period T such that $x(t)=e^{\mu t}p(t)$.*

Proof. Let ρ be an eigenvalue of the matrix B with corresponding eigenvector b. Let $\Phi(t)$ be a fundamental matrix of the Floquet system (4.3.1) such that $x(t)=\Phi(t)b$. Then

$$\begin{aligned} x(t+T) &= \Phi(t+T)b \\ &= \Phi(t)Bb \\ &= \rho\Phi(t)b \\ &= \rho x(t). \end{aligned}$$

This proves (a). As for (b), we take $p(t)=x(t)e^{-\mu t}$. Then

$$\begin{aligned} p(t+T) &= x(t+T)e^{-\mu(t+T)} \\ &= \rho x(t)e^{-\mu(t+T)} \\ &= \rho e^{-\mu T}x(t)e^{-\mu t} \\ &= x(t)e^{-\mu t} \\ &= p(t), \end{aligned}$$

where we have used $\rho=e^{\mu T}$. This shows that $p(t)$ is periodic with period T. As a result, we have that $x(t)=e^{\mu t}p(t)$. This completes the proof of (b) and the theorem. ☐

Remark 4.3. Suppose a Floquet multiplier ρ is complex. Since ρ is an eigenvalue of the matrix B, then so is its conjugate $\bar{\rho}$. Then we have two solutions, x and $\bar{x}$. Let the Floquet exponent $\mu=\zeta+i\eta$, and consider the periodic complex vector $p(t)=q(t)+ir(t)$. We may write the corresponding two solutions as

$$x(t)=e^{\mu t}p(t) \ \text{ and } \ x(t)=e^{\bar{\mu}t}\bar{p}(t).$$

Explicitly, we have

$$\begin{aligned} x(t) &= e^{(\zeta+i\eta)t}(q(t)+ir(t)) \\ &= e^{\zeta t}\Big[\big(q(t)\cos(\eta t)-r(t)\sin(\eta t)\big)+i\big(r(t)\cos(\eta t)+q(t)\sin(\eta t)\big)\Big] \end{aligned}$$

and

$$\begin{aligned} \bar{x}(t) &= e^{(\zeta-i\eta)t}(q(t)-ir(t)) \\ &= e^{\zeta t}\Big[\big(q(t)\cos(\eta t)-r(t)\sin(\eta t)\big)-i\big(r(t)\cos(\eta t)+q(t)\sin(\eta t)\big)\Big]. \end{aligned}$$

Copyright Elsevier 2022

As a consequence, we may write the linearly independent real solutions

$$x_R = \mathrm{Re}\Big[e^{\mu t} p(t)\Big] = e^{\zeta t}\Big[q(t)\cos(\eta t) - r(t)\sin(\eta t)\Big], \tag{4.3.9}$$

$$x_I = \mathrm{Im}\Big[e^{\mu t} p(t)\Big] = e^{\zeta t}\Big[q(t)\sin(\eta t) + r(t)\cos(\eta t)\Big]. \tag{4.3.10}$$

Lemma 4.1. *(Logarithmic matrix) If B is an $n \times n$ matrix, then there exists an $n \times n$ (complex) matrix C such that $B = e^C$.*

Proof. Let λ_j, $j = 1, 2, \ldots, m$, with $m \le n$ denote the eigenvalues of B. We already know that

$$e^{P^{-1}CP} = P^{-1}e^C P.$$

Therefore we may assume that P is in Jordan canonical form, that is,

$$P = diag\big(J_1, J_2, \ldots, J_n\big)$$

with

$$J_j = \lambda_j + N_j,\ \lambda_j \neq 0,$$

where J_j and N_j are defined in Theorem 3.2.12. Suppose that

$$B = diag\big(B_1, B_2, \ldots, B_n\big),$$

where

$$B_j = \begin{pmatrix} \lambda_j & 1 & & \\ & \lambda_j & \ddots & \\ & & & 1 \\ & & & \lambda_j \end{pmatrix},\ j = 1, 2, \ldots m.$$

Let $l_j \times l_j$ be the size of $B_j = \lambda_j I_j + N_j$, where $N^{l_j} = 0$ (zero matrix) for all $k \ge m$. Thus $\sum_{k=1}^{m} l_k = n$, and so we have constructed a matrix B of size $n \times n$. Thus if we can prove that for every B_j, there exists a matrix C_j such that $B_j = e^{C_j}$, then $B = e^C$. Define

$$C_j := (\mathrm{Ln}(\Lambda_j) I_j + L_j,$$

where

$$L_j := -\sum_{k=1}^{m} \frac{(-N_j)^k}{k\lambda_j^k} \equiv \mathrm{Ln}(I_j + \frac{N_j}{\lambda_j}).$$

Recall that at $x = 0$,

$$\mathrm{Ln}(1 + x) = \sum_{k=1}^{\infty} \frac{(-x)^k}{k},\ \ |x| < 1,$$

Copyright Elsevier 2022

which implies that

$$1 + x = e^{\mathrm{Ln}(1+x)} = 1 + (x - x^2/2 + x^3/3 + \dots) + \frac{1}{2!}(x - x^2/2 \\ + x^3/3 + \dots)^2 + \frac{1}{3!}(x - x^2/2 + x^3/3 + \dots)^3 + \dots.$$

Since $N^{l_j} = 0$ (zero matrix) for all $k \geq m$, we must have

$$e^{L_j} = I_j + \frac{N_j}{\lambda_j}$$

or

$$B_j = e^{\mathrm{Ln}(\lambda_j) I_j + L_j},$$

where we have loosely used the fact that $B_j = e^{\mathrm{Ln}(B_j)}$. This completes the proof. □

Now we are ready to state and prove the Floquet theorem.

Theorem 4.3.3. *(Floquet theorem) Every fundamental matrix of* (4.3.1) *has the form*

$$\Phi(t) = P(t)e^{Ct},$$

where $P(t)$ is a T-periodic matrix, and C is a constant $n \times n$ matrix.

Proof. Let $\Phi(t)$ be a fundamental matrix of (4.3.1). Then

$$\begin{aligned}(\Phi^{-1}(t)\Phi(t+T))' &= (\Phi^{-1}(t))'\Phi(t+T) + \Phi^{-1}(t)\Phi'(t+T) \\ &= -\Phi^{-1}(t)A(t)\Phi(t+T) + \Phi^{-1}(t)A(t)\Phi(t+T) \\ &= 0.\end{aligned}$$

Thus

$$\Phi^{-1}(t)\Phi(t+T) = B \;\; \text{(constant matrix)},$$

or

$$\Phi(t+T) = \Phi(t)B.$$

Since $\Phi^{-1}(t)$ and $\Phi(t+T)$ are nonsingular, B is also nonsingular. Thus by Lemma 4.1 $B = e^{CT}$ for some constant matrix C. Left to show that $P(t)$ is periodic with period T. We define $P(t) = \Phi(t)e^{-Ct}$. Then

$$\begin{aligned}P(t+T) &= \Phi(t+T)e^{-C(t+T)} \\ &= \Phi(t)e^{CT}e^{-C(t+T)} \\ &= \Phi(t)e^{-Ct} \\ &= P(t).\end{aligned}$$

This completes the proof. □

Copyright Elsevier 2022

Example 4.8. Let us find the Floquet multipliers and exponents of

$$x'(t) = \begin{pmatrix} -1 & 1 \\ 0 & 1+\cos(t) - \frac{\sin(t)}{2+\cos(t)} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

We notice that the corresponding coefficient matrix is periodic with period 2π. We easily solve

$$x_2' = \left(1 + \cos(t) - \frac{\sin(t)}{2+\cos(t)}\right) x_2$$

using separation of variables and obtain

$$x_2 = c_2 e^{t+\sin(t)}(2+\cos(t)).$$

Substituting x_2 into $x_1' = -x_1 + x_2$ and then using the variation of parameters formula, we obtain

$$x_1 = c_2 e^{t+\sin(t)} + c_1 e^{-t}.$$

Setting $c_1 = c_2 = 1$, we obtain the fundamental matrix

$$\Phi(t) = \begin{pmatrix} e^{t+\sin(t)} & e^{-t} \\ e^{t+\sin(t)}(2+\cos(t)) & 0 \end{pmatrix}.$$

From Definition 4.3.1, we have

$$B := \Phi^{-1}(0)\Phi(T) = \Phi^{-1}(0)\Phi(2\pi) = \begin{pmatrix} 0 & \frac{1}{3} \\ 1 & -\frac{1}{3} \end{pmatrix} \begin{pmatrix} e^{2\pi} & e^{-2\pi} \\ 3e^{2\pi} & 0 \end{pmatrix} = \begin{pmatrix} e^{2\pi} & 0 \\ 0 & e^{-2\pi} \end{pmatrix}.$$

Then the eigenvalues of B, $\rho_1 = e^{2\pi}$ and $\rho_2 = e^{-2\pi}$ are the Floquet multipliers with Floquet exponents $\mu_1 = 2\pi$ and $\mu_2 = -2\pi$.

Example 4.9. Find the Floquet multiplier and exponent of

$$x'(t) = (2 - \cos(t))x(t).$$

Using separation of variables, we find the solution

$$x(t) = Ke^{2t - \sin(t)}$$

for some constant K. Set $K = 1$. Then the Floquet multiplier is $\rho = x^{-1}(0)x(2\pi) = 1e^{4\pi}$, and the Floquet exponent is $\mu = 4\pi$.

One of the main purposes of Floquet theory is to study the stability of the zero solution of (4.3.1). It is evident from Theorem 4.3.2 that the behavior of a solution depends on the Floquet exponent μ. In fact, from Theorem 4.3.2 we have that

$$x(t) = e^{\mu t} p(t),$$

Copyright Elsevier 2022

where $p(t)$ is a periodic $n \times 1$ vector. Let x_j be the jth component of the vector solution. Then from Theorem 4.3.2 we have that

$$x_j(t) = \rho_j x_j(t)$$

and

$$x_j(t + NT) = \rho_j^N x_j(t) \to 0 \text{ as } N \to \infty.$$

Now we can easily see that each Floquet multiplier falls into one of the following categories:

(a) If $|\rho| < 1$, then $\mathrm{Re}(\mu) < 0$ and so $x(t) \to 0$ as $t \to \infty$;
(b) If $\rho = \pm 1$, then $\mathrm{Re}(\mu) = 0$, and so the solution is periodic with period T;
(c) If $|\rho| > 1$, then $\mathrm{Re}(\mu) > 0$, and so $x(t) \to \infty$ as $t \to \infty$.

We have the following general theorem concerning the stability of the zero solution of (4.3.1).

Theorem 4.3.4. *The zero solution of* (4.3.1) *is*

(i) *stable if and only if the Floquet multipliers ρ satisfy $|\rho| \leq 1$ and there is a complete set of eigenvectors for any multiplier of modulus 1;*
(ii) *asymptotically stable if and only if $|\rho| < 1$ for every ρ.*

Proof. Let $\Phi(t)$ be the fundamental matrix of (4.3.1). Then by the Floquet theorem, we have that $\Phi(t) = P(t)e^{Ct}$. Then the solutions of (4.3.1) are given by $x(t) = P(t)e^{Ct}x_0$, where $x_0 \in \mathbb{R}^n$. We make two claims:
(1) the stability of the zero solution of (4.3.1) is the same as for

$$y'(t) = Cy(t), \tag{4.3.11}$$

which has solutions of the form $y(t) = e^{Ct}x_0$. To see this, let M be a positive constant. Since $P(t)$ is continuous and periodic, we have that $||P(t)|| \leq M$ for all $t \in \mathbb{R}$. Thus $|x(t)| = |P(t)e^{Ct}x_0| \leq M||e^{Ct}x_0|| = M|y(t)|$, and this completes the proof of the first claim.
(2) $y(t) = P^{-1}(t)x(t)$ is a solution of $y'(t) = Cy(t)$. To see this, let $y(t) = P^{-1}(t)x(t)$. Then

$$\begin{aligned} y(t) &= P^{-1}(t)\Phi(t)x_0 \\ &= P^{-1}(t)P(t)e^{Ct}x_0 \\ &= e^{Ct}x_0, \end{aligned}$$

which is a solution of $y'(t) = Cy(t)$. This completes the proof of the second claim.

Next, we address the proof of stability.

If $|\rho| < 1$ for all Floquet multipliers, then $\mathrm{Re}(\mu) < 0$ for all Floquet exponents, and the zero solution is AS for (4.3.11) and hence for (4.3.1).

Copyright Elsevier 2022

Now we assume that $|\rho| \le 1$ for all ρ and there are no generalized eigenvectors (see (3.2.26)) of e^{CT} corresponding to Floquet multipliers with $|\rho| = 1$. Then $\mathrm{Re}(\mu) \le 0$ for all eigenvalues of C, and there are no generalized eigenvectors of C corresponding to eigenvalues with $\mathrm{Re}(\mu) = 0$. As a consequence, we have that $|e^{Ct}|$ is uniformly bounded. Thus the zero solution is stable for (4.3.11) and hence for (4.3.1).

If $\rho > 1$ for some ρ or if there is a generalized eigenvector of e^{CT} with $\rho = 1$, then either C has an eigenvalue with $\mathrm{Re}(\mu) > 1$ or C has a generalized eigenvector with $\mathrm{Re}(\mu) = 0$. In both cases, $|y(t)| \to \infty$ as $t \to \infty$. This implies that the zero solution of (4.3.11) is unstable. On the other hand, since $P(t)$ is continuous and periodic, we have that $P^{-1}(t)$ is also continuous and periodic. Thus

$$y(NT) = P^{-1}(NT)x(NT)x_0$$

for a positive integer N. Therefore

$$\infty = \lim_{N\to\infty} |y(NT)| \le ||P^{-1}(NT)|| \lim_{N\to\infty} |x(NT)|,$$

and the zero solution is also unstable for (4.3.1). This completes the proof. □

We provide the following example.

Example 4.10. Consider the periodic system with period π

$$x'(t) = \begin{pmatrix} -1 + \frac{1}{2}\sin^2(t) & -1 - \frac{1}{2}\cos(t)\sin(t) \\ 1 - \frac{1}{2}\cos(t)\sin(t) & -1 + \frac{1}{2}\cos^2(t) \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

By inspection we found the fundamental matrix to be

$$\Phi(t) = \begin{pmatrix} -e^{-t/2}\sin(t) & e^{-t}\cos(t) \\ e^{-t/2}\cos(t) & e^{-t}\sin(t) \end{pmatrix}.$$

We encourage the reader to verify that

$$\Phi'(t) = A(t)\Phi(t).$$

Then

$$\begin{aligned} B &:= \Phi^{-1}(0)\Phi(T) = \Phi^{-1}(0)\Phi(\pi) \\ &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & -e^{-\pi} \\ -e^{-\pi/2} & 0 \end{pmatrix} = \begin{pmatrix} -e^{-\pi/2} & 0 \\ 0 & -e^{-\pi} \end{pmatrix}, \end{aligned}$$

and thus the eigenvalues of B are given by $\rho_1 = -e^{-\pi/2}$ and $\rho_2 = -e^{-\pi}$ with $|\rho_i| < 1, i = 1, 2$. By Theorem 4.3.4 the origin $(0, 0)$ is asymptotically stable.

Copyright Elsevier 2022

4.3.1 Mathieu's equation

We begin by considering the 2×2 real entries and constant matrix

$$D = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Let $L(\lambda) = \det(D - \lambda I)$. Then $L(\lambda)$ can be easily computed to be

$$L(\lambda) = \lambda^2 - (a+d)\lambda + ad - bc = \lambda^2 - \operatorname{tr}(D)\lambda + \det(D). \tag{4.3.12}$$

On the other hand, if λ_1 and λ_2 are the eigenvalues of D, not necessarily distinct, then

$$L(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) = \lambda^2 - (\lambda_1 + \lambda_2)\lambda + \lambda_1\lambda_2. \tag{4.3.13}$$

A quick comparison of (4.3.12) with (4.3.13) gives

$$\operatorname{tr}(D) = \lambda_1 + \lambda_2 \tag{4.3.14}$$

and

$$\det(D) = \lambda_1\lambda_2. \tag{4.3.15}$$

Next, we consider Mathieu's equation

$$x''(t) + \big(\alpha + \beta\cos(t)\big)x(t) = 0 \tag{4.3.16}$$

with parameters α and β. Eq. (4.3.16) was discovered by Émile Léonard Mathieu, who encountered it while studying vibrating elliptical drumheads. It has applications in many fields of the physical sciences, such as optics, quantum mechanics, and general relativity. The equation tends to occur in problems involving periodic motion or in the analysis of partial differential equations and boundary value problems possessing elliptic symmetry. Using the transformation $x_1 = x$, $x_2 = x'$, we write (4.3.16) in the system form

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -\alpha - \beta\cos(t) & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

It is clear that the system is a Floquet system with a period of 2π. Let $\Phi(t)$ be a fundamental matrix. Then the Floquet multipliers ρ_1 and ρ_2 are the eigenvalues of the matrix

$$B = \Phi^{-1}(0)\Phi(T).$$

Since $\operatorname{tr}(A) = 0$, where

$$A(t) = \begin{pmatrix} 0 & 1 \\ -\alpha - \beta\cos(t) & 0 \end{pmatrix},$$

Copyright Elsevier 2022

by Theorem 4.3.1, we have that

$$\det\big(B\big) = \prod_{j=1}^{n} \rho_j = e^{\int_0^T \operatorname{tr}\big(A(s)\big)ds} = e^0 = 1.$$

Thus by (4.3.15),

$$\rho_1\rho_2 = 1.$$

As consequence of (4.3.12)–(4.3.15), the eigenvalues or Floquet multipliers must satisfy the quadratic equation $\rho^2 - (\rho_1 + \rho_2)\rho + 1 = 0$. Letting $\phi := \phi(\alpha, \beta) = \rho_1 + \rho_2$, we arrive at the characteristic equation

$$\rho^2 - \phi\rho + 1 = 0. \tag{4.3.17}$$

Eq. (4.3.17) has the roots

$$\rho_{1,2} = \frac{1}{2}\big(\phi \pm \sqrt{\phi^2 - 4}\big).$$

Despite the fact that we cannot solve for ϕ, we can still deduce some information about the solutions by considering particular values for ϕ. Below we consider several cases that depend on assigned values of ϕ.

1. Case 1: $\phi > 2$.
   Since $\rho_{1,2} = \frac{1}{2}\big(\phi \pm \sqrt{\phi^2 - 4}\big)$, we have $\rho_1 > 1$, and since $\rho_1\rho_2 = 1$, we have $\rho_1 > 1 > \rho_2 > 0$. As $\rho_2 = \frac{1}{\rho_1}$, we conclude that $\mu_2 = -\mu_1$. Thus according to Theorem 4.3.2, the solution must be of the form

   $$x(t) = c_1 e^{\mu_1 t} p_1(t) + c_2 e^{-\mu_1 t} p_2(t),$$

   where $p_1(t)$ and $p_2(t)$ are both periodic with period 2π. Moreover, the zero solution is unstable, and solutions are unbounded.
2. Case 2: $\phi = 2$.
   Then $\rho_1 = \rho_2 = 1$. In this case, Theorem 4.3.2 guarantees one solution of the form $e^{\mu t}p(t)$. On the other hand, if B has two corresponding linearly independent eigenvectors, then we can find two linearly independent 2π-periodic functions $p_1(t)$ and $p_2(t)$, so that the general solution has the form $x(t) = c_1 p_1(t) + c_2 p_2(t)$, since $\rho = 1$ implies $\mu = 0$. Now if B has only one eigenvector, then we end up with a solution of the form $p_1(t)$ and another of the form $tp_1(t) + p_2(t)$. This is due to the fact that the Jordan canonical form of the matrix B is $\begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix}$, and the solution takes the form

   $$\Phi(t) = P(t)e^{\begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix} t} = P(t)\begin{pmatrix} e^{\lambda t} & te^{\lambda t} \\ 0 & e^{\lambda t} \end{pmatrix} = \begin{pmatrix} p_1(t) \\ p_2(t) \end{pmatrix}\begin{pmatrix} e^{\lambda t} & te^{\lambda t} \\ 0 & e^{\lambda t} \end{pmatrix}.$$

Copyright Elsevier 2022

In conclusion, we have a solution of the form

$$x(t) = (c_1 + c_2 t) p_1(t) + c_2 p_2(t),$$

which is unbounded, and, moreover, the zero solution is unstable.

3. Case 3: $\phi = -2$.
Then $\rho_1 = \rho_2 = -1$. This is similar to Case 3. We know that $\rho = e^{\mu T} = -1$, which implies that $\mu = \frac{i\pi}{T}$, since

$$e^{\mu T} = e^{\frac{i\pi}{T} T} = e^{i\pi} = -1.$$

The solution is given by

$$x(t) = (c_1 + c_2 t) p_1(t) e^{\frac{i\pi}{T} t} + c_2 p_2(t) e^{\frac{i\pi}{T} t},$$

which is a combination of a periodic solution with period 4π and a nonperiodic solution. Again, solutions are unbounded, and the zero solution is unstable.

4. Case 4: $-2 < \phi < 2$.
Without loss of generality, we may define η by $\phi = 2\cos(\eta T)$, where $0 < \eta T < \pi$, so that

$$\begin{aligned}\rho &= \frac{1}{2}\left(\phi \pm \sqrt{\phi^2 - 4}\right)\\ &= \cos(\eta T) \pm i\ \sin(\eta T)\\ &= e^{\pm i\eta T}.\end{aligned}$$

Since $\zeta = 0$, Eqs. (4.3.9) and (4.3.10) reduce to

$$\begin{aligned}x_R &= \mathrm{Re}\left[e^{i\eta t} p(t)\right] = q(t)\cos(\eta t) - r(t)\sin(\eta t),\\ x_I &= \mathrm{Im}\left[e^{i\eta t} p(t)\right] = q(t)\sin(\eta t) + r(t)\cos(\eta t),\end{aligned}$$

where $p(t) = q(t) + i\ r(t)$ is periodic with period 2π. With this in mind, the solution takes the form

$$x(t) = c_1\Big(q(t)\cos(\eta t) - r(t)\sin(\eta t)\Big) + c_2\Big(q(t)\sin(\eta t) + r(t)\cos(\eta t)\Big).$$

We easily see that the zero solution is stable and solutions are bounded, but it is not periodic in general as there are two frequencies 2π and η. In such a case, the solution is said to be pseudoperiodic. Next, we examine the period of η. Now $e^{i\eta t}$ has the period $\bar{T} := \frac{2\pi}{\eta}$. Since $0 < 2\cos(\eta T) < \pi$, or, $\phi \neq \pm 2$, we must have $\eta T \neq j\pi$, $j = 1, 2, \dots$, or $\dfrac{2\pi T}{\bar{T}} \neq j\pi$, which implies that $\dfrac{2T}{j} \neq \bar{T}$. This gives $\bar{T} \neq 2T, T, \dfrac{2}{3}T, \dots.$

Copyright Elsevier 2022

Note that in order that $\bar{T} = nT$, we must have

$$\eta = \frac{2\pi}{nT}$$

for $n \neq 1, 2$.

4.3.2 Applications to Mathieu's equation

4.3.2.1 Inverted pendulum

An application of Mathieu's equation is the inverted pendulum depicted in Fig. 4.3. We assume that the pendulum is frictionless and has a massless rod of length l. If F_{pivot} is the force acting on the pivot, τ_{net} is the net force to external torque, and I is the moment of inertia, then by Newton's second law, we have

$$F_{\text{pivot}} = ma = m\frac{d^2y}{dt^2}, \tag{4.3.18}$$

$$\tau_{\text{net}} = I\frac{d^2\theta}{dt^2} = ml^2\frac{d^2\theta}{dt^2}. \tag{4.3.19}$$

If F is the force acting on the particle and τ is the torque, then

$$\tau = rF\sin(\theta),$$

where r is the distance from the axis of rotation to the particle. So the gravitational torque is

$$\tau_{\text{grav}} = rF_{\text{grav}}\sin(\theta) = mgl\sin(\theta).$$

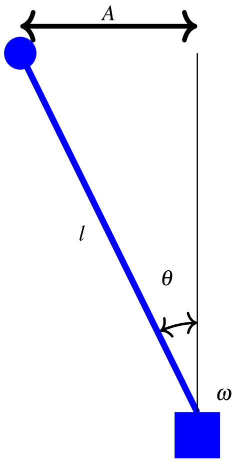

FIGURE 4.3

Inverted pendulum plotted in xy-coordinates.

Copyright Elsevier 2022

Since the harmonic motion of the pendulum can be expressed as $y(t) = A\cos(\omega t)$, Eq. (4.3.18) becomes

$$F_{\text{pivot}} = ma = m\omega^2 A\cos(\omega t).$$

Now the torque exerted by the pivot, τ_{pivot} is given by

$$\tau_{\text{pivot}} = r F_{\text{pivot}}\ \sin(\theta) = -ml\omega^2 A\cos(\omega t)\sin(\theta).$$

Thus the total torque $\tau_{\text{net}} = \tau_{\text{grav}} + \tau_{\text{pivot}}$. As a result, expression (4.3.19) yields the expression

$$ml^2\frac{d^2\theta}{dt^2} = mgl\sin(\theta) - ml\omega^2 A\cos(\omega t)\sin(\theta)$$

or

$$\frac{d^2\theta}{dt^2} + \big(\frac{g}{l} - \frac{\omega^2 A}{l}\cos(t)\big)\sin(\theta),$$

setting $\sin(\theta) \approx \theta$ for small oscillations, the above expression reduces to

$$\theta'' + \big(\alpha + \beta\cos(t)\big) = 0$$

with $\alpha = \dfrac{g}{l}$, $\beta = -\dfrac{\omega^2 A}{l}$, and period $T = 2\pi$.

4.4 Exercises

Exercise 4.1. Discuss the flow of solutions around the equilibrium solutions as we did in Fig. 4.1 for the following systems:

(a)

$$x'(t) = (1 - x^2)xe^x,\ \ x(0) = x_0 \neq 0;$$

(b)

$$x'(t) = x^3 + x^2 + 6x,\ \ x(0) = x_0 \neq 0.$$

Exercise 4.2. Discuss the stability as we did in Example 4.2 for the following IVPs:

(a)

$$(t^2 + 9)x'(t) + tx = 0,\ \ x(0) = x_0 \neq 0;$$

(b)

$$(1 + t)x'(t) = -x,\ x(t_0) = x_0,\ \ t \geq t_0 > -1.$$

Copyright Elsevier 2022

Exercise 4.3. Show that the zero solution of

$$x'(t) = -x^3, \;\; x(t_0) = x_0 \neq 0,$$

is UAS.

Exercise 4.4. The solution of

$$x'(t) = a(t)x(t), \; x(t_0) = x_0 \neq 0, \; t \geq t_0 \geq 0, \tag{4.4.1}$$

is given by

$$x(t) = x_0 e^{\int_{t_0}^{t} a(s)ds},$$

where $a(t)$ is continuous for $t \geq 0$. Show that the zero solution of (4.4.1) is

(a) stable if and only if there exists a positive constant M such that

$$e^{\int_{t_0}^{t} a(s)ds} < M, \;\; t \geq 0;$$

(b) asymptotically stable if and only if

$$\int_0^t a(s)ds \to -\infty \;\text{ as }\; t \to \infty;$$

(c) uniformly stable if and only if there exists a positive constant M such that $\displaystyle\int_{t_1}^{t_2} a(s)ds \leq M$ for all $0 < t_1 < t_2 < \infty$;

(d) uniformly asymptotically stable if and only if there exist positive constants M and α such that $\displaystyle\int_{t_0}^{t} a(s)ds \leq -\alpha(t - t_0) + M$.

Exercise 4.5. Find the fundamental matrix and study the stability of the zero solution of the given system for $t > 0$:

(a)

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -\frac{1}{2t^2} & -\frac{5}{2t} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix},$$

(b)

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -\frac{8}{t^2} & -\frac{10}{t} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Exercise 4.6. Find the Floquet multipliers and exponents of

$$x'(t) = \begin{pmatrix} \frac{\cos(t)+\sin(t)}{2+\sin(t)-\cos(t)} & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Copyright Elsevier 2022

Exercise 4.7. Find the Floquet multipliers and exponents of

$$x'(t) = \begin{pmatrix} 1 + \frac{\cos(t)}{2+\sin(t)} & 0 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Exercise 4.8. Find the Floquet multipliers and exponents of

(a)

$$x'(t) = \cos(3t)x(t);$$

(b)

$$x'(t) = \Big(\sin(3t) + \cos(3t)\Big)x(t);$$

(c)

$$x'(t) = \Big(-1 + \cos(2t)\Big)x(t).$$

Exercise 4.9. Prove that $B_j = e^{\mathrm{Ln}(B_j)}$ in the proof of Lemma 4.1.

Exercise 4.10. Carry out a similar discussion as in Section 4.3.1 for the second-order Hill equation

$$x''(t) + a(t)x(t) = 0,$$

where the function a is continuous and periodic with period T.

Exercise 4.11. Find the logarithm of the rotation matrix

$$A = \begin{pmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{pmatrix}.$$

Exercise 4.12. Show that all solutions of (4.2.1) are bounded if and only if its zero solution is stable.

Copyright Elsevier 2022

CHAPTER

5

Qualitative analysis of linear systems

This chapter is exclusively devoted to the study of the stability of linear systems, near-linear systems, perturbed systems, and autonomous systems in the plane.

5.1 Preliminary theorems

In Section 4.2 of Chapter 4, we discussed the stability, uniform stability, asymptotic stability, and uniform asymptotic stability of the zero solution of the non-autonomous linear system

$$x' = A(t)x$$

by imposing conditions on its fundamental and principal matrices. In this section, we give explicit criteria that satisfy the conditions that were imposed only for the linear system with constant coefficients

$$x' = Ax, \tag{5.1.1}$$

where A is an $n \times n$ matrix with constant entries. We begin with the following lemma.

Lemma 5.1. *Let*

$$r(t) = t^m e^{-\alpha t}, \ t \geq 0,$$

where m is a non-negative integer, and α is a positive constant. Then there exists a positive constant D depending on m and α such that $r(t) \leq D$.

Proof. If $m = 0$ then $r(t) \leq 1 := D$. On the other hand, if $m > 0$, then by repeated application of L'Hôpital's rule we have $\lim_{t\to\infty} t^m e^{-\alpha t} = 0$. Moreover, since $r(0) = 0$, $r(t)$ is continuous, and $r(t) \geq 0$, we have that $r(t) \leq D$ for some positive constant D. This completes the proof. □

Definition 5.1.1. Let A be a square matrix. We define the *spectrum* of A as

$$\sigma(A) = \{\lambda : \det(A - \lambda I) = 0\}.$$

Thus the inequality

$$Re\big(\sigma(A)\big) < \zeta$$

for some real number ζ means that all the eigenvalues of A have real parts less than ζ.

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00011-5
Copyright © 2023 Elsevier Inc. All rights reserved.

Copyright Elsevier 2022

The next theorem is concerned with eigenvalues of multiplicity m.

Theorem 5.1.1. *Let* λ *be an eigenvalue of a matrix* A *with* $Re\big(\sigma(A)\big) < \zeta$. *Then for any integer* $m \geq 0$, *there exists a positive constant* D *such that*

$$t^m e^{\lambda t} \leq D e^{\zeta t} \text{ for all } t \geq 0.$$

Proof. Let $\lambda = \alpha + i\beta$ with $\alpha, \beta \in \mathbb{R}$. If $\beta = 0$, that is, λ is real, then since $Re\big(\sigma(A)\big) < \zeta$, we have that $\alpha - \zeta < 0$. So by Lemma 5.1

$$t^m e^{(\alpha-\zeta)t} \leq D \text{ for all } t \geq 0.$$

Multiplying this inequality by $e^{\zeta t}$, we obtain

$$t^m e^{\lambda t} = t^m e^{\alpha t} \leq D e^{\zeta t} \text{ for all } t \geq 0.$$

Now if $\beta \neq 0$, that is, λ is complex, then

$$|t^m e^{\lambda t}| = |t^m e^{(\alpha+i\beta)t}| = t^m e^{\alpha t} \leq D e^{\zeta t} \text{ for all } t \geq 0,$$

since $\alpha = Re\big(\sigma(A)\big) < \zeta$. This completes the proof. □

Theorem 5.1.2. *Let* λ *be an eigenvalue of a matrix* A *with* $Re\big(\sigma(A)\big) < \zeta$. *Then for some positive constant* D, *any solution* x *of* (5.1.1) *satisfies*

$$|x(t)| \leq D e^{\zeta t} \text{ for all } t \geq 0.$$

Proof. Let $\lambda_1, \lambda_2, \ldots, \lambda_k$ be eigenvalues of A. We can form a set of fundamental solution, $x_1, x_2, \ldots, x_n$ and find an integer $N \geq 0$ such that each solution is of the form $x_j = t^m e^{\lambda_N t}$, $N = 1, 2, \ldots, k$, for integer m. Then by Theorem 5.1.1, we have that $|x_j(t)| \leq V_j e^{\zeta t}$ for positive constants V_j. If x is an arbitrary solution of (5.1.1), then it can be written in the form

$$x(t) = c_1 x_1(t) + c_2 x_2(t) + \ldots + c_n x_n(t).$$

Then for $t \geq 0$,

$$\begin{aligned}
|x(t)| &\leq |c_1||x_1(t)| + |c_2||x_2(t)| + \ldots + |c_n||x_n(t)| \\
&\leq |c_1| V_1 e^{\zeta t} + |c_2| V_2 e^{\zeta t} + \ldots + |c_n| V_n e^{\zeta t} \\
&= \Big(|c_1| V_1 + |c_2| V_2 + \ldots + |c_n| V_n\Big) e^{\zeta t}.
\end{aligned}$$

This completes the proof. □

The next theorem plays an important role in the study of stability, and its proof depends on the Putzer algorithm, Theorem 3.2.14.

Copyright Elsevier 2022

Theorem 5.1.3. *Let λ_i, $i = 1, 2, \ldots, k$, be the distinct eigenvalues of A, where λ_i has multiplicity n_i, and $n_1 + n_2 + \ldots + n_k = n$. If $Re\big(\sigma(A)\big) < \zeta$, then there is a positive constant D such that*

$$e^{At} \leq De^{\zeta t} \text{ for all } t \geq 0.$$

Proof. From Theorem 3.2.14 we know that

$$e^{At} = \sum_{j=0}^{n-1} \mu_{j+1}(t) P_j, \tag{5.1.2}$$

where $\mu_1(t), \mu_2(t), \ldots, \mu_n(t)$ satisfy the corresponding initial value problems

$$\mu_1' = \lambda_1 \mu_1,\ \mu_1(0) = 1;\ \mu_j' = \lambda_j \mu_j + \mu_{j-1}(t),\ \mu_j(0) = 0,\ j = 2, 3, \ldots, n,$$

and the matrices $P_0, P_1, \ldots, P_n$ are given by

$$P_0 = I,\quad P_j = \prod_{k=1}^{j} (A - \lambda_j I),\ j = 1, 2, \ldots, n.$$

Then we may easily verify that

$$\mu_1(t) = e^{\lambda_1 t},\ \ \mu_{j+1}(t) = e^{\lambda_{j+1} t} \int_0^t e^{-\lambda_{j+1} t} \mu_j(s) ds$$

for $j = 1, 2, \ldots, n-1$. Without loss of generality, we may choose the order in $\{\lambda_j\}$ so that the real parts do not decrease, that is, if $\lambda_j = \rho_j + i\sigma_j$, then $\rho_j \leq \rho_{j+1}$. We claim that

$$|\mu_j(t)| \leq \frac{t^{j-1}}{(j-1)!} e^{\rho_j t} \text{ for } t > 0,\ j = 1, 2, \ldots, n. \tag{5.1.3}$$

Obviously, (5.1.3) holds for $j = 1$, since $\mu_1(t) = e^{\lambda_1 t}$. Thus let it hold for j. Now from the above integral defining $\mu_{j+1}(t)$ we have

$$\mu_{j+1}(t) = e^{\rho_{j+1} t} \int_0^t e^{-\rho_{j+1} s} \frac{s^{j-1}}{(j-1)!} e^{\rho_j s} ds.$$

Since $e^{(\rho_j - \rho_{j+1})s} \leq 1$, the above integral reduces to

$$\mu_{j+1}(t) = e^{\rho_{j+1} t} \frac{1}{(j-1)!} \int_0^t s^{j-1} ds = \frac{t^j}{j!} e^{\rho_{j+1} t}.$$

By our setup, we have ρ^n is the largest of the real parts, and hence

$$\mu_{j+1}(t) \leq \frac{t^j}{j!} e^{\rho_n t}.$$

Copyright Elsevier 2022

For any exponent j and any $\rho^* > 0$, we have

$$t^j < he^{\rho^* t}$$

for all $t \geq 0$ and some positive constant h. Thus

$$\mu_{j+1}(t) \leq he^{(\rho^*+\rho_n)t}, \quad t \geq 0. \tag{5.1.4}$$

Now substitute (5.1.3) into (5.1.2) and then take the matrix norm to get

$$||e^{At}|| \leq \sum_{j=0}^{n-1} |\mu_{j+1}(t)|||P_j|| \leq \Big[h\sum_{j=0}^{n-1} ||P_j||\Big]e^{\zeta t} := De^{\zeta t}. \tag{5.1.5}$$

This completes the proof. □

As a direct consequence of Theorem 5.1.3, we have the following lemma.

Lemma 5.2. *Suppose all the eigenvalues of A have negative real parts. Then there are positive constants h, K, and ρ such that*

$$\mu_{j+1}(t) \leq he^{-\rho t} \ \text{ and } \ ||e^{At}|| \leq Ke^{-\rho t}, \ t \geq 0. \tag{5.1.6}$$

Theorem 5.1.4. **(i)** *Assume that every eigenvalue of the matrix A has a nonpositive real part and that the eigenvalues with zero real parts are simple. Then there is a positive constant D such that*

$$||e^{At}|| \leq D, \ t \geq 0.$$

Moreover, if x is a solution of (5.1.1), then it is bounded, and the zero solution is stable.

(ii) *If $Re(\sigma(A)) < 0$, then the zero solution is AS.*

(iii) *If there is an eigenvalue of A with positive real part, then the zero solution is unstable.*

Proof. If $\lambda = i\beta$ is a simple pure imaginary, then it contributes a bounded function of the form $e^{i\beta t}$ to a fundamental set of solutions. Thus we get a fundamental set of solutions with all elements bounded on $[0, \infty)$. Since e^{At} is formed from such a set, an argument similar to the proof of Theorem 5.1.3 shows that

$$||e^{At}|| \leq D$$

for some positive constant D. Now if x is a solution of (5.1.1) with $x(t_0) = x_0$, then

$$x(t) = e^{A(t-t_0)}x_0 \ \text{ for } \ t \geq t_0.$$

Let $\varepsilon > 0$ and set $\delta = \varepsilon/D$. Then for $|x_0| < \delta$, we have

$$|x(t)| = ||e^{A(t-t_0)}|||x_0| \leq D\delta = \varepsilon.$$

Copyright Elsevier 2022

This proves that the solution is bounded, and the zero solution is stable. The proof of (i) is complete.

As for (ii), the zero solution is stable by (i) since $Re(\sigma(A)) < 0$. Thus we may choose a real number $\zeta < 0$ such $Re(\sigma(A)) < \zeta$. By Theorem 5.1.3 there is a positive constant D such that $||e^{At}|| \leq De^{\zeta t}$ for all $t \geq 0$. Hence, for any initial condition $x(0) = x_0$, the solution x of (5.1.1) satisfies

$$|x(t, 0, x_0)| = |e^{At}x_0| \leq D|x_0|e^{\zeta t} \to 0 \text{ as } t \to \infty.$$

This completes the proof of (ii). ☐

Remark 5.1. Consider two matrices

$$A = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \text{ and } B = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

It is clear that each matrix has an eigenvalue 0 with multiplicity 2 (not simple). The zero solution of the corresponding system $x' = Ax$ is stable, whereas the zero solution of $x' = Bx$ is unstable. Therefore careful examination of the stability is required when dealing with eigenvalues with zero real parts of multiplicity higher than one.

Theorem 5.1.5. *If all the eigenvalues of A are distinct with $Re\big(\sigma(A)\big) < -\zeta$, where $\zeta > 0$, then the zero solution of* (5.1.1) *is UAS.*

Proof. By Lemma 5.2, we have that

$$||e^{At}|| \leq Ke^{-\zeta t}, \ t \geq 0,$$

and hence

$$||e^{A(t-s)}|| \leq Ke^{-\zeta(t-s)}, \ t \geq s \geq 0.$$

Now if x is a solution of (5.1.1) with $x(s) = x_0$, then

$$x(t) = e^{A(t-s)}x_0 \ \text{ for } \ t \geq s,$$

and the results follow from Theorem 4.2.3, since

$$e^{A(t-s)} = \Phi(t)\Phi^{-1}(s).$$

This completes the proof. ☐

5.2 Near-constant systems

In this section, we examine when solutions of a linear non-autonomous system behave like solutions of an autonomous linear system near zero. We have already seen that the stability of zero solution of the system

$$x'(t) = A(t)x(t)$$

Copyright Elsevier 2022

does not depend on the sign of the eigenvalues of the matrix $A(t)$. For example, the system

$$x'(t) = \begin{pmatrix} -1+\frac{3}{2}\cos^2(t) & 1-\frac{3}{2}\cos(t)\sin(t) \\ -1-\frac{3}{2}\cos(t)\sin(t) & -1+\frac{3}{2}\sin^2(t) \end{pmatrix} x(t) \tag{5.2.1}$$

has the eigenvalues

$$\lambda = \frac{-1 \pm i\sqrt{7}}{4}$$

and the principal matrix

$$\Psi(t) = \begin{pmatrix} e^{t/2}\cos(t) & e^{-t}\sin(t) \\ -e^{t/2}\sin(t) & e^{-t}\cos(t) \end{pmatrix}.$$

This tells us that solutions are unbounded and the zero solution is unstable. Thus the question that we wish to examine is that if, in some sense, the matrix $A(t)$ is close to a constant matrix A, then how closely do solutions of the non-autonomous system

$$x'(t) = A(t)x(t) \tag{5.2.2}$$

behave like solutions of the autonomous system

$$x'(t) = Ax(t)? \tag{5.2.3}$$

We assume that both matrices are $n \times n$ and $A(t)$ has continuous entries on some interval that includes the initial time t_0.

Theorem 5.2.1. *Assume that every eigenvalue of the matrix A has a nonpositive real part and that the eigenvalues with zero real parts are simple. If*

$$\int_0^\infty ||A(t) - A||dt \le E \tag{5.2.4}$$

for some positive constant E, then solutions of (5.2.2) *are bounded, and its zero solution is uniformly stable.*

Proof. By Theorem 5.1.4 there is a positive constant D such that

$$e^{At} \le D.$$

Rewrite (5.2.2) as

$$x'(t) = Ax(t) + \big(A(t) - A\big)x(t) \tag{5.2.5}$$

and set $g(t) = \big(A(t) - A\big)x(t)$. If x is a solution of (5.2.2) with $x(t_0) = x_0$, then it satisfies (5.2.5), and by the variation of parameters formula (3.3.6) we have that

$$x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^t e^{A(t-s)}\big(A(s) - A\big)x(s)ds. \tag{5.2.6}$$

Copyright Elsevier 2022

Taking the appropriate norms of both sides of (5.2.6) and estimating give, for $t \geq t_0 \geq 0$,

$$\begin{aligned} |x(t)| &= ||e^{A(t-t_0)}|||x_0| + \int_{t_0}^{t} ||e^{A(t-s)}||\,||A(s)-A||\,|x(s)|ds \\ &\leq D|x_0| + \int_{t_0}^{t} D||A(s)-A||\,|x(s)|ds \\ &\leq D|x_0|e^{\int_{t_0}^{t} D||A(s)-A||\,ds} \quad \text{(by Gronwall's inequality)} \qquad (5.2.7) \\ &\leq D|x_0|e^{DE}. \qquad (5.2.8) \end{aligned}$$

It follows that solutions are bounded and the zero solution is uniformly stable by choosing $\delta = \frac{\varepsilon}{De^{DE}}$ for any $\varepsilon > 0$ with $|x_0| < \delta$. □

Theorem 5.2.2. *Assume that all the eigenvalues of the matrix A of system (5.2.3) are distinct with negative real parts and there is a positive number (to be identified later in the proof) θ such that*

$$||A(t)-A|| < \theta \tag{5.2.9}$$

for all $t \geq t_0 \geq 0$. Then the zero solution of (5.2.2) is uniformly asymptotically stable.

Proof. Since $Re(\sigma(A)) < 0$, we may choose a real number $\zeta > 0$ such $Re(\sigma(A)) < -\zeta$. By Lemma 5.2, there is a positive constant K such that $||e^{At}|| \leq Ke^{-\zeta t}$ for all $t \geq 0$. If x is a solution of (5.2.2) with $x(t_0) = x_0$, then it satisfies (5.2.5), and by the variation of parameters formula (3.3.6), we have that

$$x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^{t} e^{A(t-s)}\big(A(s)-A\big)x(s)ds.$$

Let

$$0 < \theta < \frac{\zeta}{K}. \tag{5.2.10}$$

Taking the appropriate norms of both sides gives, for $t \geq 0$,

$$\begin{aligned} |x(t)| &= ||e^{A(t-t_0)}|||x_0| + \int_{t_0}^{t} ||e^{A(t-s)}||\,||A(s)-A||\,|x(s)|ds \\ &\leq Ke^{-\zeta(t-t_0)}|x_0| + \int_{t_0}^{t} Ke^{-\zeta(t-s)}\,\theta\,|x(s)|ds \end{aligned}$$

or

$$|x(t)|e^{\zeta(t-t_0)} \leq K|x_0| + \int_{t_0}^{t} Ke^{\zeta(s-t_0)}\,\theta\,|x(s)|ds.$$

Copyright Elsevier 2022

Let $z(t) = e^{\zeta(t-t_0)}|x(t)|$. Then the above inequality reduces to

$$z(t) \le K|x_0| + k\theta \int_{t_0}^{t} z(s)ds.$$

An application of Gronwall's inequality leads to

$$z(t) \le k|x_0|e^{k\theta(t-t_0)} \text{ for all } t \ge t_0 \ge 0,$$

and, consequently,

$$x(t)| \le k|x_0|e^{(k\theta-\zeta)(t-t_0)} \text{ for all } t \ge t_0 \ge 0,$$

from which we arrive at the uniform stability and uniform asymptotic stability of the zero solution by imitating the proof of Theorem 4.2.3. This completes the proof. ☐

Remark 5.2. There is no standard way for forming (5.2.5). It depends on what we want from the eigenvalues of A and conditions (5.2.4) and (5.2.9).

Example 5.1. We show that the zero solution of the non-autonomous system

$$x'(t) = \begin{pmatrix} \frac{e^{-t}}{3} & 1 - \frac{te^{-t}}{6} \\ -2 + \frac{1}{16(1+t)^2} & -3 + \frac{e^{-t}}{16} \end{pmatrix} x \tag{5.2.11}$$

is uniformly asymptotically stable. We write the system in the form

$$\begin{aligned} x'(t) &= \begin{pmatrix} 0 & 1 \\ -2 & -3 \end{pmatrix} x + \left[\begin{pmatrix} \frac{e^{-t}}{3} & 1 - \frac{te^{-t}}{6} \\ -2 + \frac{1}{16(1+t)^2} & -3 + \frac{e^{-t}}{16} \end{pmatrix} - \begin{pmatrix} 0 & 1 \\ -2 & -3 \end{pmatrix} \right] x \\ &= Ax + \big(A(t) - A\big)x. \end{aligned}$$

Now the eigenvalues of A are -2 and -1. We easily verify that

$$e^{A(t-t_0)} = \begin{pmatrix} e^{-(t-t_0)} & e^{-3(t-t_0)} \\ -e^{-(t-t_0)} & -3e^{-(t-t_0)} \end{pmatrix}, \ t \ge t_0 \ge 0,$$

and

$$||e^{A(t-t_0)}||_\infty \le 4e^{-(t-t_0)}, \ \ t \ge t_0 \ge 0.$$

Moreover,

$$||A(t) - A||_\infty = \max\{\frac{1}{3} + \frac{1}{6e}, \frac{1}{16} + \frac{1}{16}\} = \frac{1}{8} \text{ for all } t \ge t_0 \ge 0,$$

and condition (5.2.10) is satisfied with $K = 4$, $\zeta = 1$, and $\theta = 2$. Thus by Theorem 5.2.2 the zero solution of (5.2.11) is uniformly asymptotically stable.

Copyright Elsevier 2022

5.3 Perturbed linear systems

Suppose we know about the stability of the zero solution of the linear system

$$x'(t) = A(t)x(t), \ t \geq 0. \tag{5.3.1}$$

The question is, what can we say about the stability of the zero solution of the *perturbed* linear system

$$x'(t) = A(t)x(t) + B(t)x(t), \ t \geq 0, \tag{5.3.2}$$

where A and B are $n \times n$ continuous matrices on the interval $[0, \infty)$? In other words, under what conditions on $B(t)$ is the perturbed system (5.3.2) stable? It turns out that if, in some sense, the norm of the matrix B is small, then a type of stability of (5.3.2) can be deduced. Note that in (5.3.2), $B(t)$ is known as the *perturbation term*.

Theorem 5.3.1. *Assume that the zero solution of* (5.3.1) *is uniformly sable and that*

$$\int_0^\infty ||B(t)||dt \leq E \tag{5.3.3}$$

for some positive constant E. Then the zero solution of (5.3.2) *is uniformly stable.*

Proof. Let $\Phi(t)$ be the fundamental matrix of (5.3.1). Due to the US of the zero solution, for some positive constant K, we have

$$||\Phi(t)\Phi^{-1}(s)|| \leq K.$$

By the variation of parameters formula (3.3.4), we have that

$$x(t) = \Phi(t)\Phi^{-1}(t_0)x_0 + \int_{t_0}^t \Phi(t)\Phi^{-1}(s)B(s)ds$$

or

$$\begin{aligned} |x(t)| &= ||\Phi(t)\Phi^{-1}(t_0)|||x_0| + \int_{t_0}^t ||\Phi(t)\Phi^{-1}(s)||\,||B(s)||\,|x(s)|ds \\ &\leq K|x_0| + \int_{t_0}^t K||B(s)||\,|x(s)|ds \\ &\leq K|x_0|e^{\int_{t_0}^t K||B(s)||\,ds} \quad \text{(by Gronwall's inequality)} \\ &\leq K|x_0|e^{KE}, \end{aligned} \tag{5.3.4}$$

which implies the uniform stability. This completes the proof. □

The next example shows that the integrability condition (5.3.3) for $||B(t)||$ is necessary.

Copyright Elsevier 2022

Example 5.2. Letting

$$x_1' = x_2,$$

the second-order differential equation

$$x'' + x = 0$$

can be written in the matrix form

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

with

$$x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

Thus its zero solution is uniformly stable. On the other hand, Theorem 5.3.1 says nothing about the perturbed system

$$x'' - \frac{2}{t}x' + x = 0, \ t > 0,$$

which is equivalent to

$$x'(t) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} x + \begin{pmatrix} 0 & 0 \\ 0 & \frac{2}{t} \end{pmatrix} x.$$

Here $B(t) = \begin{pmatrix} 0 & 0 \\ 0 & \frac{2}{t} \end{pmatrix}$ is the perturbed matrix in the sense that $|B(t)| = \frac{2}{t} \to 0$ as $t \to \infty$. Moreover,

$$\int_{t^*}^{\infty} ||B(t)||dt = \int_{t^*}^{\infty} \frac{2}{t} dt = \infty$$

for any $t^* > 0$, and hence $B(t)$ does not satisfy condition (5.3.3).

Note that the perturbed system has two linearly independent solutions

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} \sin(t) - t\cos(t) \\ t\sin(t) \end{pmatrix}, \ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} \cos(t) + t\sin(t) \\ t\cos(t) \end{pmatrix},$$

and consequently its solutions are unbounded, and as a result, its zero solution is unstable.

Theorem 5.3.2. *Assume that the zero solution of* (5.3.1) *is uniformly asymptotically stable, that is, if* $\Phi(t)$ *is the fundamental matrix of* (5.3.1)*, then by* (4.2.3) *there are positive constants* K *and* ξ *such that*

$$||\Phi(t)\Phi^{-1}(s)|| \leq K e^{\xi(t-s)}, \ t \geq s \geq 0.$$

Copyright Elsevier 2022

Suppose

$$\int_0^{\infty} ||B(t)||dt \le \gamma(t-t_0)+\beta,\ \ t \ge t_0 \ge 0, \tag{5.3.5}$$

for positive constants γ and β. Then the zero solution of (5.3.2) *is uniformly asymptotically stable, provided that*

$$\gamma < \frac{\xi}{K}.$$

Proof. Imitate the proof of Theorem 5.3.1 and get

$$|x(t)|e^{\xi(t-t_0)} \le K|x_0| + \int_{t_0}^{t} Ke^{\xi(s-t_0)}\, ||B(s)||\, |x(s)|ds.$$

Using Gronwall's inequality along with condition (5.3.5), we arrive at

$$|x(t)| \le Ke^{K\beta}|x_0|e^{K(\gamma-\frac{\xi}{K})(t-t_0)}. \tag{5.3.6}$$

The rest of the proof follows along the lines of Theorem 5.2.2 using inequality (5.3.6). This completes the proof. ☐

5.4 Autonomous systems in the plane

In most applications, the corresponding modeling systems can be written as two-dimensional autonomous systems in the form

$$x' = P(x,y),\ \ y' = Q(x,y), \tag{5.4.1}$$

where P and Q are continuous on some subset of $\mathbb{R}^2$. Recall that the system is called *autonomous* if P and Q do not depend explicitly on t. System (5.4.1) can be written in the form $z' = f(z)$, where

$$z = \begin{pmatrix} x \\ y \end{pmatrix} \text{ and } f(z) = \begin{pmatrix} P(z) \\ Q(z) \end{pmatrix}.$$

Thus the second-order differential equation

$$x'' = g(x,x')$$

can be written in the form (5.4.1) as the system

$$x' = y,\ \ y' = g(x,y).$$

We begin with the following lemma. We denote the solution of (5.4.1) by the pair $(x(t), y(t)),\ t \in (a,b)$.

Copyright Elsevier 2022

Lemma 5.3. *Let* $(x(t), y(t))$ *be a solution of* (5.4.1). *Then for any constant* k*, the pair* $(x(t+k), y(t+k))$ *is also a solution of* (5.4.1).

Proof. Let $x_1 = x(t+k)$ and $x_2 = y(t+k)$. Then by the chain rule we have

$$\begin{aligned} x_1' &= x'(t+k) = P(x(t+k), y(t+k)) = P(x_1, x_2), \\ x_2' &= y'(t+k) = Q(x(t+k), y(t+k)) = Q(x_1, x_2), \end{aligned}$$

which imply that the pair $(x_1(t), x_2(t))$ is a solution of (5.4.1) for $t \in (a-k, b-k)$. This completes the proof. ☐

The results of Lemma 5.3 do not hold for non-autonomous systems. To see this, we consider the system

$$x' = ty, \ \ y' = y.$$

It readily follows that

$$x(t) = (t-1)e^t, \ \ y(t) = e^t$$

is a solution of the system. However, for any nonzero constant k, we have $x(t+k) = (t+k-1)e^{t+k}$ and $x'(t+k) = (t+k)e^{t+k} \neq ty(t)$.

Definition 5.4.1. The solution $(x(t), y(t))$ of (5.4.1) as t varies describes parametrically a curve in the plane, which we call a *trajectory* (or orbit).

Theorem 5.4.1. *Different trajectories of* (5.4.1) *cannot intersect.*

Proof. Let C_1 and C_2 be two trajectories represented by $(x_1(t), y_1(t))$ and $(x_2(t), y_2(t))$, respectively, with a common point (x_0, y_0). Then there are two different times (otherwise, uniqueness is violated), say t_1 and t_2, such that

$$(x_0, y_0) = (x_1(t_1), y_1(t_1)) = (x_2(t_2), y_2(t_2)).$$

By Lemma 5.3

$$x(t) = x_1(t + t_1 - t_2), \ \ y(t) = y_1(t + t_1 - t_2)$$

is a solution. Since $(x(t_2), y(t_2)) = (x_0, y_0)$, we have that $x(t)$ and $y(t)$ must agree respectively with $x_2(t)$ and $y_2(t)$ due to the uniqueness. Thus C_1 and C_2 must coincide. This completes the proof. ☐

Remark 5.3. Be aware that a trajectory is a curve represented parametrically by one or more solutions. Thus $x(t), y(t)$ and $x(t+k), y(t+k)$ for $k \neq 0$ represent distinct solutions but the same trajectory.

Example 5.3. The damped harmonic motion represented by the second-order differential equation

$$u'' + 2u' + 2u = 0$$

Copyright Elsevier 2022

can be easily transformed into the planar autonomous system

$$\begin{aligned} x' &= y, \\ y' &= -2x - 2y. \end{aligned}$$

The eigenvalues of the system are found to be $\lambda = -1 \pm i$. Hence the solution is

$$\begin{aligned} x &= e^{-t}\left(c_1 \cos(t) + c_2 \sin(t)\right), \\ y &= e^{-t}\left(-c_1 \sin(t) + c_2 \cos(t)\right). \end{aligned}$$

To describe the trajectories, we find that

$$x^2 + y^2 = (c_1^2 + c_2^2)e^{-2t},$$

which describes a family of spirals.

We begin a detailed study of the linear plane autonomous system

$$X' = AX, \tag{5.4.2}$$

where

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

is a nonsingular matrix, and

$$X = \begin{pmatrix} x \\ y \end{pmatrix}.$$

The characteristic equation for this system is

$$\lambda^2 - (a+d)\lambda + ad - bc = 0.$$

By introducing

$$\begin{aligned} p &= a + d, \\ q &= ad - bc, \end{aligned}$$

the characteristic equation becomes

$$\lambda^2 - p\lambda + q = 0.$$

Let λ_1 and λ_2 be the roots of this equation,

$$\lambda_{1,2} = \frac{1}{2}\left[p \pm \sqrt{p^2 - 4q}\right]. \tag{5.4.3}$$

Copyright Elsevier 2022

It is obvious that the signs of $\lambda_{1,2}$ and hence the stability of the zero solution depend on the discriminant

$$\Delta = p^2 - 4q = (\mathrm{tr}(A))^2 - 4\det(A).$$

Based on Theorem 5.1.4, we can now state the following stability theorem of the zero solution of (5.4.2).

Theorem 5.4.2. *The zero solution of* (5.4.2) *is*

a) asymptotically stable if any of the followings occurs:
i)

$$\Delta > 0,\ q > 0,\ \textit{and}\ p < 0,$$

ii)

$$\Delta = 0,\ p < 0,$$

iii)

$$\Delta < 0,\ p < 0;$$

b) stable if

$$\Delta < 0,\ p = 0;$$

c) unstable if any of the followings occurs:
i)

$$\Delta > 0,\ q > 0,\ \textit{and}\ p > 0,$$

ii)

$$\Delta = 0,\ p > 0,$$

iii)

$$\Delta < 0,\ p > 0.$$

Remark 5.4. In the case where $p = 0$ and $q = 0$, further analysis is required to determine the stability of the zero solution.

Note that according to Theorem 5.4.2, the zero solution $(0, 0)$ of the system in Example 5.3 is asymptotically stable.

Next, we consider the behavior of the trajectories of system (5.4.2) for various cases of the eigenvalues. In what follows, we use the matrix transformation

$$Y = BX,\ \ \det(B) \neq 0,$$

so that the essential behavior near the critical point $(0, 0)$ remains unchanged.

Copyright Elsevier 2022

1. *Real and distinct roots.* If we let

$$B = \begin{pmatrix} c & \lambda_1 - a \\ c & \lambda_2 - a \end{pmatrix},$$

then system (5.4.2) transforms into the system

$$\begin{aligned} x' &= \lambda_1 x, \\ y' &= \lambda_2 y, \end{aligned}$$

where, for simplicity, x and y are again used as the new coordinates. For some arbitrary constants c_1 and c_2, the solutions of the system are

$$x(t) = c_1 e^{\lambda_1 t}, \quad y(t) = c_2 e^{\lambda_2 t}. \tag{5.4.4}$$

Eliminating the time t in (5.4.4) gives

$$y = c x^{\frac{\lambda_2}{\lambda_1}}, \tag{5.4.5}$$

where c is an arbitrary constant. When λ_1 and λ_2 have the same sign, then Eq. (5.4.5) represent parabolic curves that are tangent to the origin as shown in Fig. 5.1(a). The origin is called a *proper node*. We have the following three subcases.
1.(a) If both λ_1, λ_2 are negative, then the origin is asymptotically stable. In this case, we have a *stable node*.
1.(b) If λ_1, λ_2 are positive, then the origin is unstable. In this case, we have an *unstable node*.
1.(c) If λ_1, λ_2 have opposite signs, then (5.4.5) represents hyperbolic curves as shown in Fig. 5.1(b). The origin is unstable and is called a *saddle point*.

2. *Real and equal roots.* In this case, $\Delta = (a - d)^2 + 4bc = 0$, which implies that

$$\lambda_1 = \lambda_2 = \frac{(a + d)}{2} := \lambda.$$

2. (a) If b or $c = 0$ and $a = d$, then system (5.4.2) reduces to

$$\begin{aligned} x' &= \lambda x, \\ y' &= \lambda y. \end{aligned}$$

As before, solving the system and eliminating t lead to the trajectories that are lines through the origin given by

$$y = \frac{c_2}{c_1} x.$$

Thus, if $\lambda < 0$, then the origin is asymptotically stable and is a *proper node*, as shown in Fig. 5.1(c). If $\lambda > 0$, then the origin is unstable.

Copyright Elsevier 2022

(b) This is a more complicated case. If we let

$$B = \begin{pmatrix} \frac{a-d}{2b} & 1 \\ \frac{1}{b} & 0 \end{pmatrix}, \; b \neq 0,$$

then system (5.4.2) transforms into the system

$$\begin{aligned} x' &= \lambda x, \\ y' &= x + \lambda y. \end{aligned}$$

For some arbitrary constants c_1 and c_2, the solutions of the system are

$$x(t) = c_1 e^{\lambda t}, \;\; y(t) = (c_1 t + c_2) e^{\lambda t}. \tag{5.4.6}$$

The trajectories are shown in Fig. 5.1(d), and the origin is an *improper node*; it is asymptotically stable when $\lambda < 0$ and unstable when $\lambda > 0$.

3. *Complex roots.* In this case, we let

$$\lambda_1 = \alpha + i\beta \;\text{ and }\; \lambda_2 = \alpha - i\beta$$

and choose the matrix

$$B = \begin{pmatrix} c & \alpha - a \\ 0 & \beta \end{pmatrix}$$

so that system (5.4.2) transforms into

$$\begin{aligned} x' &= \alpha x - \beta y, \\ y' &= \beta x + \alpha y. \end{aligned}$$

3. (a) For $\alpha = 0$, this system becomes

$$\begin{aligned} x' &= -\beta y, \\ y' &= \beta x, \end{aligned}$$

with solutions

$$x(t) = c_1 \cos(\beta t) + c_2 \sin(\beta t), \;\; y(t) = c_1 \sin(\beta t) + c_2 \cos(\beta t)$$

for arbitrary constants c_1 and c_2. It is easy to verify that the trajectories are circles given by

$$x^2 + y^2 = c_1^2 + c_2^2$$

and are shown in Fig. 5.1(e). In this case the origin is stable but not asymptotically stable.

Copyright Elsevier 2022

3. (b) For $\alpha \neq 0$, the above system has the solutions

$$x(t) = e^{\alpha t}(c_1 \cos(\beta t) + c_2 \sin(\beta t)), \quad y(t) = e^{\alpha t}(c_1 \sin(\beta t) + c_2 \cos(\beta t))$$

for arbitrary constants c_1 and c_2. The trajectories are spirals given by

$$x^2 + y^2 = (c_1^2 + c_2^2)e^{2\alpha t}$$

and are shown in Fig. 5.1(f). In this case the origin is a *focal point*, which is asymptotically stable when $\alpha < 0$ and unstable when $\alpha > 0$.

The solutions of a planar system of linear differential equations can be classified according to the trace and the determinant of the coefficient matrix. This diagram schematically shows the different types of solutions.

5.5 Hamiltonian and gradient systems

Consider the pendulum with friction discussed in Example 3.5:

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= -\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2. \end{aligned}$$

Define the *energy function* $H : [t_0, \alpha) \times \mathbb{R}^2 \to [0, \infty)$ by

$$H(x_1, x_2) = \frac{1}{2}x_2^2(t) + \frac{g}{L}\Big(1 - \cos(x_1(t))\Big).$$

Copyright Elsevier 2022

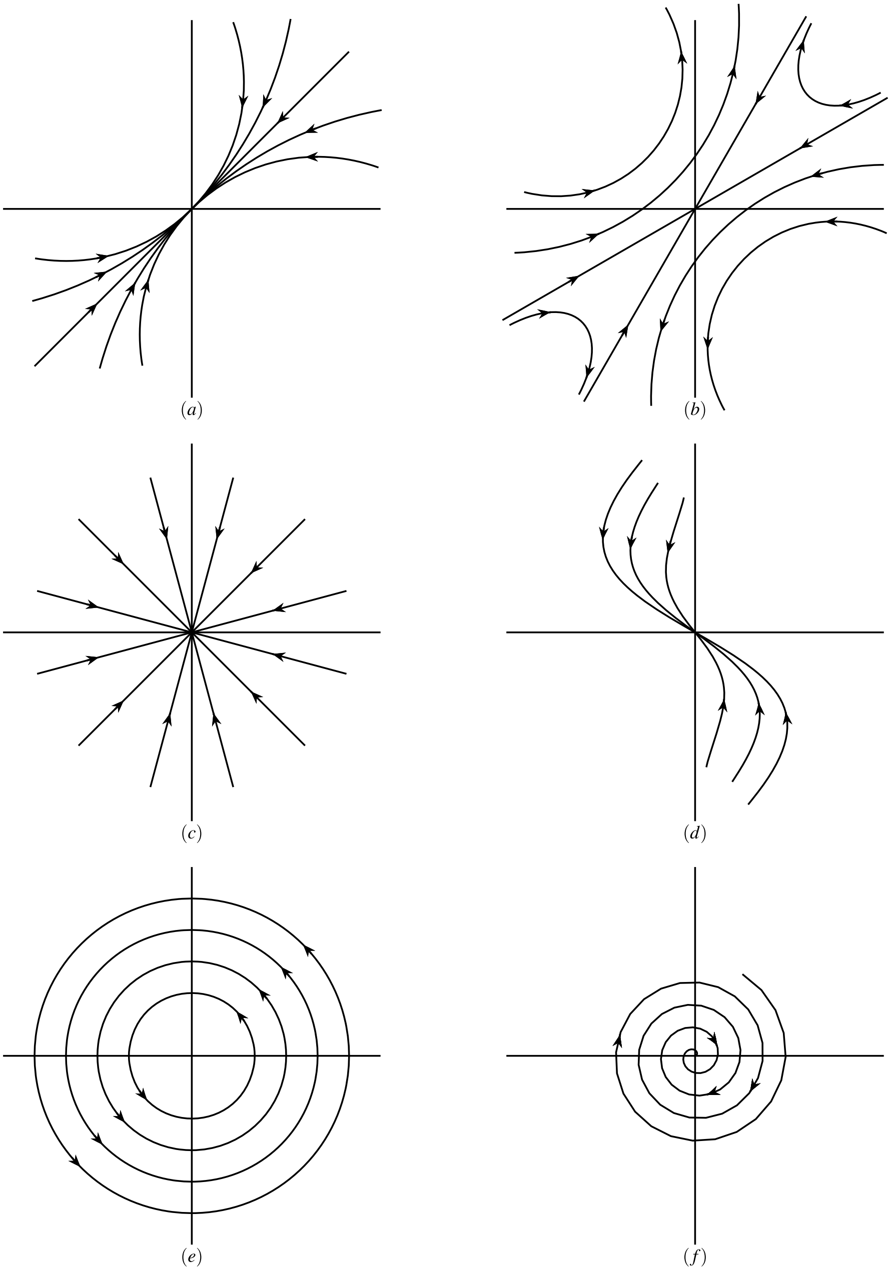

FIGURE 5.1

A phase portrait gallery.

Copyright Elsevier 2022

Then along the solutions of (3.2.7) we have that

$$\begin{aligned}\frac{d}{dt}H(x_1,x_2) &= x_2\,x_2' + \frac{g}{L}\sin(x_1)\,x_1'\\ &= x_2\Big(-\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2\Big) + \frac{g}{L}\sin(x_1)x_2\\ &= -\frac{b}{m}x_2^2.\end{aligned}$$

If the friction $b > 0$, then $\frac{d}{dt}H(t) < 0$, and the *energy is dissipated*. On the other hand, if $b = 0$, then the energy is *conserved*, and theoretically, this solution lies on a *level curve*

$$H(x_1(t), x_2(t)) = \text{constant} := c$$

of the function $H(x_1, x_2)$ with variables x_1 and x_2. Thus, in the case $b > 0$, this solution will not stay on a level curve. Hence centers are possible for (3.2.5).

When the energy is conserved, we obtain an example of a *Hamiltonian system*. In our situation the system

$$\begin{cases} x_1' = x_2, \\ x_2' = -\frac{g}{L}\sin(x_1) \end{cases} \tag{5.5.1}$$

can be written in the form

$$\begin{aligned} x_1' = x_2 &= \frac{\partial H}{\partial x_2},\\ x_2' = -\frac{g}{L}\sin(x_1) &= -\frac{\partial H}{\partial x_1}.\end{aligned}$$

Since the Hamiltonian function conserves the energy, it is constant along solutions. The level curves are given by

$$\frac{1}{2}x_2^2(t) - \frac{g}{L}\cos(x_1(t)) = c.$$

System (5.5.1) has the equilibrium solutions $(\pm n\pi, 0)$, $n = 0, 1, \ldots$. It will be shown in Chapter 6, when there is no damping or friction, that is, $b = 0$, then $(\pm n\pi, 0)$ are centers for $n = 2, 4, 6, \ldots$ and unstable saddles for $n = 1, 3, 5, \ldots$. Phase portraits and level curves are shown in Fig. 5.2 for different values of c.

Thus we have the following definition.

Definition 5.5.1. A planar system of differential equations is called a *Hamiltonian system* if there exists a differentiable function $H(x_1, x_2) : \mathbb{R}^2 \to \mathbb{R}$ such that

$$\begin{cases} x_1'(t) = \frac{\partial H}{\partial x_2}, \\ x_2'(t) = -\frac{\partial H}{\partial x_1}. \end{cases} \tag{5.5.2}$$

Such a function $H(x_1, x_2)$ is called a *Hamiltonian function* of system (5.5.2).

Copyright Elsevier 2022

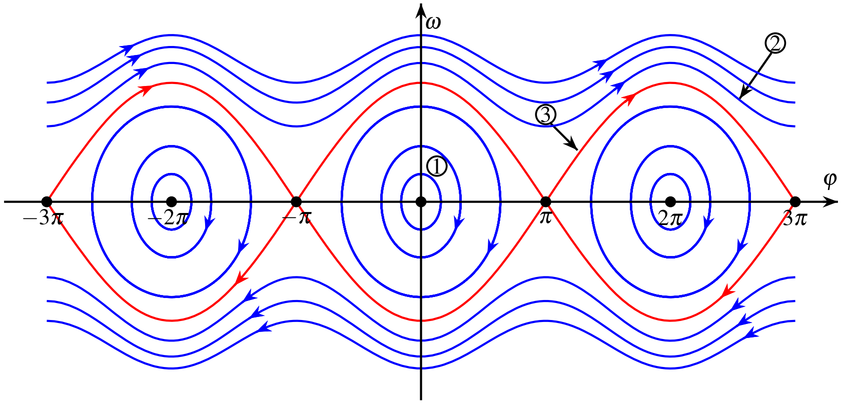

FIGURE 5.2

Phase portraits and level curves for (5.5.1) for different values of c.

Consider the second-order differential equation of the form

$$x'' - f(x)x' - g(x) = 0.$$

In system form, we have

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= g(x_1) + f(x_1)x_2. \end{aligned}$$

Let

$$H(x_1, x_2) = \frac{1}{2}x_2^2(t) + \left(-\int_0^{x_1} g(s)ds\right),$$

where $\frac{1}{2}(x')^2$ corresponds to the *kinetic energy*, and $-\int_0^{x(t)} g(s)ds$ represents the *potential energy*. Then it is easy to verify that

$$\begin{aligned} x_1' &= x_2 = \frac{\partial H}{\partial x_2}, \\ x_2' &= g(x_1) + f(x_1)x_2 = -\frac{\partial H}{\partial x_1}, \end{aligned}$$

only if $f(x) = 0$. We conclude that the *Newtonian system*

$$x'' = g(x)$$

with g continuously differentiable on $\mathbb{R}$ is a Hamiltonian system.

Copyright Elsevier 2022

For the Hamiltonian system (5.5.2), the energy is always conserved. To see this, let $(x_1(t), x_2(t))$ be any solution of (5.5.2). Then

$$\begin{aligned} \frac{d}{dt}H(x_1(t), x_2(t)) &= \frac{\partial H}{\partial x_1}x_1' + \frac{\partial H}{\partial x_2}x_2' \\ &= \frac{\partial H}{\partial x_1}\frac{\partial H}{\partial x_2} + \frac{\partial H}{\partial x_2}\left(-\frac{\partial H}{\partial x_1}\right) = 0. \end{aligned} \tag{5.5.3}$$

That is why a Hamiltonian function is sometimes called an *energy function*. In applications, the Hamiltonian function is defined by

$$H(x, y) = K(x, y) + V(x, y),$$

where K is the kinetic energy, and V is the potential energy.

Next, we establish conditions for the planar system

$$x' = f(x, y), \quad y' = g(x, y) \tag{5.5.4}$$

to be a Hamiltonian system. If (5.5.4) is a Hamiltonian system, then there is a function H satisfying

$$\frac{\partial H}{\partial y} = f(x, y) \text{ and } -\frac{\partial H}{\partial x} = g(x, y).$$

Assuming that the function H has continuous second-order partial derivatives, we arrive at

$$\frac{\partial f}{\partial x} = \frac{\partial^2 H}{\partial x \partial y} = \frac{\partial^2 H}{\partial y \partial x} = -\frac{\partial g}{\partial y}. \tag{5.5.5}$$

Thus we have shown that condition (5.5.5) is a sufficient condition for system (5.5.4) to be a Hamiltonian system.

The system

$$\begin{aligned} x' &= x + y^2, \\ y' &= -y - x^2 \end{aligned}$$

is Hamiltonian since $\frac{\partial f}{\partial x} = 1 = -\frac{\partial g}{\partial y} = -(-1)$.

The next theorem provides necessary and sufficient conditions for the existence of Hamiltonian function.

Theorem 5.5.1. *The planar system* (5.5.4) *is a Hamiltonian system if and only if*

$$\frac{\partial f}{\partial x} = -\frac{\partial g}{\partial y}. \tag{5.5.6}$$

Proof. We already know that if system (5.5.4) is Hamiltonian, then (5.5.6) is true. It remains to show that if (5.5.4) holds, then there is $H(x, y)$ satisfying

$$x'(t) = \frac{\partial H}{\partial y} = f(x, y)$$

Copyright Elsevier 2022

and

$$y'(t) = -\frac{\partial H}{\partial x} = g(x, y).$$

Let us begin with $\frac{\partial H}{\partial x} = -g(x, y)$. Then a direct integration with respect to x keeping y fixed gives

$$H(x, y) = -\int g(x, y)dx + C_1(y),$$

where the constant of integration C_1 may depend on y since H is a function of two variables x and y. Once we determine C_1, we can obtain H. Differentiating the last expression in H with respect to y and setting it equal to $f(x, y)$ leads to

$$\frac{\partial H}{\partial y} = \frac{\partial}{\partial y}\Big(-\int g(x, y)dx + C_1(y)\Big) = f(x, y) \text{ by definition}$$

or

$$C_1'(y) = \frac{\partial}{\partial y}\int g(x, y)dx + f(x, y).$$

Then integrating the last expression with respect to y gives the desired function $C_1(y)$, that is,

$$C_1(y) = \int \Big(\frac{\partial}{\partial y}\int g(x, y)dx\Big)dy + \int f(x, y)dy.$$

The proof will be accomplished if we can show $C_1(y)$ does not depend on x. Equivalently, we can show that the right side of the above expression is independent of x:

$$\begin{aligned}
&\frac{\partial}{\partial x}\Big[\int f(x, y)dy + \int \Big(\frac{\partial}{\partial y}\int g(x, y)dx\Big)dy\Big] \\
&= \int \frac{\partial f}{\partial x}dy + \int \frac{\partial}{\partial x}\Big(\frac{\partial}{\partial y}\int g(x, y)dx\Big)dy \\
&= \int \frac{\partial f}{\partial x}dy + \int \frac{\partial}{\partial y}\Big(\frac{\partial}{\partial x}\int g(x, y)dx\Big)dy \\
&= \int \frac{\partial f}{\partial x}dy + \int \frac{\partial g}{\partial y}dy \\
&= \int \frac{\partial f}{\partial x}dy - \int \frac{\partial f}{\partial x}dy = 0.
\end{aligned}$$

This completes the proof. □

Example 5.4. We already know that the system

$$x' = x + y^2, \;\; y' = -y - x^2$$

Copyright Elsevier 2022

is Hamiltonian since $\frac{\partial f}{\partial x} = 1 = -\frac{\partial g}{\partial y} = -(-1)$. Let us now try to find the Hamiltonian function H. It follows from Theorem 5.5.1 that

$$H(x,y) = -\int g(x,y)dx + C_1(y) = -\int (-y-x^2)dx + c_1(y) = xy + \frac{x^3}{3} + C_1(y),$$

where

$$C_1'(y) = \frac{\partial}{\partial y}\int g(x,y)dx + f(x,y) = \frac{\partial}{\partial y}\Big(\int (-y-x^2)dx\Big) + x + y^2.$$

It follows that $C_1(y) = \frac{y^3}{3}$. Finally,

$$H(x,y) = xy + \frac{x^3}{3} + \frac{y^3}{3}.$$

Next, we try to explore the stability of an equilibrium solution of a Hamiltonian system. We have seen that the autonomous system (5.5.4) is called Hamiltonian or conservative if there exists a Hamiltonian function $H : \Omega \to \mathbb{R}$ that is not constant on any open set in Ω, but it follows from (5.5.3) that it is constant on solutions (orbits).

Theorem 5.5.2. *Suppose* (5.5.4) *is a Hamiltonian system. Then none of its equilibrium solutions can be asymptotically stable.*

Proof. Suppose q is an asymptotically stable equilibrium solution or a point of the Hamiltonian system given by (5.5.4). Then there is a neighborhood Λ of q such that for $p \in \Lambda$, $\phi(t,p) \to q$ as $t \to \infty$, where $\phi(t,p)$ is an orbit or trajectory through p. However, if the system is assumed conservative with Hamiltonian function H, then H is constant on orbits, so $H(p) = H(\phi(t,p)) = H(q)$ for each $p \in \Lambda$. This implies that H is constant on an open set, which is a contradiction. This completes the proof. □

When a Hamiltonian system has an equilibrium point at which the integral has a minimum, then an inference of stability can be made.

Definition 5.5.2. A function $E : \Omega \to \mathbb{R}$ is said to have a *strong minimum* at q if there is a neighborhood Λ of q such that $E(x) > E(q)$ for every $x \in \Lambda$ except for $x = q$.

The name *strong* is implied from the strict inequality.

Theorem 5.5.3. *Suppose* (5.5.4) *is a Hamiltonian system with equilibrium solution q and Hamiltonian function H. If H has a strong minimum at q, then q is stable.*

Proof. Shift the equilibrium solution q to the origin $(0,0)$. Let Λ be a neighborhood of $(0,0)$. Let $\varepsilon > 0$ be small enough such that the set $A = \{d : ||d|| = \varepsilon\} \subset \Lambda$. Set

$$V(d) = H(d) - H(0).$$

Copyright Elsevier 2022

Denote the minimum of V on the set A by V_ε. Now we chose $\delta > 0$ with $\delta < \varepsilon$, so that we have $V(d) < \varepsilon$ if $||d|| < \delta$. Then we have $||d(t)|| < \varepsilon$ for all $t > 0$. This implies that the origin is stable. This completes the proof. ☐

Next, we state parallel results concerning strong maximums and saddle points.

Definition 5.5.3. A function $E : \Omega \to \mathbb{R}$ is said to have a *strong maximum* at q if there is a neighborhood Λ of q such that $E(q) > E(x)$ for every $x \in \Lambda$ except for $x = q$.

The name *strong* is implied from the strict inequality.

Theorem 5.5.4. *Suppose* (5.5.4) *is a Hamiltonian system with equilibrium solution q and Hamiltonian function H. If H has a strong maximum at q, then q is an unstable saddle.*

Remark 5.5. Note that if (x_0, y_0) is a critical point of (5.5.4), then it will also be a critical point of the Hamiltonian function H. We can use the second derivative test again to determine whether or not $H(x, y)$ has a saddle at (x_0, y_0) or a maximum or a minimum there. The Jacobian at the critical point is

$$J(x_0, y_0) = \begin{pmatrix} H_{xy}(x_0, y_0) & H_{yy}(x_0, y_0) \\ -H_{xx}(x_0, y_0) & -H_{xy}(x_0, y_0) \end{pmatrix}.$$

Furthermore,

$$\det J(x_0, y_0) = -\Big(H_{xy}(x_0, y_0)\Big)^2 + H_{xx}(x_0, y_0)H_{yy}(x_0, y_0).$$

Recall from Section 4.3.1 that if λ_1 and λ_2 are eigenvalues of $J(x_0, y_0)$, not necessarily distinct, then $\det J(x_0, y_0) = \lambda_1\lambda_2$. Thus if we assume that none of the eigenvalues of the $J(x_0, y_0)$ is zero, then we have $\det J(x_0, y_0) \neq 0$.

If $\det J(x_0, y_0) > 0$, which is the same as saying that the function H has a strict minimum or maximum at (x_0, y_0), then (x_0, y_0) is a stable center for (5.5.4) if both eigenvalues are negative. This is the case since by Theorem 5.5.2 no critical point of a Hamiltonian system can be asymptotically stable. If the both eigenvalues are positive, then (x_0, y_0) is unstable for (5.5.4).

If $\det(x_0, y_0) < 0$, the equilibrium point (x_0, y_0) is unstable saddle for (5.5.4).

Consider the Hamiltonian system given in Example 5.4. We have already found the Hamiltonian function

$$H(x, y) = xy + \frac{x^3}{3} + \frac{y^3}{3}.$$

The two equilibrium solutions are $(0, 0)$ and $(-1, -1)$. Define

$$D(x, y) = H_{xx}H_{yy} - \Big(H_{xy}\Big)^2.$$

Copyright Elsevier 2022

Then

$$D(x, y) = 4xy - 1.$$

Now $D(0,0) = -1$, and $(0,0)$ is an unstable saddle. On the other hand, $D(-1-1) = 3 > 0$, and since $H_{xx}(-1,-1) = -2 < 0$, the Hamiltonian function has a strong maximum at the equilibrium solution $(-1,-1)$. Thus by Theorem 5.5.4 $(-1,-1)$ is unstable.

Next, we discuss dissipative systems that we call *gradient systems*.

Definition 5.5.4. A planar system of differential equations is called *gradient* if there exists a differentiable function $V(x, y) : \mathbb{R}^2 \to \mathbb{R}$ such that

$$\begin{cases} x'(t) = -\frac{\partial V}{\partial x}, \\ x_2'(t) = -\frac{\partial V}{\partial y}. \end{cases} \tag{5.5.7}$$

The function $V(x, y)$ is called the *gradient function* of system (5.5.7).

The name *gradient* comes from the fact that system (5.5.7) can be written in the form

$$X' = -\nabla V,$$

where

$$X = \begin{pmatrix} x \\ y \end{pmatrix}, \quad \nabla V = \begin{pmatrix} \frac{\partial V}{\partial x} \\ \frac{\partial V}{\partial y} \end{pmatrix}.$$

For the gradient system (5.5.7), the energy is dissipated. To see this, assume that V is an energy function for system (5.5.7). Then if $(x(t), y(t))$ is any solution of (5.5.7), then

$$\begin{aligned} \frac{d}{dt} V(x(t), y(t)) &= \frac{\partial V}{\partial x} x' + \frac{\partial V}{\partial y} y' \\ &= -\left[\left(\frac{\partial V}{\partial x}\right)^2 + \left(\frac{\partial V}{\partial y}\right)^2\right] < 0, \end{aligned} \tag{5.5.8}$$

provided that $\left(\frac{\partial V}{\partial x}\right)^2 + \left(\frac{\partial V}{\partial y}\right)^2 \neq 0$.

Next, we establish conditions for the planar system

$$x' = f(x, y), \quad y' = g(x, y) \tag{5.5.9}$$

to be a gradient system. If (5.5.9) is a gradient system, then there is a function V satisfying

$$-\frac{\partial V}{\partial x} = f(x, y) \text{ and } -\frac{\partial V}{\partial y} = g(x, y).$$

Copyright Elsevier 2022

Assuming that the function V has continuous second-order partial derivatives, we arrive at

$$\frac{\partial f}{\partial y} = -\frac{\partial^2 V}{\partial x \partial y} = -\frac{\partial^2 V}{\partial y \partial x} = \frac{\partial g}{\partial x}. \tag{5.5.10}$$

Thus we have shown that condition (5.5.10) is a sufficient condition for system (5.5.9) to be a gradient system. The system of differential equations

$$x' = -2xy, \quad y' = -(x^2 - 1)$$

is gradient since $\frac{\partial f}{\partial y} = -2x = \frac{\partial g}{\partial x}$. Following parallel steps as in Theorem 5.5.1, we easily find the gradient function

$$V(x, y) = x^2 y - y.$$

Note that

$$\frac{dV}{dt} = 2xyx' + (x^2 - 1)y' = -[4x^2y^2 + (x^2 - 1)^2] = -[V_x^2 + V_y^2] < 0$$

for $V_x^2 + V_y^2 \neq 0$. As in the case of a Hamiltonian system, if (x_0, y_0) is a critical point of (5.5.9), then it will also be a critical point of the gradient function V. Now we state parallel theorems to Theorems 5.5.3 and 5.5.4.

Theorem 5.5.5. *Suppose* (5.5.9) *is a gradient system with equilibrium solution q and gradient function H. If H has a strong minimum at q, then q is stable.*

Theorem 5.5.6. *Suppose* (5.5.9) *is a gradient system with equilibrium solution q and gradient function H. If H has a strong maximum at q, then q is an unstable saddle.*

Example 5.5. Consider the system

$$x' = -8x^3 + 2x, \quad y' = -2y + 2,$$

which is gradient with gradient function

$$V(x, y) = 2x^4 + y^2 - x^2 - 2y.$$

The system has three equilibrium solutions given by $(-1/2, 1)$, $(0, 1)$, $(1/2, 1)$. Using the second derivative test, we find that V has a strong minimum at $(-1/2, 1)$ and $(1/2, 1)$. Thus by Theorem 5.5.5 the points are stable for the system. The gradient function V has neither a maximum nor a minimum at $(0, 1)$ and hence nothing can be concluded about the stability of $(0, 1)$. We will see in Chapter 6 that $(0, 1)$ is unstable.

5.6 Exercises

Exercise 5.1. Assume that every eigenvalue of an $n \times n$ constant matrix A has a non-positive real part and that the eigenvalues with zero real part are simple. Suppose that $g : [0, \infty) \to \mathbb{R}^n$ is continuous with

$$\int_0^t |g(s)|ds < \infty.$$

Then show that every solution of

$$x'(t) = Ax(t) + g(t)$$

is bounded on $[0, \infty)$.

Exercise 5.2. Prove (iii) of Theorem 5.1.4.

Exercise 5.3. Examine the stability of the zero solution of the given system.

(a)

$$x'(t) = \begin{pmatrix} 0 & 2 & 1 \\ -2 & 0 & -1 \\ 0 & 0 & -1 \end{pmatrix} x;$$

(b)

$$x'(t) = \begin{pmatrix} 1 & 2 & 1 \\ 6 & -1 & 0 \\ -1 & -2 & -1 \end{pmatrix} x;$$

(c)

$$x'(t) = \begin{pmatrix} 6 & -1 \\ 5 & 2 \end{pmatrix} x.$$

Exercise 5.4. Show that the zero solution of the non-autonomous system

$$x'(t) = \begin{pmatrix} -1 + te^{-t} & 2 + e^{-t} \\ 2 + \frac{1}{(1+t)^2} & -4 + (1+t)^{\frac{-1}{2}} \end{pmatrix} x$$

is stable.

Exercise 5.5. Assume all the eigenvalues of the matrix A of system (5.2.3) have negative real parts and there is a positive number θ such that $||A(t) - A|| < \theta$ for t is sufficiently large. Show that solutions of (5.2.2) are bounded and its zero solution is asymptotically stable.

Copyright Elsevier 2022

Exercise 5.6. Let A be a constant matrix with $Re(\rho(A)) < 0$. Choose constants $K > 0$ and $\alpha < 0$ such that

$$||e^{At}|| \le Ke^{\alpha t}, \ \ t \ge 0.$$

Let C be a continuous matrix-valued function such that for positive constant β, we have

$$||C(t)|| \le \frac{\beta}{K}, \ \ t \ge 0.$$

Show that the zero solution of

$$x' = [A + C(t)]x(t)$$

is

1. stable if $\beta = -\alpha$,
2. unstable if $\beta > -\alpha$, and
3. asymptotically stable if $0 < \beta < -\alpha$.

Exercise 5.7. a) Let A be a constant matrix with $Re(\rho(A)) < 0$. Let C be a continuous matrix-valued function on $[0, \infty)$. Show that if

$$\int_0^\infty ||C(t)||dt < \infty,$$

then the zero solution of

$$x' = [A + C(t)]x(t)$$

is asymptotically stable.

b) Use the results of part a) to show that the zero solution of

$$u''(t) + \left(\frac{1}{t^2+1} + 1\right)u'(t) + \left(e^{-t} + 1\right)u(t) = 0$$

is asymptotically stable for $t \ge 0$.

Exercise 5.8. Give an example as an application of Theorem 5.3.2.

Exercise 5.9. Show that all trajectories of the system

$$\begin{pmatrix} x \\ y \end{pmatrix}' = \begin{pmatrix} 0 & 1 \\ -4 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

are periodic and determine their periods.

Copyright Elsevier 2022

Exercise 5.10. Describe the type of stability of the origin of each system and sketch the trajectories.
(a) $x' = x$, $y' = 2x + 2y$;
(b) $x' = -x$, $y' = x - y$;
(c) $x' = -x + 2y$, $y' = x - y$;
(d) $x' = -x + y$, $y' = 2x$;
(e) $x' = 2x - 8y$, $y' = x - 2y$;
(f) $x' = -3x + 2y$, $y' = -2x$.

Exercise 5.11. Consider the damped harmonic motion represented by the second-order differential equation

$$mx'' + ax' + kx = 0,$$

where m, a, and k are positive constants. By changing the equation into a system discuss the nature and stability of the origin in the following cases: $a = 0$; $a^2 - 4mk = 0$; $a^2 - 4mk < 0$; $a^2 - 4mk > 0$. Interpret the results physically.

Exercise 5.12. Decide whether each system is Hamiltonian or not; in the case it is, find the Hamiltonian function. Next, find the equilibrium solutions (if any) and classify their stabilities when possible.
(a) $x'' + x + x^3$;
(b) $\theta'' + \sin(\theta) = 0$;
(c) $x'' + x^2 - 1$;
(d) $x'' + x^2 + 1$.

Exercise 5.13. Decide whether each system is gradient or not; in the case it is, find the gradient function. Next, find the equilibrium solutions (if any) and classify their stabilities when possible.
(a) $x' = -4x(x - 1)(x - 2)$, $y' = -2y$;
(b) $x' = 1 - 2x$, $y' = -7 - 3y$;
(c) $x' = 3 - 2y^2x$, $y' = -2yx^2 - 4$;
(d) $x' = 4x^3 + 4xy$, $y' = 2x^2 + 2y - 1$.

Copyright Elsevier 2022

CHAPTER

Nonlinear systems

6

In general, nonlinear differential equations are important in applications, and their solutions are not known explicitly. Sometimes these equations may be linearized by an expansion process in which nonlinear terms are discarded. When nonlinear terms make vital contributions to the solution, this cannot be done, but sometimes it is enough to retain a few "small" ones. In this chapter, we look for different ways to obtain vital information regarding the behavior of solutions.

6.1 Bifurcations in scalar systems

In this section, we limit our discussion to the scalar differential equation

$$x' = f(x), \tag{6.1.1}$$

where $f : \mathbb{R} \to \mathbb{R}$ is continuously differentiable. We assume that x^* is an equilibrium solution of (6.1.1). We always assume that the equilibria are isolated, that is, if x^* is an equilibrium, then there is an open interval containing x^* but no other equilibria.

Fig. 6.1 shows a generic plot of $f(x)$ for $x^* = a, b, c$. The equilibrium solution a is an *attractor* (stable) since arrows to its left and right point toward it. The equilibrium solution b is a *repeller* (unstable) since the arrow to its left and the arrow to its right point away from it. Finally, the equilibrium solution c is *semi-stable* since the arrow to its left points toward it and the one to its right points away from it. In the case of the equilibrium solution a, we may say that it is *locally asymptotically stable* with respect to small perturbation or deviation from the equilibrium solution. To better illustrate the notion, consider the scenario of a population of foxes in a protected refuge that is in a locally asymptotically stable state a. Suppose a weather event caused a small number of the foxes to die. Local asymptotic stability means that the system will eventually return to the original state a. However, if the number of dead foxes is big, then the perturbation is not small, and in this event, there is no guarantee that the population of foxes will return to the original state a. In the case of the population return to state a for all perturbations, no matter how large, the state a is called *globally asymptotically stable*. Such topics will be considered in detail in Chapter 7.

Now we examine the dynamics of (6.1.1) in the neighborhood of its equilibrium solution x^*. If (6.1.1) is in an equilibrium state x^* and $\eta(t)$ represents a small pertur-

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00012-7

Copyright Elsevier 2022

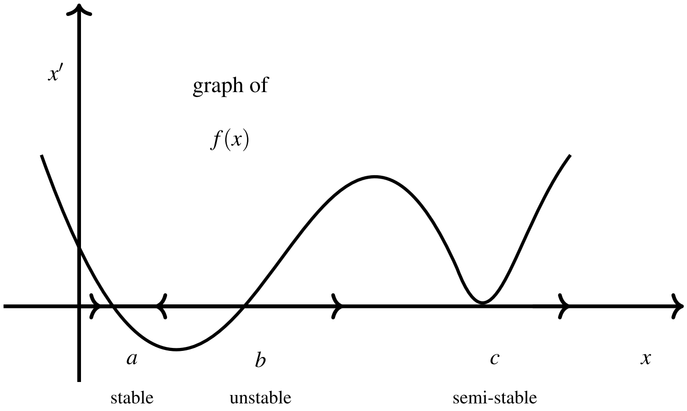

FIGURE 6.1

Generic phase line diagram.

bation from that state, then $x(t) = x^* + \eta(t)$. It follows that $x'(t) = \eta'(t)$. Thus using Taylor series expansion about x^*, we have

$$\begin{aligned} x'(t) = \eta'(t) = f(x^* + \eta) \\ &= f(x^*) + \frac{f'(x^*)}{1!}(x^* + \eta - x^*) + \frac{f''(x^*)}{2!}(x^* + \eta - x^*)^2 + \cdots \\ &= f'(x^*)\eta + \frac{f''(x^*)}{2!}\eta^2 + \cdots \\ &= f'(x^*)\eta + O(\eta^2) + \cdots . \end{aligned}$$

If $f'(x^*) \neq 0$, then the term $|f'(x^*)\eta| \gg |\frac{f''(x^*)}{2!}\eta^2|$. Thus we may neglect the term $O(\eta^2)$ and higher-order terms for that same reason. Then we arrive at the linearization of the system about the equilibrium state x^* given by

$$\eta'(t) = s\eta, \tag{6.1.2}$$

where $s = f'(x^*)$ is the slope of $f(x)$ at x^*. Eq. (6.1.2) has the solution

$$\eta(t) = ce^{st} \tag{6.1.3}$$

for some constant c. It is clear from (6.1.3) that if $s > 0$, then solutions grow exponentially, and the equilibrium solution x^* is unstable. On the other hand, if $s < 0$, then the solutions decay exponentially to zero, and the equilibrium solution x^* is asymptotically stable and hence is stable. If $s = 0$, then nothing can be said about the stability. Note that different stabilities may be obtained for different systems when

Copyright Elsevier 2022

$s = 0$. To see this, we consider the scalar differential equations

$$x' = x^2,\ x' = -x^2,\ x' = x^3,\ \text{ and }\ x' = -x^3.$$

All they share the equilibrium solution $x^* = 0$ and $s = f'(0) = 0$. Consider the first equation with $f(x) = x^2$. Then $f'(x) = 2x$, which is negative for $x < 0$ and positive for $x > 0$. Thus by the previous discussion the arrow to its left points toward $x^* = 0$, and the one to it right points away from it. It follows that $x^* = 0$ is semi-stable. By similar arguments we find that $x^* = 0$ is semi-stable for the second equation, unstable for the third equation, and stable for the fourth equation.

Example 6.1. If $x(t)$ represents a population at time t, $r > 0$ is the growth rate, and $K > 0$ is the carrying capacity, then the logistics model of the population growth is given by

$$x' = rx(1 - \frac{x}{K}). \tag{6.1.4}$$

Setting the right hand of (6.1.4) equal to zero, we arrive at two equilibrium solutions

$$x^* = 0,\ K.$$

Let $f(x) = rx(1 - \frac{x}{K})$. Then $f'(x) = r - \dfrac{2r}{K}x$. It follows from (6.1.2) that

$$s = f'(0) = r\ \text{ and }\ s = f'(K) = -r.$$

We conclude that $x^* = 0$ is unstable and $x^* = K$ is stable.

Although the dynamics of scalar differential equations is simple, since both solutions converge to a constant or become unbounded as $t \to \infty$, they can have some interesting behaviors if solutions depend on some embedded parameters. To be specific, when the parameters are varied and pass some critical values, the systems may experience some abrupt changes or undergo some qualitative changes. These qualitative changes are called *bifurcations*, and the parameter values at which the bifurcations occur are called *bifurcation points*. We are interested in scalar differential equations of the form

$$x' = f(x, \mu), \tag{6.1.5}$$

where f is continuous in both arguments, and $\mu \in \mathbb{R}$ is a parameter.

Thus the system is said to undergo a bifurcation as μ crosses some critical value μ_0 if, in some way, the nature of the solutions changes qualitatively between the regions $\mu < \mu_0$ and $\mu > \mu_0$.

Three most important one-dimensional equilibrium bifurcations are described locally by the following differential equations:

$$\begin{aligned} x' &= \mu - x^2, && \text{saddle-node;} \\ x' &= \mu x - x^2, && \text{transcritical; and} \\ x' &= \mu x - x^3, && \text{pitchfork.} \end{aligned}$$

Copyright Elsevier 2022

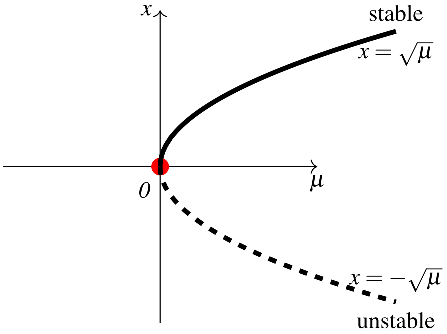

FIGURE 6.2

Bifurcation diagram determined by $x' = \mu - x^2$.

We will study each of these in more detail. We begin by considering *saddle node bifurcation*, which is the basic mechanism for creation and destruction of fixed points. As parameter varies, two fixed points move toward each other, collide, and mutually annihilate, that is, the saddle-node bifurcation results in fixed points being created or destroyed.

Example 6.2. Consider the scalar differential equation with parameter μ

$$x' = \mu - x^2. \tag{6.1.6}$$

Clearly, there are no equilibrium solutions for $\mu < 0$, and $x^* = \pm\sqrt{\mu}$ for $\mu > 0$. It is clear that $s = f'(\sqrt{\mu}) = -2\sqrt{\mu} < 0$ and $s = f'(-\sqrt{\mu}) = 2\sqrt{\mu} > 0$, which imply that the solid bold branch $x = \sqrt{\mu}$ is stable and the dashed branch $x = -\sqrt{\mu}$ is unstable. The bifurcation diagram is shown in Fig. 6.2, and since there is an exchange of stability at $\mu = 0$, we have a bifurcation at $\mu = 0$. This type of bifurcation is known by the names *saddle node bifurcation*, *fold bifurcation, turning point*, and *blue-sky bifurcation*. Note that at the bifurcation point $\mu = 0$, $s = f'(0) = 0$, and hence the linearization term disappears when equilibrium solutions coalesce.

Remark 6.1. In (6.1.6) of Example 6.2, if we change the term $-x^2$ to x^2, then

$$x' = \mu + x^2.$$

There are no equilibrium solutions for $\mu > 0$, and the curve $y = \mu + x^2$ does not intersect the x-axis. As $\mu \searrow 0$, the graph $y = \mu + x^2$ intersects the origin tangentially, and we have one equilibrium solution. As μ becomes negative, two equilibrium solutions appear at $x = \pm\sqrt{-\mu}$. Then, using the stability indicator s, we see that $x = -\sqrt{-\mu}$ is stable and $x = \sqrt{-\mu}$ is unstable. We conclude there is a *saddle node bifurcation* at $(0, 0)$ as indicated in the bifurcation diagram shown in Fig. 6.3.

Next, we discuss a class of bifurcations that occur as stability changes when going from one equilibrium solution to another. This type of bifurcation is called *transcritical bifurcation*.

Copyright Elsevier 2022

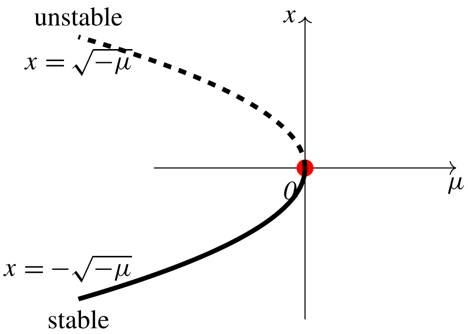

FIGURE 6.3

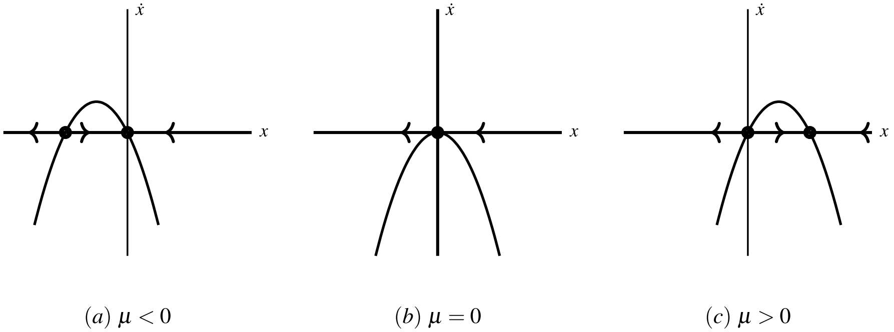
Bifurcation diagram determined by $x' = \mu + x^2$.



(a) $\mu < 0$ (b) $\mu = 0$ (c) $\mu > 0$

FIGURE 6.4

Phase portraits for different values of μ.

Example 6.3. To illustrate the idea, we consider the population growth model with carrying capacity

$$x' = \mu x - x^2.$$

The system has the equilibrium solutions $x^* = 0, \mu$. Using $s = f'(x^*)$, it follows that $x^* = 0$ is stable if $\mu < 0$ and unstable if $\mu > 0$. Similarly, $x^* = \mu$ is stable for $\mu > 0$ and unstable for $\mu < 0$. Fig. 6.4 shows the phase portraits for different values of μ. Also, Fig. 6.5 shows the bifurcation diagram. The stable branches are shown by bold solid lines, and the unstable branches are shown by dashed lines.

Next, we discuss a type of bifurcation called *pitchfork bifurcation*. The name comes from the shape of the bifurcation diagram that resembles a pitchfork. This type of bifurcation is common in problems that have a *symmetry*, for example, the buckling beam. In the case of pitchfork bifurcation the equilibrium solutions tend to appear and disappear symmetrically, creating a type of bifurcations that are different

Copyright Elsevier 2022

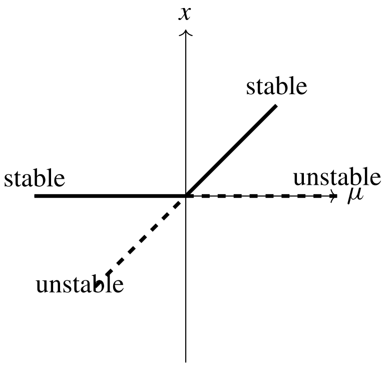


FIGURE 6.5

Bifurcation diagram that shows $(\mu, x) = (0, 0)$ is a transcritical bifurcation point.

from those that we have already discussed. Pitchfork bifurcations can come in one of two types, in the *supercritical bifurcation* and in the *subcritical bifurcation*.

Supercritical bifurcation is typified by equations of the form

$$x' = \mu x - x^3.$$

For $\mu < 0$, the origin is the only equilibrium solution, and it is stable. On the other hand, for $\mu > 0$, the origin is unstable, and the other two equilibrium solutions $\pm\sqrt{\mu}$ are stable.

Similarly, subcritical bifurcation is typified by equations of the form

$$x' = \mu x + x^3.$$

For $\mu < 0$, the origin is stable, and the other two equilibrium solutions $\pm\sqrt{\mu}$ are unstable. On the other hand, for $\mu > 0$, the origin is the only equilibrium solution, and it is unstable.

Example 6.4. We consider the scalar differential equation

$$x' = \mu x - x^3.$$

It is clear that $x^* = 0$ is an equilibrium solution regardless of the sign of μ and $x^* = \pm\sqrt{\mu}$ only if $\mu \geq 0$. Note that for any fixed value of μ, the function $y = \mu x - x^3$ is an odd function in x. Hence critical points will appear and disappear symmetrically with respect to the origin, or the system has the left–right symmetry. Using $s = f'(x^*) = \mu - 3(x^*)^2$, it follows $x^* = 0$ is stable for $\mu \leq 0$ and unstable for $\mu \geq 0$. In addition, $s = f(\pm\sqrt{\mu}) = -2\mu < 0$ implies that the equilibrium solutions $\pm\sqrt{\mu}$ are stable. The bifurcation diagram is displayed in Fig. 6.6.

Fig. 6.6 indicates that two stable equilibrium solutions or branches are created at the bifurcation point $(0, 0)$ and still exist after the bifurcation. A similar remark can be drawn regarding the subcritical bifurcation.

Copyright Elsevier 2022

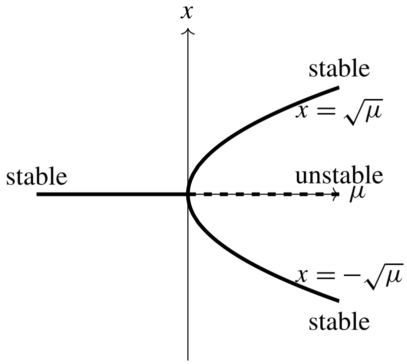

FIGURE 6.6

Bifurcation diagram determined for $x' = \mu x - x^3$; supercritical bifurcation at $(0, 0)$.

The next theorem is the scalar version of the *implicit function theorem*.

Theorem 6.1.1. *For scalar system* (6.1.5)*, suppose that* $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *with continuous first partial derivatives. Suppose* x_0 *is an equilibrium solution at* μ_0*, meaning that* $f(x_0, \mu_0) = 0$*. Assume that*

$$f(x_0, \mu_0) = 0, \quad \frac{\partial f}{\partial x}(x_0, \mu_0) \neq 0.$$

Then there exist $\delta, \varepsilon > 0$ *and a* C^1*-function*

$$\tilde{x} : (\mu_0 - \varepsilon, \mu_0 + \varepsilon) \to \mathbb{R}$$

such that $x = \tilde{x}$ *is the unique solution of*

$$f(x, \mu) = 0$$

with $|x - x_0| < \delta$ *and* $|\mu - \mu_0| < \varepsilon$*.*

For bifurcation theory, we have the following important result.

Corollary 6.1. *Suppose that* $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *has continuous first partial derivatives. Suppose* x_0 *is an equilibrium solution at* μ_0 *for* (6.1.5)*. Then a necessary condition for a solution* (x_0, μ_0) *of* (6.1.5) *to be a bifurcation point of equilibria is that*

$$\frac{\partial f}{\partial x}(x_0, \mu_0) = 0. \tag{6.1.7}$$

The next theorem provides necessary conditions that guarantee the different types of bifurcation points we have discussed so far.

Copyright Elsevier 2022

Theorem 6.1.2. *Suppose that* $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *is continuous in both arguments and has continuous first and second partial derivatives. Suppose that at* (x_0, μ_0)*,* f *satisfies the necessary bifurcation conditions*

$$f(x_0, \mu_0) = 0, \quad \frac{\partial f}{\partial x}(x_0, \mu_0) = 0.$$

(1) If

$$\frac{\partial f}{\partial \mu}(x_0, \mu_0) \neq 0, \quad \frac{\partial^2 f}{\partial x^2}(x_0, \mu_0) \neq 0,$$

then a saddle node bifurcation occurs at (x_0, μ_0).
(2) If

$$\frac{\partial f}{\partial \mu}(x_0, \mu_0) = 0, \quad \frac{\partial^2 f}{\partial x \partial \mu}(x_0, \mu_0) \neq 0, \quad \frac{\partial^2 f}{\partial x^2}(x_0, \mu_0) \neq 0,$$

then a transcritical bifurcation occurs at (x_0, μ_0).
(3) If

$$\frac{\partial f}{\partial \mu}(x_0, \mu_0) = 0, \quad \frac{\partial^2 f}{\partial x^2}(x_0, \mu_0) = 0,$$

$$\frac{\partial^2 f}{\partial x \partial \mu}(x_0, \mu_0) \neq 0, \quad \frac{\partial^3 f}{\partial x^3}(x_0, \mu_0) \neq 0,$$

then a pitchfork bifurcation occurs at (x_0, μ_0)*. In addition,*
(i) if $\frac{\partial^3 f}{\partial x^3}(x_0, \mu_0) < 0$*, then there is a supercritical bifurcation at* (x_0, μ_0)*, and*
(ii) if $\frac{\partial^3 f}{\partial x^3}(x_0, \mu_0) > 0$*, then there is a subcritical bifurcation at* (x_0, μ_0).

Example 6.5. We consider the scalar system

$$x' = \mu x - e^x.$$

Then its bifurcation points must satisfy

$$\mu x - e^x = 0.$$

Plotting the graphs $y = \mu x$ and $y = e^x$, we see that the line $y = x$ is tangent to the curve at $(x, y) = (1, e)$. In other words, if we set $f(x, \mu) = \mu x - e^x$, then $f(1, e) = 0$. This says that $x_0 = 1$ is an equilibrium solution for $\mu = e$. Moreover, $\frac{\partial f}{\partial x}(1, e) = 0$. In addition, $\frac{\partial f}{\partial \mu}(x_0, \mu_0) = 1 \neq 0$, and $\frac{\partial^2 f}{\partial x^2}(x_0, \mu_0) = -e \neq 0$, and so by item 1 of Theorem 6.1.2 there is a saddle node bifurcation at $(1, e)$.

Remark 6.2. Suppose bifurcation for (6.1.5) occurs at (x_0, μ_0). We may translate to the origin $(0, 0)$ by the change of variables $x \to x - x_0$, $\mu \to \mu - \mu_0$. Moreover, if

Copyright Elsevier 2022

$x = \tilde{x}(\mu)$ is a solution branch, then $x \to x - \tilde{x}(\mu)$ maps the branch to $x = 0$. Suppose we have a saddle node bifurcation. For $(0, 0)$ to be a bifurcation point, we must have

$$f(x_0, \mu_0) = 0, \quad \frac{\partial f}{\partial x}(x_0, \mu_0) = 0.$$

Further, suppose that

$$\frac{\partial f}{\partial \mu}(0, 0) = a \neq 0, \quad \frac{\partial^2 f}{\partial x^2}(0, 0) = b \neq 0.$$

Then if in the Taylor expansion of $f(x, \mu)$, we neglect quadratic terms in μ and cubic terms in x, then near $(x, \mu) = (0, 0)$, we obtain

$$\begin{aligned} f(x, \mu) &= \mu \frac{\partial f}{\partial \mu}(0, 0) + x \frac{\partial f}{\partial x}(0, 0) + \frac{x^2}{2} \frac{\partial^2 f}{\partial x^2}(0, 0) + \cdots \\ &= a\mu + bx^2 + \cdots . \end{aligned} \tag{6.1.8}$$

The form $a\mu + bx^2$ in (6.1.8) is called a *normal form* or *representative* for scalar saddle node bifurcations. Thus the original system may be approximated near the origin by

$$x' = a\mu + bx^2.$$

The signs of a and b determine the type of bifurcations and the shape of the bifurcation diagrams as shown in Example 6.2 and Remark 6.1.

We end the section with the following application.

Example 6.6. (*Bucking of a rod*) The potential energy of the system of two rigid rods of length L connected by a torsional spring with spring constant k is given by the function

$$R(x) = \frac{1}{2} k x^2 + 2\lambda L \big(\cos(x) - 1\big),$$

where λ is the strength of compressive force, and x is the angle of the rod to the horizontal axis. The term $\frac{1}{2}kx^2$ is the energy required to compress the spring by the angle $2x$, and $2\lambda L\big(\cos(x) - 1\big)$ is the work done on the system by the external force. Equilibrium solutions satisfy $R'(x) = 0$ or

$$x - \mu \sin(x) = 0, \quad \mu = \frac{2\lambda L}{k},$$

where μ is a dimensionless force parameter. The above equation has the unbuckled equilibrium solution $x = 0$. Set

$$f(x, \mu) = R'(x) = \mu \sin(x) - x.$$

Copyright Elsevier 2022

Then the necessary conditions for an equilibrium bifurcation are

$$\frac{\partial f}{\partial x} = \mu - 1 = 0,$$

which occurs at $\mu = 1$. By finding the Taylor series of f at $(0, 1)$ we arrive at

$$f(x, \mu) = (\mu - 1)x - \frac{1}{6}x^3 + \cdots .$$

We can see from Example 6.4 or verifying the conditions of item 3 of Theorem 6.1.2 that there is a pitchfork bifurcation at $(x, \mu) = (0, 1)$. The bifurcation equilibria near this point are given for $0 < \mu - 1 \ll 1$ by

$$x = \sqrt{6(\mu - 1)} + \cdots .$$

This can also be seen by plotting the graphs $y = x$ and $y = \mu \sin(x)$.

This simple one-dimensional problem is an illustration for the buckling of an elastic beam, one of the first bifurcation problems which was originally studied by Euler in 1757.

For the rest of this chapter, if $x = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$, then $|x| = \sum_{i=1}^{n} |x_i|$, and for an $n \times n$ matrix, $A = a_{ij}$, $|A| = \sum_{i,j=1}^{n} |a_{ij}|$.

6.2 Stability of systems by linearization

Consider the general system of ordinary differential equations

$$\begin{aligned} x_1' &= f_1(x_1, \ldots, x_n), \\ x_2' &= f_2(x_1, \ldots, x_n), \\ &\vdots \\ x_n' &= f_n(x_1, \ldots, x_n). \end{aligned}$$

Using the vector notations

$$x = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$$

Copyright Elsevier 2022

and

$$f(x) = \begin{pmatrix} f_1(x) \\ f_2(x) \\ \vdots \\ f_n(x) \end{pmatrix},$$

the above system can be written in the vector form

$$x' = f(x), \tag{6.2.1}$$

where $f : \mathbb{R}^n \to \mathbb{R}^n$ with continuously differentiable components. We assume that the vector $x^* = (x_1^*, x_2^*, \dots, x_n^*)$ is a fixed point of (6.2.1).

Define the linear part of f at x^* by $J(x^*)$, where

$$J(x^*) := \begin{pmatrix} \frac{\partial f_1}{\partial x_1}(x^*) & \frac{\partial f_1}{\partial x_2}(x^*) & \cdots & \frac{\partial f_1}{\partial x_n}(x^*) \\ \frac{\partial f_2}{\partial x_1}(x^*) & \frac{\partial f_2}{\partial x_2}(x^*) & \cdots & \frac{\partial f_2}{\partial x_n}(x^*) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1}(x^*) & \frac{\partial f_n}{\partial x_2}(x^*) & \cdots & \frac{\partial f_n}{\partial x_n}(x^*) \end{pmatrix}, \tag{6.2.2}$$

which is called the *Jacobian* of f at x^*. Since $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$, Taylor's theorem for functions of several variables says that

$$f(x) = J(x^*)(x - x^*) + g(x) \ \ \text{(we have used } f(x^*) = 0\text{)}, \tag{6.2.3}$$

where g is a function that is small in the neighborhood of x^* in the sense that

$$\lim_{x \to x^*} \frac{|g(x)|}{|x - x^*|} = 0. \tag{6.2.4}$$

Note that since $f(x^*) = 0$, (6.2.3) implies that $g(x^*) = 0$. Our hope is to prove that if $Re(\rho(J(x^*))) < 0$ or the origin for

$$y' = J(x^*)y$$

is asymptotically stable, then the equilibrium point x^* of (6.2.1) is asymptotically stable. Note that by introducing the transformation $y = x - x^*$ we may assume without loss of generality that the fixed point is at the origin. Thus we have the following general theorem.

Theorem 6.2.1. *Assume that* $Re(\rho(A)) < 0$ *where* A *is an* $n \times n$ *constant matrix. Let* U *be an open set of* $\mathbb{R} \times \mathbb{R}^n$ *that contains* $[0, \infty) \times B_r(0)$, *where* $B_r(0) = \{x \in \mathbb{R}^n : |x - 0| \le r\}$ *for positive constant* r. *Assume that* $g : U \to \mathbb{R}^n$ *is continuous in both arguments and Lipschitz in the second argument such that*

$$\lim_{x \to 0} \frac{|g(t, x)|}{|x|} = 0 \ \textit{uniformly for} \ \ t \in [0, \infty) \tag{6.2.5}$$

Copyright Elsevier 2022

with $g(t,0)=0$. *Then the origin for the perturbed nonlinear system*

$$x' = Ax + g(t,x) \tag{6.2.6}$$

is asymptotically stable.

Proof. Since $Re(\rho(A)) < 0$, we can find constants $K > 0$ and $\xi < 0$ such that

$$||e^{At}|| \le Ke^{\xi t}, \ \ t > 0.$$

Let $x(t)$ be a solution of (6.2.6) on some interval (a,b) containing 0 with $x(0)=x_0$. Then the variation of parameters formula (3.3.6) yields

$$x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^{t} e^{A(t-s)}g(s,x(s))ds. \tag{6.2.7}$$

Taking the appropriate norms of both sides of (6.2.7) and estimating give, for $t \ge 0$,

$$|x(t)| = K|x_0|e^{\xi t} + \int_0^t Ke^{\xi(t-s)}|g(s,x(s))|ds, \ \ t \in [0,b).$$

Multiplying both sides by $e^{-\xi t}$, we arrive at the expression

$$|x(t)|e^{-\xi t} = K|x_0| + \int_0^t Ke^{-\xi s}|g(s,x(s))|ds, \ \ t \in [0,b).$$

Chose $\eta > 0$ such that $\eta K < -\xi$. Thus by (6.2.5) we have that

$$|g(t,x)| \le \eta|x| \ \text{ for } (t,x) \in [0,\infty) \times \bar{B}_r(0).$$

Set $\delta^* = \delta/(2K+1) < \delta$. Suppose that $|x_0| < \delta^*$, and let (a,b) be the maximal interval of existence with $x(0)=x_0$.

Let $[0,c] \subseteq (a,b)$ be an interval such that $|x(t)| \le \delta$ for all $t \in [0,c]$. This is possible due to the continuity of x. By the above inequality of g we have that

$$|g(t,x)| \le \eta|x| \ \text{ for } t \in [0,c].$$

Then we have

$$|x(t)|e^{-\xi t} = K|x_0| + \int_0^t Ke^{-\xi s}\eta|x(s)|ds, \ \ t \in [0,c].$$

Use Gronwall's inequality and then evaluate the integral to get

$$\begin{aligned} |x(t)|e^{-\xi t} &\le K^2|x_0|\eta\frac{1}{K\eta}[e^{K\eta t}-1] \\ &= K|x_0|e^{K\eta t}. \end{aligned}$$

Copyright Elsevier 2022

Since $|x_0| < \delta^*$, $K|x_0| < \delta$, and so $|x(t)|e^{-\xi t} \le \delta e^{K\eta t}$. It follows that

$$|x(t)| \le \delta e^{(\xi + K\eta)t}, \quad t \in [0, c], \tag{6.2.8}$$

where $\xi + K\eta < 0$.

Of course, we only showed that inequality (6.2.8) holds for $|x(t)| \le \delta$ on $[0, c]$. It is left as an exercise to show that the inequality holds on $[0, \infty)$. This completes the proof. □

Remark 6.3. (1) If the origin is stable for the linear system $x' = Ax$ but not asymptotically stable, then it is not necessary that the origin is stable for the nonlinear system (6.2.6).
(2) If the origin is unstable for the linear system $x' = Ax$, then it is unstable for the nonlinear system (6.2.6).

Remark 6.4. Let $D \subset \mathbb{R}^n$ containing the origin. Consider the autonomous system

$$x' = f(x), \tag{6.2.9}$$

where $f : D \to \mathbb{R}^n$ with continuously differentiable components and $f(0) = 0$. Let $A = J(0)$ be the Jacobian matrix of f at $x = 0$. Rewrite (6.2.9) as

$$x' = Ax + g(x), \tag{6.2.10}$$

where $g(x) = f(x) - Ax$. The differentiability of f implies $g(x) = o(|x|)$ as $x \to \infty$. Therefore $g(x)$ satisfies condition (6.2.5).

The next theorem provides results concerning the UAS of the zero solution. Its proof is left as an exercise.

Theorem 6.2.2. *Assume that $Re(\rho(A)) < 0$, where A is an $n \times n$ constant matrix (or the zero solution of the linear part is AS). Assume that a continuous function $g(t, x)$ satisfies Lipschitz or local Lipschitz condition in the second argument for $x \in D$. Suppose that*

$$\lim_{x \to 0} \frac{|g(t, x)|}{|x|} = 0 \text{ uniformly for } t \in [0, \infty) \tag{6.2.11}$$

with $g(t, 0) = 0$. Then the origin for the perturbed nonlinear system

$$x' = Ax + g(t, x)$$

is uniformly asymptotically stable.

We have the following example.

Example 6.7. The zero solution of the nonlinear non-autonomous system

$$x' = -x + \frac{t}{t+1}x^2$$

Copyright Elsevier 2022

is UAS. It is obvious that the zero solution of the linear part $x' = -x$ is AS. We must show that condition (6.2.11) holds. Let $g(t,x) = \frac{t}{t+1}x^2$. Then g is continuous, and for any open subset $D = (\alpha, \beta) \subset \mathbb{R}$ containing the origin, we have

$$|g(t,x) - g(t,y)| \le 2\beta|x-y| \text{ for all } \ (t,x),(t,y) \in [0,\infty) \times D.$$

Moreover,

$$\lim_{x\to 0} \frac{|g(t,x)|}{|x|} \le \lim_{x\to 0} \frac{x^2}{|x|} = 0 \text{ uniformly for } t \in [0,\infty).$$

Thus by Theorem 6.2.2 the zero solution is UAS.

The next example shows the needs for a different approach when the eigenvalues of the matrix A fail to have negative real parts.

Example 6.8. Consider the planar autonomous system

$$x' = -y + x\sqrt{x^2+y^2}, \ \ y' = x + y\sqrt{x^2+y^2}.$$

It is clear that (0, 0) is the only equilibrium point. We rewrite the system in the form

$$\begin{pmatrix} x \\ y \end{pmatrix}' = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} x\sqrt{x^2+y^2} \\ y\sqrt{x^2+y^2} \end{pmatrix}.$$

The eigenvalues of

$$A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

are $\pm i$. Thus Theorem 6.2.1 does not apply. Instead, we use the polar coordinates. Namely,

$$x = r\cos(\theta), \ y = r\sin(\theta), \ \text{ where } r^2 = x^2 + y^2,$$

and $r = r(t)$ and $\theta = \theta(t) = \tan^{-1}(\frac{y}{x})$. Thus

$$\frac{d}{dt}(x^2+y^2) = \frac{d}{dt}r^2$$

or

$$xx' + yy' = rr'.$$

A substitution of x' and y' yields

$$\begin{aligned} rr' &= x(-y + x\sqrt{x^2+y^2}) + y(x + y\sqrt{x^2+y^2}) \\ &= (x^2+y^2)\sqrt{x^2+y^2} \\ &= r^2 r. \end{aligned}$$

Copyright Elsevier 2022

Thus we have the first-order differential equation

$$r' = r^2, \tag{6.2.12}$$

which implies that the function r is increasing. Thus trajectories are spiraling away from the origin, and hence the origin is unstable. In addition,

$$\theta' = \frac{xy' - x'y}{x^2 + y^2} = 1.$$

Choosing $\theta(0) = 0$, we have $\theta(t) = t$, which indicates trajectories spiral away from the origin counterclockwise. Note that using separation of variables, (6.2.12) can be easily solved to find $r(t) = \frac{1}{k-t}$ for some suitable constant k. Notice that $r(t) \to \infty$ as $t \to k^-$.

Example 6.9. In Example 3.5, we considered a pendulum with friction and arrived at the planar autonomous system

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= -\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2. \end{aligned} \tag{6.2.13}$$

It is clear that system (6.2.13) has infinitely many equilibrium points $(n\pi, 0)$, $n = 0, 1, \dots,$ which correspond to vertical positions with zero velocity. We will only analyze two equilibrium points $(0, 0)$ and $(\pi, 0)$. For the equilibrium point $(0, 0)$, we write system (6.2.13) in the form

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}' = \begin{pmatrix} 0 & 1 \\ -\frac{g}{L} & -\frac{b}{m} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \frac{g}{L} \begin{pmatrix} 0 \\ x_1 - \sin(x_1) \end{pmatrix}.$$

The linear part has the eigenvalues

$$\lambda_1 = -\frac{b}{2m} + \frac{1}{2}\Big(\frac{b^2}{m^2} - 4\frac{g}{L}\Big)^{1/2}$$

and

$$\lambda_1 = -\frac{b}{2m} - \frac{1}{2}\Big(\frac{b^2}{m^2} - 4\frac{g}{L}\Big)^{1/2}.$$

If $\frac{b^2}{m^2} - 4\frac{g}{L} < 0$ (when damping is weak), then the eigenvalues are complex with negative real parts, and the origin is a stable spiral. If $\frac{b^2}{m^2} - 4\frac{g}{L} \geq 0$ (when the damping is strong), that is,

$$\frac{b^2}{m^2} > 4\frac{g}{L},$$

Copyright Elsevier 2022

we have that $\lambda_2 \leq \lambda_1 < 0$, and hence the equilibrium solution $(0,0)$ for system (6.2.13) is asymptotically stable by Theorem 6.2.1.

The physical and geometrical interpretation for $(x_1, x_2') = (0,0)$ being a stable spiral corresponds to the pendulum hanging vertically downward ($x_1 = 0$) with zero velocity ($x_2' = 0$), and thus, when the damping is weak, a perturbation will cause the pendulum to spiral and approach the vertically downward position.

For the equilibrium point $(\pi, 0)$, we use the transformation

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} \pi \\ 0 \end{pmatrix}$$

in (6.2.13), obtaining

$$\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \begin{pmatrix} y_2 \\ \frac{g}{L}\sin(y_1) - \frac{b}{m}y_2 \end{pmatrix}.$$

To examine this system near $(0,0)$, we write the above new nonlinear system in y in the form

$$\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \begin{pmatrix} 0 & 1 \\ \frac{g}{L} & -\frac{b}{m} \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} - \frac{g}{L} \begin{pmatrix} 0 \\ y_1 - \sin(y_1) \end{pmatrix}.$$

The linear parts have the eigenvalues

$$\lambda_1 = -\frac{b}{2m} + \Big(\frac{b^2}{m^2} + 4\frac{g}{L}\Big)^{1/2},$$
$$\lambda_1 = -\frac{b}{2m} - \Big(\frac{b^2}{m^2} + 4\frac{g}{L}\Big)^{1/2}.$$

It is clear that $\lambda_2 < 0 < \lambda_1$ and the equilibrium point $(0,0)$ and hence $(\pi, 0)$ are unstable.

Note that we could calculate the Jacobian given by (6.2.2) at $(\pi, 0)$ and obtain

$$J((\pi,0)) = \begin{pmatrix} 0 & 1 \\ \frac{g}{L} & -\frac{b}{m} \end{pmatrix},$$

instead of using transformation.

If we compute $J((\pm n\pi, 0))$, then we will see that $(\pm n\pi, 0)$ are stable for $n = 2, 4, \ldots$ and unstable for $n = 1, 3, \ldots$.

Example 6.10. (*Lotka–Volterra predator–prey model*) In Example 4.1 we considered the Lotka–Volterra system

$$\begin{aligned} \frac{dx}{dt} &= ax - bxy, \\ \frac{dy}{dt} &= -cy + dxy \end{aligned} \tag{6.2.14}$$

Copyright Elsevier 2022

and found that the equilibrium solutions are

$$x_1^* = (0, 0) \text{ and } x_2^* = (c/d, a/b).$$

The first equilibrium solution x_1^* effectively represents the extinction of both species. If both populations are at 0, then they will continue to be so indefinitely. The second equilibrium solution x_2^* represents a fixed point at which both populations sustain their current, non-zero numbers, and do so indefinitely. The levels of population at which this equilibrium is achieved depend on the chosen values of the parameters a, b, c, and d. Now we will further discuss the stability of both equilibrium solutions x_1^* and x_2^* and hope that x_1^* is unstable and x_2^* is stable. The Jacobian matrix is

$$J(x, y) = \begin{pmatrix} a - by & -bx \\ dy & -c + dx \end{pmatrix}.$$

For $x_1^* = (0, 0)$, we have

$$J(0, 0) = \begin{pmatrix} a & 0 \\ 0 & -c \end{pmatrix}$$

with eigenvalues $a > 0$ and $-c < 0$. Thus the equilibrium point $(0, 0)$ is a saddle and hence unstable.

For $x_2^* = (c/d, a/b)$,

$$J(c/d, a/b) = \begin{pmatrix} 0 & -\frac{bc}{d} \\ \frac{da}{b} & 0 \end{pmatrix},$$

which has purely imaginary eigenvalues. Hence linearization is inconclusive. Note that the use of polar coordinates will not work here in the sense that it is hard, if not impossible, to obtain any information from it. We look at the vector fields surrounding the equilibrium point by dividing the region of interest into four quadrants as depicted in Fig. 6.1. We do so by drawing vertical and horizontal lines through the equilibrium point $(c/d, a/b)$. Those lines are called the x and y *nullclines*. We begin by writing system (6.2.14) in the form

$$x' = x(a - by), \quad y' = y(-c + dx). \tag{6.2.15}$$

The x nullclines for system (6.2.15) where $x' = 0$ are $x = 0$ and $y = \frac{a}{b}$. Trajectories cross these two lines vertically. Similarly, trajectories cross the y nullclines where $y' = 0$ horizontally. We see that the equilibria are the intersections of the x and y nullclines. On the ray to the left of the equilibrium and below the line $y = a/b$, we have $x < \frac{c}{d}$ and $y = \frac{a}{b}$. We know that the vector field is vertical, and so we only need to check the sign of y'. From (6.2.15) we have

$$y' = y(-c + dx) = \frac{a}{b}(-c + dx) < \frac{a}{b}(-c + d\frac{c}{d}) = 0.$$

Copyright Elsevier 2022

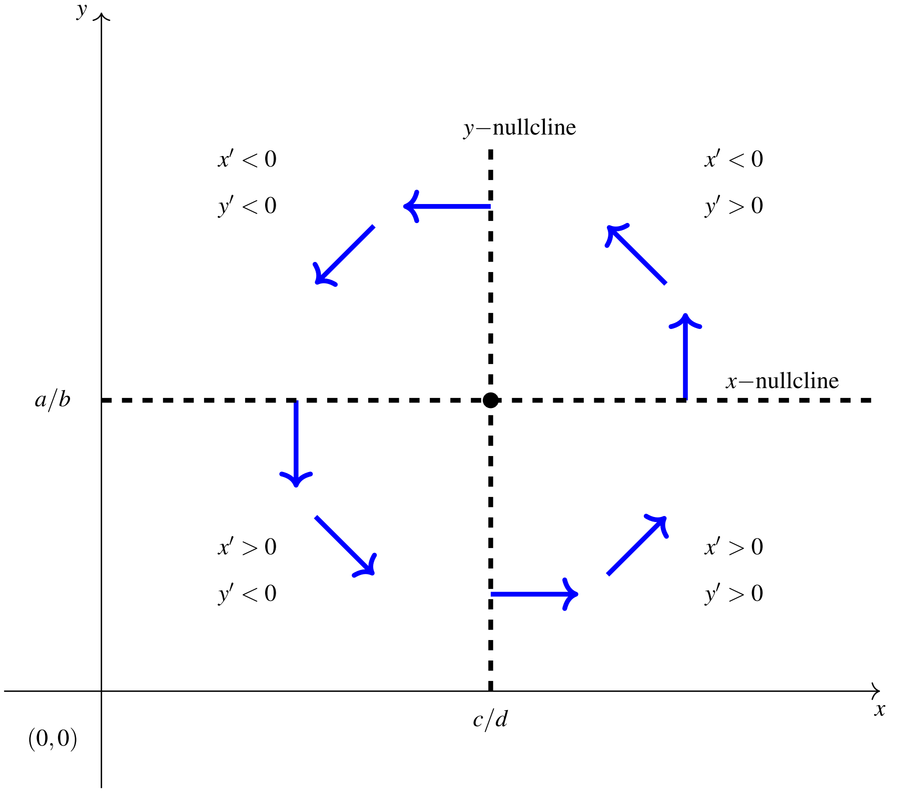

FIGURE 6.7

Nullclines and vector field.

Thus in that region, we have that $x' > 0$ and $y' < 0$. Similarly, if we consider the region to the left of the vertical line $x = \frac{c}{d}$ and above the horizontal line $y = c/d$, then we have that $x = \frac{c}{d}$ and $y > \frac{a}{b}$. Again, the vector field is horizontal, and we only need to check the sign of x'. From (6.2.15) we have

$$x' = x(a - by) < \frac{c}{d}(a - b\frac{a}{b}) = 0.$$

Thus in that particular region, we have $x' < 0$, $y' < 0$. This task can be easily performed for the other two regions. The complete vector field around the equilibrium is displayed in Fig. 6.7. To obtain the trajectories, we write the system in the form

$$\frac{dy}{dx} = \frac{y(-c + d\,x)}{x(a - by)}.$$

Copyright Elsevier 2022

After rearranging the terms, we get

$$\frac{(a - by)}{y} dy = \frac{(-c + d\,x)}{x} dx.$$

Simplifying and then integrating both sides yield

$$a\mathrm{Ln}(y) - by = -c\mathrm{Ln}(x) + d\,x + K \text{ for some constant } K.$$

Exponentiating both sides gives

$$y^a e^{-by} = x^{-c} e^{d\,x} e^K.$$

We consider the y nullcline where the value of x is fixed at c/d. We choose a specific trajectory by assigning a fixed value for K. Then the right side of the above relation is positive β, so that

$$y^a = \beta e^{by}. \tag{6.2.16}$$

The left and right sides of (6.2.16) are the power and exponential functions, respectively. Therefore if we plot them on the same graph, then there can be at most two crossings, or Eq. (6.2.16) can have at most two solutions for y. Thus along the y nullcline, there can be at most two crossings. That means that an orbit or trajectory cannot spiral into or out from an equilibrium point. Otherwise, many values of y would be required, which is not the case here. This determines that the equilibrium point $(c/d, a/b)$ is encircled with periodic trajectories, and hence it is stable. Note that the periodic trajectories encircling the equilibrium point $(c/d, a/b)$ indicate that a small perturbation from the equilibrium solution puts the populations on a periodic orbit that stays near the equilibrium and the system never returns to equilibrium. A phase diagram is shown in Fig. 6.8.

6.3 An SIR epidemic model

Here is the perfect place to apply what we have studied so far to an SIR model, where

$S = S(t)$ is the number of susceptible individuals (not yet having the disease but capable of getting it)
$I = I(t)$ is the number of infected individuals, and
$R = R(t)$ is the number of recovered or removed individuals.

We assume that the total population is constant and everyone is susceptible. Then

$$S + I + R = N \text{ (constant)},$$

that is,

$$S + I + R = 1 \text{ (by normalization)}.$$

Copyright Elsevier 2022

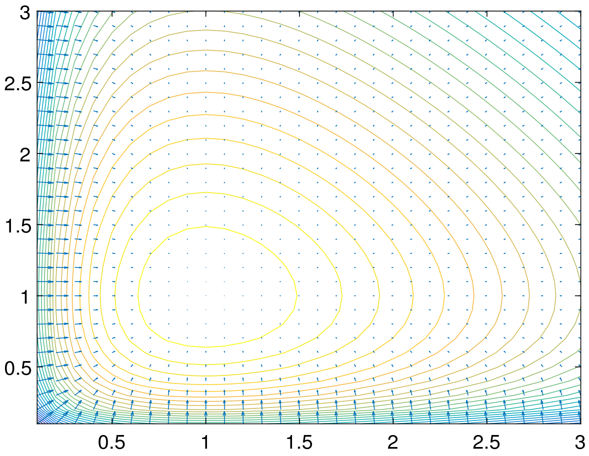

FIGURE 6.8

Prey–predator dynamics as described by the level curves. The arrows describe the velocity and direction of solutions. We chose $a = b = c = d = 1$.

Let

$\mu =$ birth rate $=$ death rate (because the number of people is constant),
$\gamma =$ removal rate, and
$\lambda =$ infection rate.

We assume that all newborns are susceptible and arrive at the epidemic model

$$\begin{cases} S'(t) = (S + I + R)\mu - \mu S - (SI)\lambda, \\ I'(t) = -\mu I - \gamma I + \lambda SI, \\ R'(t) = -\mu R + \gamma I. \end{cases}$$

We have $(S + I + R)\mu = \mu$, since the population is constant and normalized at 1. The term of μS represents the death of susceptible, and the negative implies loss or removal from being susceptible. On the other hand, the term $(SI)\lambda$ denotes those who got infected, and the minus represents that they are infected and not susceptible anymore. Similarly, the term μI represents those who die from the infection, and the minus indicates a loss for those who are infected already. In addition, the term γI indicates those who are removed from the population due to beating the epidemic or got vaccinated. Finally, the term μR denotes those who are removed due to death. Keep in mind that *minus* means loss from a certain class for S, I, and R, and *plus* implies gain for the same classes. Thus by only analyzing $S \geq 0$ and $I \geq 0$ we arrive at the 2×2-planar system

$$\begin{cases} S' = \mu - \mu S - \lambda SI, \\ I' = -(\mu + \gamma)I + \lambda SI. \end{cases} \tag{6.3.1}$$

Copyright Elsevier 2022

Note that system (6.3.1) is nonlinear and $(0,0)$ is not an equilibrium solution. Also, the system is valid in the region $0 \le S + I \le 1$ since we are neglecting R. It is important to note that the system does not allow those who recover from the epidemic to become susceptible again. Suppose $S(t_0) = S_0$ and $I(t_0) = I_0$. Since the right side of (6.3.1) is continuous with continuous first partial derivatives, we know that the solutions $S(t, t_0, S_0)$ and $I(t, t_0, I_0)$ exist and are unique. Moreover, $S(t, t_0, S_0)$ and $I(t, t_0, S_0)$ are continuous and differentiable with respect to all variables. Next, we examine how big the interval on which the solutions exist. Due to our constraints, we are interested in the triangular region of existence

$$T = \{(S, I) : S \ge 0, I \ge 0,\ S + I < 1\}.$$

Along $S = 0$, we have $S' = \mu > 0$, $0 \le I < 1$, and $I' = -(\mu + \gamma)I < 0$ if $I > 0$. Moreover,

$$\frac{dI}{dS} = \frac{I'}{S'} < 0.$$

Thus any trajectory that starts on the I-axis moves downward inside T in the positive direction of S.

Now, along $I = 0$, we have $S' = \mu(\mu - S) > 0$, $0 \le I < 1$, and $I' = 0$. Thus any trajectory that starts on the S-axis moves toward the point $(1, 0)$, at which the line $S + I = 1$ intersects the S-axis. Note that $(1, 0)$ is an equilibrium solution.

Along the line $S + I = 1$, we have

$$(S + I)' = S' + I' = \mu - \mu(S + I) - \gamma I,$$

and since $S + I = 1$, this expression reduces to

$$(S + I)' = -\gamma I < 0.$$

This tells us that any trajectory starting at the line $S + I = 1$ moves to the left of the line toward the inside of the triangle T. We conclude that the triangular region T is positively invariant, that is, if $(S_0, I_0) \in T$, then $S(t, t_0, S_0),\ I(t, t_0, I_0) \in T$ for all $t \ge t_0$. Thus the maximum interval of existence for solutions in T is $[t_0, \infty)$. From now on we refer to the triangular region T as the feasible region. Next, we search for the equilibrium solutions (S^*, I^*) in the feasible region. To do so, we must solve for S and I by setting the right sides of (6.3.1) to zero, that is, $S' = 0$, and $I' = 0$:

$$\mu - \mu S - \lambda SI = 0, \text{ and } -(\mu + \gamma)I + \lambda SI = 0.$$

From the second equation we obtain

$$\big(-\mu - \gamma + \lambda S\big)I = 0.$$

Thus if $I \ne 0$, then we arrive at

$$S^* = \frac{\mu + \gamma}{\lambda}.$$

Copyright Elsevier 2022

Clearly, $S^* \geq 0$, and in order for S^* to be in the feasible region, we must have

$$\mu + \gamma < \lambda.$$

Substituting $S^* = \frac{\mu+\gamma}{\lambda}$ into the equation $\mu - \mu S^* - \lambda S^* I^* = 0$, we arrive at

$$I^* = \frac{\mu}{\mu+\gamma} - \frac{\mu}{\lambda}.$$

It is clear $I^* > 0$, since

$$I^* = \frac{\mu}{\mu+\gamma} - \frac{\mu}{\lambda} > \frac{\mu}{\lambda} - \frac{\mu}{\lambda} = 0.$$

Next, we show that (S^*, I^*), belongs to the feasible region:

$$\begin{aligned} 0 < S^* + I^* &= \frac{\mu+\gamma}{\lambda} + \frac{\mu}{\mu+\gamma} - \frac{\mu}{\lambda} \\ &= \frac{\gamma}{\lambda} + \frac{\mu}{\mu+\gamma} \\ &< \frac{\gamma}{\mu+\gamma} + \frac{\mu}{\mu+\gamma} \\ &= 1. \end{aligned}$$

Thus the two equilibrium solutions $(1, 0)$ and (S^*, I^*) belong to the feasible region T. Next, we use Theorem 6.2.1 to study the stability of the two equilibrium solutions. We do not want solutions to approach $(1, 0)$ and stay there. Instead, we rather have that solutions approach (S^*, I^*), that is, we hope for $(1, 0)$ to be unstable.

We begin with $(1, 0)$. The Jacobian matrix is

$$J(S, I) = \begin{pmatrix} -\mu - \lambda I & -\lambda S \\ \lambda I & -(\mu+\gamma) + \lambda S \end{pmatrix}.$$

Thus

$$J(1, 0) = \begin{pmatrix} -\mu & -\lambda \\ 0 & -(\mu+\gamma) + \lambda \end{pmatrix}$$

with two eigenvalues

$$d_1 = -\mu \text{ and } d_2 = -(\mu+\gamma) + \lambda.$$

Clearly, $d_1 < 0$, and $d_2 > 0$ as long as $\mu + \gamma < \lambda$. Thus by Theorem 6.2.1 the equilibrium solution $(1, 0)$ is unstable. Recall that if

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

Copyright Elsevier 2022

is a nonsingular matrix, then the characteristic equation is

$$\lambda^2 - (a+d)\lambda + ad - bc = 0.$$

By introducing

$$\begin{aligned} p &= a+d, \\ q &= ad - bc, \end{aligned}$$

the characteristic equation becomes

$$\lambda^2 - p\lambda + q = 0.$$

The roots of this equation are

$$\lambda_{1,2} = \frac{1}{2}\left[p \pm \sqrt{p^2 - 4q}\right]. \tag{6.3.2}$$

Now the Jacobian at (S^*, I^*) is

$$J(S^*, I^*) = \begin{pmatrix} -\mu - \lambda I^* & -\lambda S^* \\ \lambda I^* & 0 \end{pmatrix}.$$

Using (6.3.2), we arrive at the two eigenvalues

$$d_{1,2} = \frac{-(\mu + \lambda I^*) \pm \sqrt{(\mu + \lambda I^*)^2 - 4\lambda^2 S^* I^*}}{2}$$

with negative real parts. Hence by Theorem 6.2.1 the equilibrium solution (S^*, I^*) is asymptotically stable.

6.4 Limit cycle

A central issue in the theory of nonlinear systems in differential equations is to determine the existence of closed orbits or limit cycles. Those closed orbits or limit cycles represent periodic solutions of the system. We consider the two-dimensional autonomous system

$$x' = P(x, y), \;\; y' = Q(x, y), \tag{6.4.1}$$

where P and Q are continuous on some subset of $\mathbb{R}^2$. Systems given by (6.4.1) may admit solutions that commonly tend to a limiting finite periodic solution. This limiting closed curve in the phase plane is called a *limit cycle*.

Definition 6.4.1. A limit cycle of system (6.4.1) is a closed curve, and no other solution that is a closed curve exists in its neighborhood.

Copyright Elsevier 2022

Note that every neighboring trajectory spirals and approaches the limit cycle from the inside or from the outside as $t \to \infty$ or as $t \to -\infty$.

Definition 6.4.2. If every neighboring trajectory approaches a limit cycle as $t \to \infty$ or as $t \to -\infty$, then the limit cycle is said to be *stable*.

It is hard, if not impossible, to determine if a nonlinear system admits a limit cycle. However, the next result, known as Bendixson–Dulac criteria should provide a criterion for the *nonexistence* of limit cycles or closed trajectories of the system given by (6.4.1).

Theorem 6.4.1. *(Bendixson–Dulac theorem) Suppose the first partial derivatives of $P(x, y)$ and $Q(x, y)$ are continuous on some connected subset U in $\mathbb{R}^2$. If*

$$\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y}$$

is not identically zero and has the same sign in any open set of U, then system (6.4.1) has no closed trajectory in U.

Proof. Suppose the contrary, that is, there is a closed curve C in U. Then by Green's theorem we have

$$\int_C P(x, y)dy - Q(x, y)dx = \int\int_R (\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y})dxdy, \qquad (6.4.2)$$

where R is the region enclosed by C. Let $x = x(t)$, $y = y(t)$ be a parameterization of C. Then

$$\int_C P(x, y)dy - Q(x, y)dx = \int_0^T (P\frac{dy}{dt} - Q\frac{dx}{dt})dt,$$

where T is the period of C. Using (6.4.1), we arrive at

$$\int_C P(x, y)dy - Q(x, y)dx = \int_0^T (PQ - QP)dt = 0.$$

Thus from (6.4.2) we have

$$\int\int_R (\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y})dxdy = 0,$$

which can only hold if $\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y}$ is zero or changes sign, which is a contradiction. Thus C cannot be close, and the system does not admit a limit cycle. This completes the proof. □

Example 6.11. Let g and h be differentiable functions. Consider the two-dimensional system

$$x' = g(y), \quad y' = (1 + x^2)y + h(x).$$

Copyright Elsevier 2022

Then

$$\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} = 1 + x^2 > 0, \quad x \in \mathbb{R},$$

and by Theorem 6.4.1 the system does not admit a periodic solution.

The next theorem generalizes Theorem 6.4.1. For its proof, we refer the reader to Exercise 6.20.

Theorem 6.4.2. *(Generalization of Bendixson–Dulac theorem) Suppose the first partial derivatives of* $P(x, y)$*,* $Q(x, y)$*, and* $h(x, y)$ *are continuous on some connected subset* U *in* $\mathbb{R}^2$*. If*

$$\frac{\partial (hP)}{\partial x} + \frac{\partial (hQ)}{\partial y}$$

is not identically zero and of one sign in any open set of U *in* $\mathbb{R}^2$*, then system* (6.4.1) *cannot have a closed trajectory in* U*.*

We have the following example as an application.

Example 6.12. For constants a, b, c, k, consider the two-dimensional system

$$x' = (y - a)x, \quad y' = bx + cy + ky^2.$$

Then

$$\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} = y - a + c + 2ky,$$

and hence Theorem 6.4.1 is not applicable. Let us try Theorem 6.4.2 with $h(x, y) = x^{-(2k+1)}$. Then

$$\frac{\partial (hP)}{\partial x} + \frac{\partial (hQ)}{\partial y} = (c + 2ka)x^{-(2k+1)} \neq 0$$

if $c + 2ka \neq 0$, and by Theorem 6.4.2 the system does not admit a periodic solution in the half-plane $x > 0$ or $x < 0$.

In fact, we can do better. If $x = 0$, then starting from any point on the y-axis, the equation has a solution that lies on the y-axis. Thus we conclude that the equation has no closed cycle or trajectory and hence a periodic solution in $\mathbb{R}^2$, since otherwise the uniqueness will be violated.

So far we have discussed results concerning the nonexistence of periodic solutions, or periodic trajectories, or limit cycles. Next, we look at the existence of limit cycles.

Theorem 6.4.3. *A closed orbit or limit cycle of* (6.4.1) *surrounds at least one equilibrium point of the system. In other words, if no equilibrium point of the system exists in a region, then there can be no periodic orbits in that region.*

Copyright Elsevier 2022

Let (0, 0) be the only equilibrium solution of (6.4.1). Moreover, suppose any solution of (6.4.1) that starts near the origin will spiral away from the origin. Since there are no equilibrium solutions, our first thought might be that all solutions of (6.4.1) have trajectories that spiral out to infinity. However, the next theorem, due to Poincaré and Bendixson, presents us a different scenario. It shows, under certain conditions, the existence of a limit cycle. Its proof requires high-level arguments, and we omit it.

Theorem 6.4.4. *(Poincaré–Bendixson) Suppose R is a closed bounded region of the plane enclosed by two simple curves μ_1 and μ_2. If R is free of equilibrium solutions of* (6.4.1) *and there is a trajectory C confined to R, then either C is a limit cycle, or it spirals toward a limit cycle.*

The main point of the theorem is that if we find one solution that exists for all t large enough (that is, we let t go to infinity) and stays within a bounded region, then we have found either a periodic orbit or a solution that spirals toward a limit cycle; that is, in the long term, the behavior will be very close to a periodic function. We should take the theorem more as a qualitative statement rather than something to help us in computations. In practice, it is hard to find solutions and therefore hard to show rigorously that they exist at all times. Another caveat to consider the theorem is that it only works in two dimensions. In three dimensions and higher, there is simply too much room.

As an application, we provide the following example.

Example 6.13.

$$x' = y + x[1 - x^2 - y^2], \;\; y' = -x + y[1 - x^2 - y^2]. \tag{6.4.3}$$

It is clear that (0, 0) is the only equilibrium solution of (6.4.3). Let us pass to polar coordinates. Namely,

$$x = r\cos(\theta), \;\; y = r\sin(\theta), \;\; \text{where } r^2 = x^2 + y^2,$$

and $r = r(t)$ and $\theta = \theta(t) = \tan^{-1}(\frac{y}{x})$. Thus

$$\frac{d}{dt}(x^2 + y^2) = \frac{d}{dt}r^2$$

or

$$xx' + yy' = rr'.$$

A substitution of x' and y' yields

$$r' = r(1 - r^2),$$

$$\theta' = \frac{xy' - x'y}{x^2 + y^2} = 1.$$

Copyright Elsevier 2022

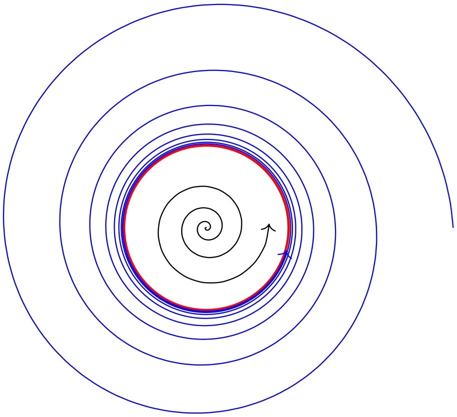

FIGURE 6.9

Limit cycle.

For constants c and k, the solutions are given by

$$r(t) = \frac{1}{\sqrt{1 + ce^{-2t}}},\ c > -1,\ \theta(t) = -t + k,\ t \geq 0.$$

For $c = 0$, we have that $r = 0$ and $(x(t), y(t)) = (\cos(t), -\sin(t))$ is a periodic solution with trajectory given by the unit circle in red (light gray in print version) in Fig. 6.9. For $c > 0$, we have $0 < r(t) < 1$, and as t increases, $r \nearrow 1$, and the corresponding solution approaches the unit circle from inside of the circle in a spiral way as $t \to \infty$, as indicated in Fig. 6.9. For $-1 < c < 0$, we have $r(t) > 1$, and as t increases, $r \searrow 1$, and the corresponding solution approaches the unit circle from outside of the circle in a spiral way as $t \to \infty$, as indicated in Fig. 6.9. Therefore the unit circle $x^2 + y^2 = 1$, given parametrically by $(x(t), y(t)) = (\cos(t), -\sin(t))$ is a *limit cycle* for (6.4.3), and it is asymptotically stable. Note that $(0, 0)$ is the only equilibrium solution inside the unit circle. As for the construction of the region R, we let $\mu_1 < \mu < \mu_2$, where $0 < \mu_1 < 1$ and $1 < \mu_2 < \infty$, and define the annulus region

$$R = \{(x, y) : \mu_1 < x^2 + y^2 = 1 < \mu_2\}.$$

Clearly, R contains no equilibrium solution, and by Theorem 6.4.4, there is a periodic cycle in R.

6.5 Lotka–Volterra competition model

If two populations $x_1(t)$ and $x_2(t)$ were growing logistically and not affecting each other, their growth can be described by two uncoupled logistic equations

Copyright Elsevier 2022

$$\begin{cases} x_1'(t) = r_1 x_1(t)\left(1 - \frac{x_1(t)}{K_1}\right), \\ x_2'(t) = r_2 x_2(t)\left(1 - \frac{x_2(t)}{K_2}\right), \\ x_1(0) > 0,\ x_2(0) > 0, \end{cases}$$

where $r_i, i = 1, 2$, are the growth rates (birth–death), and $K_i, i = 1, 2$, are positive constants. If the two populations were competing for the same resources, then the growth rate of each population is affected by the other. In that case the model becomes

$$\begin{cases} x_1'(t) = r_1 x_1(t)\left(1 - \frac{x_1(t)}{K_1} - \lambda_1 x_2(t)\right), \\ x_2'(t) = r_2 x_2(t)\left(1 - \frac{x_2(t)}{K_2} - \lambda_2 x_1(t)\right), \\ x_1(0) > 0,\ x_2(0) > 0, \end{cases}$$

where $\lambda_i, i = 1, 2$, are positive constants. To simplify the calculations, we convert the system by using non-dimensional variables by measuring x_1 in units of K_1, x_2 in units of K_2, and time in units of $\frac{1}{r_1}$. We let

$$x_1(t) = K_1 x(t),\ x_2(t) = K_2 y(t),\ \text{ and } t = \frac{s}{r_1}.$$

By the chain rules, it follows that

$$K_1 \frac{dx}{ds} = \frac{dx_1}{dt}\frac{dt}{ds} = \frac{dx_1}{dt}\frac{1}{r_1}$$

or

$$x_1'(t) = r_1 K_1 \frac{dx}{ds}.$$

Substituting this back into the first equation of the model, we arrive at

$$r_1 K_1 \frac{dx}{ds} = r_1 K_1 x(s)\left(1 - x(s) - \lambda_1 K_2 y(s)\right),$$

from which we get

$$\frac{dx}{ds} = x(s)\left(1 - x(s) - \lambda_1 K_2 y(s)\right).$$

Similarly, we obtain

$$\frac{dy}{ds} = r y(s)\left(1 - y(s) - \lambda_2 K_1 x(s)\right),$$

where $r = \frac{r_2}{r_1}$.

Copyright Elsevier 2022

Interchanging s with t and letting $\mu_1 = \lambda_1 K_2$ and $\mu_2 = \lambda_2 K_1$, we arrive at the dimensionless Lotka–Volterra competition model

$$\begin{cases} x'(t) = x(t)\big(1 - x(t) - \mu_1 y(t)\big), \\ y'(t) = ry(t)\big(1 - y(t) - \mu_2 x(t)\big), \\ x(0) = x_0 > 0,\ y(0) = y_0 > 0. \end{cases} \tag{6.5.1}$$

Next, we show that solutions of (6.5.1) are positive and remain bounded for all $t > 0$.

Proposition 6.1. *If $x(t)$, $y(t)$ is a solution pair of (6.5.1) with positive initial conditions x_0 and y_0, respectively, then they are positive and bounded for all $t > 0$.*

Proof. Let $x(t)$, $y(t)$ be a solution of (6.5.1) with positive initial conditions x_0 and y_0. Dividing the first equation of (6.5.1) by $x(t)$ and the second equation by $y(t)$, respectively, and integrating, we get the integral relations

$$x(t) = x_0 e^{\int_0^t \left(1 - x(s) - \mu_1 y(s)\right) ds}$$

and

$$y(t) = y_0 e^{r \int_0^t \left(1 - y(s) - \mu_2 s(s)\right) ds}.$$

We see that if the initial conditions are positive, then the components of the solution are positive. It is left to show that the solutions remain bounded for all $t > 0$. Since x and y are positive, we have that

$$x(t)\big(1 - x(t) - \mu_1 y(t)\big) \le x(t)\big(1 - x(t)\big)$$

and

$$ry(t)\big(1 - y(t) - \mu_2 x(t)\big) \le ry(t)\big(1 - y(t)\big).$$

It follows that

$$x'(t) \le x(t)\big(1 - x(t)\big) \text{ and } y'(t) \le ry(t)\big(1 - y(t)\big).$$

From now on, we write x for $x(t)$ and y for $y(t)$. Consider the differential equation

$$z' = z(1 - z),\ z(0) = x(0) = x_0.$$

Separating the variables and then integrating, we get $\int \frac{dz}{z(1-z)} = \int dt$. Using partial fractions on the left side integral, we obtain $\mathrm{Ln}|\frac{z}{1-z}| = t + C$. Taking the exponential on both sides, solving for z, and then applying the initial condition, we arrive at the unique solution

$$z(t) = \frac{x_0 e^t}{1 + x_0(e^t - 1)} \to 1 \text{ as } t \to \infty.$$

Copyright Elsevier 2022

Since z is positive and has a limit, we conclude that z is bounded for all $t > 0$. Moreover,

$$z(t) \leq 1 \text{ as } t \to \infty.$$

From this discussion we arrive at

$$x(t) \leq z(t) \leq 1.$$

Similar results can be obtained for $y(t)$. This concludes the proof. □

Setting the right sides of (6.5.1) equal to zero, we obtain the equilibrium solutions

$$E_0 = (0, 0), \ E_1 = (0, 1), \ E_2 = (1, 0),$$

and

$$E_3, \text{ which comprises of the solutions (if they exist) of } x + \mu_1 y = 1, \ \mu_2 x + y = 1.$$

Next, we use Theorem 6.2.1 to analyze the stability of the equilibrium solutions. The Jacobian matrix is

$$J(x, y) = \begin{pmatrix} 1 - 2x - \mu_1 y & -\mu_1 x \\ -r\mu_2 y & r(1 - 2x - \mu_2 x) \end{pmatrix}.$$

For $E_0 = (0, 0)$, we have

$$J(0, 0) = \begin{pmatrix} 1 & 0 \\ 0 & r \end{pmatrix}$$

with eigenvalues $\lambda = 1, r$, and hence by Theorem 6.2.1 and Remark 6.3 E_0 is unstable or repeller. At E_1,

$$J(0, 1) = \begin{pmatrix} 1 - \mu_1 & 0 \\ -r\mu_2 & -r \end{pmatrix}$$

with eigenvalues $\lambda = 1 - \mu_1$ and $-r$, and hence by Theorem 6.2.1 and Remark 6.3 E_1 is either a saddle or asymptotically stable. Similarly, at E_2,

$$J(1, 0) = \begin{pmatrix} -1 & -\mu_1 \\ 0 & r(1 - \mu_2) \end{pmatrix}$$

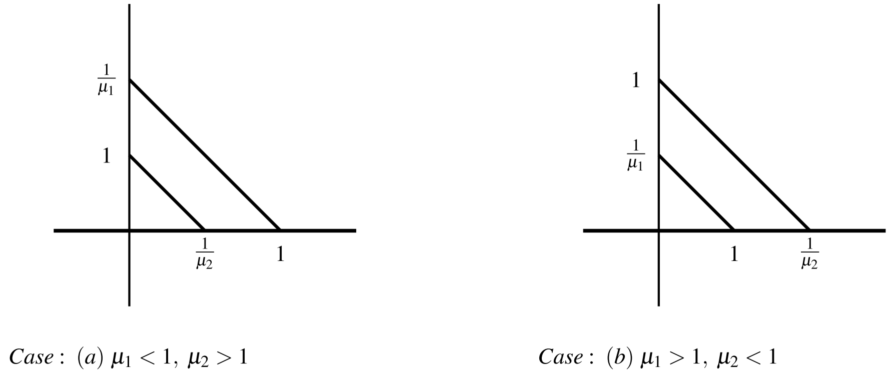
with eigenvalues $\lambda = -1$ and $r(1 - \mu_2)$, and hence by Theorem 6.2.1 and Remark 6.3 E_2 is either a saddle or asymptotically stable. For, E_3 we solve the system

$$x + \mu_1 y = 1, \ \mu_2 x + y = 1.$$

After some calculations, we obtain

$$E_3 = (\frac{1 - \mu_1}{1 - \mu_1\mu_2}, \frac{1 - \mu_2}{1 - \mu_1\mu_2}).$$

Copyright Elsevier 2022



Case: (*a*) $\mu_1 < 1,\ \mu_2 > 1$ *Case*: (*b*) $\mu_1 > 1,\ \mu_2 < 1$

FIGURE 6.10

No equilibrium points in the first quadrant.

The stability of the equilibrium solution of E_3 is important to biologists since it shows the coexistence of both species. We will analyze the stability by considering different cases that are based on the eigenvalues.

Case (a): $\mu_1 < 1, \mu_2 > 1$**.**
In this case the lines $x + \mu_1 y = 1$ and $\mu_2 x + y = 1$ do not intersect in the first quadrant, and it follows that E_3 is not an equilibrium solution as depicted in Fig. 6.10. In addition, in Case (a), E_2 is asymptotically stable, and E_1 is a saddle point. Since the interior of the first quadrant does not contain any equilibrium solution, it follows from Theorem 6.4.3 that there is no periodic solution in the first quadrant. Recall that by Theorem 6.4.3 a closed orbit or limit cycle surrounds at least one equilibrium point. Thus by Theorem 6.4.3 the omega limit set of any trajectory is the equilibrium solution E_2, and hence E_2 is globally asymptotically stable; see Fig. 6.11. The biological meaning is that population x wins the competition. In other words, population y becomes instinct.

Case (b): $\mu_1 > 1, \mu_2 < 1$**.**
In this case the roles of E_1 and E_2 are reversed, but still only one competitor survives.

Next, we consider the cases where E_3 is in the first quadrant, that is, E_3 is an equilibrium solution.

It turned out that E_3 is an equilibrium solution in two cases.

Case (c): $\mu_1 < 1, \mu_2 < 1$ and **Case (d):** $\mu_1 > 1, \mu_2 > 1$**.**
Next, we make use of Theorem 6.4.2 (generalization of the Bendixson–Dulac theorem) to study the possibilities of the existence of a periodic solution that surrounds E_3. Let $h(x, y) = \frac{1}{xy}$. Then h is a continuously differentiable function in $G = \{(x, y) : x > 0, y > 0\}$ with

$$\frac{\partial}{\partial x}\Big[\frac{1}{xy}x\big(1 - x - \mu_1 y\big)\Big] = -\frac{1}{y}$$

Copyright Elsevier 2022

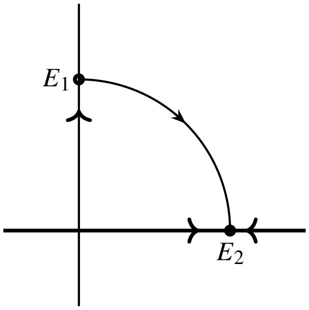


FIGURE 6.11

E_2 is globally asymptotically stable.

and

$$\frac{\partial}{\partial y}\Big[\frac{1}{xy}ry\big(1-y-\mu_2x\big)\Big]=-\frac{r}{x}.$$

Thus

$$\frac{\partial}{\partial x}\Big[\frac{1}{xy}x\big(1-x-\mu_1y\big)\Big]+\frac{\partial}{\partial y}\Big[\frac{1}{xy}ry\big(1-y-\mu_2x\big)\Big]=-(\frac{1}{y}+\frac{r}{x}),$$

which is negative in G. Therefore there is no periodic solution in the first quadrant in both case (c) and case (d).

Let (x^*,y^*) be a solution of $x+\mu_1y=1$, $\mu_2x+y=1$, that is, $(x^*,y^*)=(\frac{1-\mu_1}{1-\mu_1\mu_2},\frac{1-\mu_2}{1-\mu_1\mu_2})$. Then

$$\begin{aligned}J(x^*,y^*)&=\begin{pmatrix}1-2x^*-\mu_1y^* & -\mu_1x^*\\ -r\mu_2y^* & r(1-2y^*-\mu_2x^*)\end{pmatrix}\\&=\begin{pmatrix}1-2x^*-\mu_1\frac{1-\mu_2}{1-\mu_1\mu_2} & -\mu_1x^*\\ -r\mu_2y^* & r(1-2y^*-\mu_2\frac{1-\mu_1}{1-\mu_1\mu_2})\end{pmatrix}\\&=\begin{pmatrix}-x^* & -\mu_1x^*\\ -r\mu_2y^* & -ry^*\end{pmatrix},\end{aligned}$$

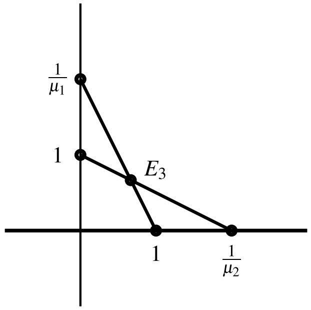
and $\operatorname{tra}(J(x^*,y^*))=-x^*-ry^*<0$ for $x^*,y^*>0$ implies that the sum of the eigenvalues is negative. Moreover,

$$\det(J(x^*,y^*))=rx^*y^*-r\mu_1\mu_2x^*y^*=rx^*y^*(1-\mu_1\mu_2).$$

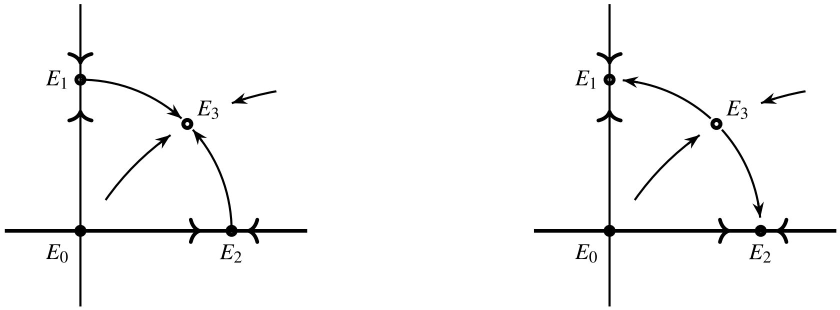
As

$$\det(J(x^*,y^*)-\lambda I)=\lambda^2-\operatorname{tra}(J(x^*,y^*))\lambda+\det(J(x^*,y^*)),$$

Copyright Elsevier 2022



Case(c): $\mu_1 < 1,\ \mu_2 < 1$ *Case*(d): $\mu_1 > 1,\ \mu_2 > 1$



(e): $\mu_1 < 1,\ \mu_2 < 1,\ 1-\mu_1\mu_2 > 0$ (f): $\mu_1 > 1,\ \mu_2 > 1, 1-\mu_1\mu_2 < 0$

FIGURE 6.12

Coexistence.

we have that

$$\lambda^2 + (x^* + ry^*)\lambda + rx^*y^*(1 - \mu_1\mu_2) = 0.$$

It follows that the eigenvalues are given by

$$\lambda = \frac{-x^* - ry^* \pm \sqrt{(x^* + ry^*)^2 - 4rx^*y^*(1 - \mu_1\mu_2)}}{2}.$$

So E_3 is asymptotically stable if $1 - \mu_1\mu_2 > 0$ and a saddle if $1 - \mu_1\mu_2 < 0$. Fig. 6.12(d) and (f).

If $\mu_1\mu_2 = 1$, then the two lines are parallel or coincident. If coincident, then there is a line of equilibrium solutions, and if parallel, then cases (a) and (b) apply. In case (c), $1 - \mu_1 > 0$ and $1 - \mu_2 > 0$, so E_1 and E_2 are saddle unstable points. Since $\mu_1\mu_2 < 1$, E_3 is an attractor, that is, all solutions tend to E_3. In that case the two populations coexist. See Fig. 6.12(d).

Copyright Elsevier 2022

In case (d), $\mu_1 - 1 > 0$ and $\mu_2 - 1 > 0$, and hence E_1 and E_2 are asymptotically stable. Also, in case (d) $\mu_1\mu_2 > 1$, and so E_3 is a saddle point. See Fig. 6.12(f). Here the initial conditions determine the winner.

6.6 Bifurcation in planar systems

We consider the two-dimensional autonomous system

$$x' = P(x, y, \mu),\;\; y' = Q(x, y, \mu) \tag{6.6.1}$$

depending upon a real parameter μ. We assume that P and Q are continuous in all arguments on some subset of $\mathbb{R}^2$. As μ changes values or signs, the behavior of solutions changes and may result in bifurcation points. For example, as we move across a particular equilibrium solution, the stability may change from stable to unstable, and vice versa. We begin by considering the following example.

Example 6.14. Consider the two-dimensional linear system

$$x' = x + \mu y,\;\; y' = x - y$$

for parameter μ. The matrix

$$\begin{pmatrix} 1 & \mu \\ 1 & -1 \end{pmatrix}$$

has the eigenvalues

$$\lambda = \pm\sqrt{1+\mu}.$$

If $\mu > -1$, then the eigenvalues are real with opposite signs, and therefore the origin $(0, 0)$ is a saddle point (unstable). For the particular value $\mu = -1$, the system becomes

$$x' = x - y,\;\; y' = x - y$$

and results in the whole line $y = x$ of fixed points. If $\mu < -1$, then the eigenvalues are purely imaginary, and the origin $(0, 0)$ is a center (stable). As $\mu > -1$ decreases to $\mu < -1$, the nature of the solution changes at $\mu = -1$; as a result, the equilibrium solution $(0, 0)$ changes from an unstable saddle to a stable center as μ passes the critical value -1. Thus we have a *bifurcation* at $\mu = -1$.

Example 6.15. Consider the planar autonomous system

$$x' = -y - x(x^2 + y^2 - \mu),\;\; y' = x - y(x^2 + y^2 - \mu).$$

It is clear that $(0, 0)$ is the only equilibrium point. We rewrite the system in the form

$$\begin{pmatrix} x \\ y \end{pmatrix}' = \begin{pmatrix} \mu & -1 \\ 1 & \mu \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} -x(x^2+y^2) \\ -y(x^2+y^2) \end{pmatrix}.$$

Copyright Elsevier 2022

The eigenvalues of

$$A = \begin{pmatrix} \mu & -1 \\ 1 & \mu \end{pmatrix}$$

are $\mu \pm i$.

(1) If $\mu < 0$, then the trajectories spiral toward the origin, and the origin is asymptotically stable by Theorem 6.2.1.
(2) If $\mu > 0$, then the origin is unstable for the nonlinear system.
(3) If $\mu = 0$, then Theorem 6.2.1 says nothing about the stability or instability about the origin of the nonlinear system.

Next we examine in more detail the trajectories of the system by using polar coordinates as we did in Example 6.8. By doing so we arrive at

$$r' = r(\mu - r^2) \quad \text{and} \quad \theta' = 1. \tag{6.6.2}$$

Separating the variables and using partial fractions we arrive at

$$\int \frac{dr}{r(r - \sqrt{\mu})(r + \sqrt{\mu})} = t + k \quad \text{for some constant } k.$$

This leads to the solution

$$r(t) = \frac{\sqrt{\mu}}{\sqrt{1 + ce^{-2\mu t}}}. \tag{6.6.3}$$

Similarly, if we choose $\theta(0) = 0$, then we have $\theta(t) = t$.

Assume that $\mu > 0$ and consider the following three cases.

(3a) When $c = 0$, we have from (6.6.3) $r(t) = \sqrt{\mu}$, which represents a periodic solution with radius $\sqrt{\mu}$.
(3b) If $c < 0$, then (6.6.3) represents an orbit or trajectory that spirals counterclockwise toward the circle $r(t) = \sqrt{\mu}$ from the outside.
(3c) If $c > 0$, then (6.6.3) represents an orbit or trajectory that spirals counterclockwise toward the circle $r(t) = \sqrt{\mu}$ from the inside.

Let $0 < \mu_1 < \mu < \mu_2$ and define the annulus region

$$R = \{(x, y) : \mu_1 < x^2 + y^2 < \mu_2\}.$$

Clearly, R contains no equilibrium solution, and then cases (3a)–(3c) prove that the circle given by $r^2(t) = \mu$ or $x^2 + y^2 = \mu$ is a *stable limit cycle* and the origin is unstable.

Next, we examine the stability of the origin when $\mu = 0$.

In this case (6.6.2) gives

$$r' = -r^3,$$

Copyright Elsevier 2022

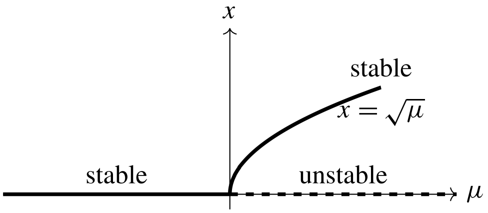


FIGURE 6.13

Bifurcation diagram for Example 6.15.

which has the solution

$$r(t) = \frac{1}{\sqrt{2t+K}}$$

for a suitable constant K. Clearly, $r(t) \to 0$ as $t \to \infty$, and hence the zero solution (or the origin) is asymptotically stable (spirally stable).

Finally, for $\mu < 0$, from (6.6.2) we have

$$r' = r(r^2 + l^2) \text{ and } \theta' = 1,$$

where $l^2 = -\mu > 0$. Separating the variables and using partial fractions, we arrive at

$$\int \frac{dr}{r(r^2+l^2)} = -dt \text{ for some constant } k.$$

This leads to the solution

$$r(t) = \frac{cl^2 e^{-2l^2 t}}{1 - cl^2 e^{-2l^2 t}} \text{ for some constant } c.$$

Clearly, $r(t) \to 0$, as $t \to \infty$, and hence the zero solution (or the origin) is asymptotically stable (spirally stable). In conclusion, for $\mu \leq 0$, the origin $(0, 0)$ is stable, and for $\mu > 0$, (0,0) is unstable, and $r = \sqrt{\mu}$ is stable. Thus as μ passes through the critical value $\mu = 0$ from negative to positive, the origin changes from stable spiral to unstable spiral, and there appears a new limit cycle that is a periodic solution. This type of bifurcation is common and known as *Hopf bifurcation*.

The bifurcation diagram is shown in Fig. 6.13.

The next theorem provides a necessary condition for the existence of Hopf bifurcation. The proof is complicated, and hence we omit it.

Theorem 6.6.1. *Consider the two-dimensional autonomous system*

$$x' = P(x, y, \mu), \ y' = Q(x, y, \mu) \tag{6.6.4}$$

Copyright Elsevier 2022

depending upon a real parameter μ, where P and Q are differentiable in the neighborhood of $(0, 0, 0)$. Assume that for small μ,

$$P(0, 0, \mu) = Q(0, 0, \mu) = 0. \tag{6.6.5}$$

Let the Jacobian

$$J(0, 0, 0) = \begin{pmatrix} P_x(0, 0, 0) & P_y(0, 0, 0) \\ Q_x(0, 0, 0) & Q_y(0, 0, 0) \end{pmatrix} = \begin{pmatrix} 0 & -w \\ w & 0 \end{pmatrix} \text{ for some } w \neq 0. \tag{6.6.6}$$

Let

$$\begin{aligned} a = {} & \frac{1}{16}\big(P_{xxx} + Q_{xxy} + P_{xyy} + Q_{yyy}\big) \\ & + \frac{1}{16w}\big(P_{xy}(P_{xx} + P_{yy}) - Q_{xy}(Q_{xx} + Q_{yy}) - P_{xx}Q_{xx} + P_{yy}Q_{yy}\big) \end{aligned} \tag{6.6.7}$$

evaluated at $(0, 0, 0)$ with $a \neq 0$. Suppose that

$$a\big(P_{\mu x} + Q_{\mu y}\big) > 0. \tag{6.6.8}$$

Then for sufficiently small $\mu < 0$, there is a unique periodic solution with amplitude $A(\mu)$ such that

$$\lim_{\mu \to 0^-} \frac{A(\mu)}{\sqrt{|\mu|}} = c > 0.$$

If

$$a\big(P_{\mu x} + Q_{\mu y}\big) < 0, \tag{6.6.9}$$

then the periodic solution exists for $\mu > 0$. The stability of the periodic solution is determined by the sign of

$$P_{\mu x} + Q_{\mu y} \tag{6.6.10}$$

and is the opposite of the stability of the zero solution in the range of μ where the periodic solution exists.

Example 6.16. As an application of Theorem 6.6.1, we consider the system given in Example 6.14. It readily follows that the Jacobian

$$J(0, 0, 0) = \begin{pmatrix} \mu & -1 \\ 1 & \mu \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Thus condition (6.6.6) is satisfied with $w = 1$. After simple calculations, it follows that (6.6.7) evaluated at $(0, 0, 0)$ implies that $a = -1$. Moreover,

$$a\big(P_{\mu x} + Q_{\mu y}\big) = -1(1 + 1) < 0.$$

Thus by Theorem 6.6.1, the system possesses a periodic solution for $\mu > 0$ that is stable (spirally stable) since the origin is unstable in the region where μ is positive.

Copyright Elsevier 2022

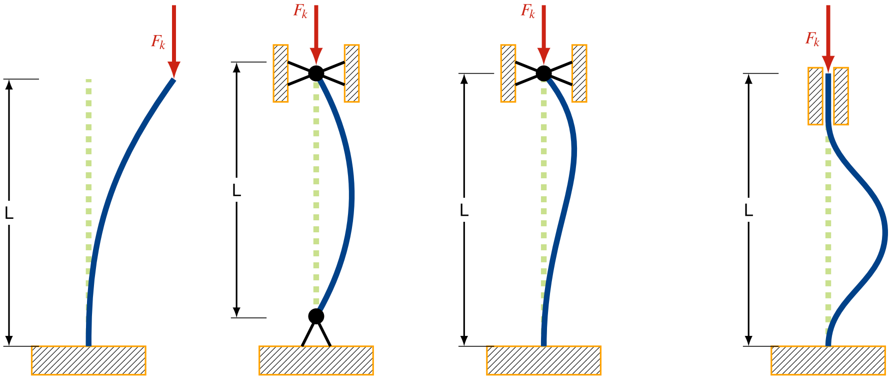

FIGURE 6.14

Buckling beam.

We end this section with an application to Euler's buckling beam.

Example 6.17. (Euler's buckling beam) One of the most famous applications to bifurcations is the so-called Euler's buckling beam. Consider different scenarios of beams in Fig. 6.14, where excessive pressure is applied to the beam. The beam can support a small force or pressure, but as the force is increased, the beam will go through a qualitative change in its vertical standing position. At one point, as we keep increasing the force, the beam position will get compromised and results in a so-called *buckling,* that is, there will be a critical value at which if the pressure is increased beyond it, then the beam will buckle. Fig. 6.14 provides different situations for such buckling beams along with supported ends. As for modeling, suppose we have a beam of length one unit and the beam is placed along the horizontal axis with one end supported by a fixed wall and a force $\mathbb{F} \geq 0$ applied along its axis. Let $\delta > 0$ be the viscous damping, and let $K > 0$ be the stiffness. The small deflection of the beam is denoted by $v(x, t)$, where x denotes the horizontal axes. After transforming the model from a partial differential equation to a second-order differential equation, it was shown in [27] that the amplitude u in variable time t satisfies the second-order differential equation

$$u''(t) + \delta u'(t) - \pi^2(\mathbb{F} - \pi^2)u(t) + \frac{1}{2}K\pi^4 u^3(t) = 0. \tag{6.6.11}$$

To better study the differential equation, we put it in the system form

$$\begin{cases} x' = y, \\ y' = \pi^2(\mathbb{F} - \pi^2)x - \delta y - \frac{1}{2}K\pi^4 x^3, \end{cases} \tag{6.6.12}$$

where the force $\mathbb{F}$ is the only parameter. The system has three equilibrium solutions

Copyright Elsevier 2022

$$(0,0),\ \left(\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0\right),\ \text{and}\ \left(-\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0\right).$$

Note that the equilibrium solutions

$$\left(\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0\right)\ \text{and}\ \left(-\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0\right)$$

are only valid for $\mathbb{F} > \pi^2$.

Now

$$J(0,0) = \begin{pmatrix} 0 & 1 \\ \pi^2(\mathbb{F}-\pi^2) & -\delta \end{pmatrix}$$

with eigenvalues

$$\lambda = \frac{-\delta \pm \sqrt{\delta^2 + 4\pi^2(\mathbb{F}-\pi^2)}}{2},$$

and, as a consequence, $(0,0)$ is stable if $\mathbb{F} < \pi^2$ and unstable if $\mathbb{F} > \pi^2$. The physical implication is that the beam will buckle if $\mathbb{F} > \pi^2$.

Now we consider the equilibrium solution $(\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0)$ for $\mathbb{F} > \pi^2$. We translate it to the origin with transformation

$$x_1 = x - \sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},\ y_1 = 0$$

and arrive at the linearized matrix

$$J(0,0) = \begin{pmatrix} 0 & 1 \\ -2\pi^2(\mathbb{F}-\pi^2) & -\delta \end{pmatrix}$$

with eigenvalues

$$\lambda = \frac{-\delta \pm \sqrt{\delta^2 - 8\pi^2(\mathbb{F}-\pi^2)}}{2}.$$

It follows that $(0,0)$ is stable if $\mathbb{F} > \pi^2$ and that the equilibrium solution $(\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0)$ is stable for $\mathbb{F} > \pi^2$. The physical implication is that the beam will buckle if $\mathbb{F} > \pi^2$.

Similarly, we can easily show that the equilibrium solution $(-\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}},0)$ is also stable for $\mathbb{F} > \pi^2$. Thus we have a pitchfork bifurcation at $\mathbb{F} = \pi^2$. The bifurcation diagram in Fig. 6.15 shows that bending is symmetric and can take place in the negative direction as well.

Bifurcation diagram for $u = \pm\sqrt{\frac{2(\mathbb{F}-\pi^2)}{K\pi^2}}$.

6.7 Manifolds and Hartman–Grobman theorem

In the study of dynamical systems and differential equations, the stable manifold theorem is an important result about the structure of the set of orbits approaching a given hyperbolic fixed point. Stable manifolds are directly related to the important Hartman–Grobman theorem, which states that the flow generated by a smooth vector field in a neighborhood of a hyperbolic equilibrium point is topologically conjugate with the flow generated by its linearization. Hartman's counterexample shows that, in general, the conjugacy cannot be taken to be C^1. However, the stable manifold theorem tells us that there are important structures for the two flows that can be matched up by smooth changes of variables.

Let $f : E \subseteq \mathbb{R}^n \to \mathbb{R}^n$ be C^1 and consider the autonomous nonlinear differential equation

$$x' = f(x). \tag{6.7.1}$$

Definition 6.7.1. An equilibrium point x_0 of (6.7.1) is called *hyperbolic* if none of the eigenvalues of the matrix $Df(x_0)$ has a zero real part, where throughout this section, we adopt the notation

$$Df(x_0) = J(x_0).$$

For example, the system

$$x' = y, \quad y' = -x - x^3 - 3y$$

has $(0, 0)$ as its only equilibrium solution. The linearization at $(0, 0)$ is

$$Df(0,0) = \begin{pmatrix} 0 & 1 \\ -1 & -3 \end{pmatrix},$$

Copyright Elsevier 2022

which has the eigenvalues

$$\lambda = \frac{-2 \pm \sqrt{5}}{2}.$$

Thus (0, 0) is a hyperbolic equilibrium solution since none of the eigenvalues has the zero real part.

Our aim is to show that the local behavior of the nonlinear system (6.7.1) near a hyperbolic equilibrium point x_0 is qualitatively determined by the behavior of the linear system

$$x' = Ax, \tag{6.7.2}$$

where the matrix $A = Df(x_0)$. Now we define the flow or trajectory of (6.7.1) that suits our notations for this section. Denote the maximal interval of existence (α, β) of the solution $\phi(t, x_0)$ of the IVP

$$x' = f(x), \;\; x(0) = x^* \tag{6.7.3}$$

by $I(x^*)$ since α or β usually depend on x^*. If $x^* \in E$ and $t \in I(x^*)$, then the set of mappings ϕ_t defined by

$$\phi_t(x^*) = \phi(t, x^*)$$

is called the flow of (6.7.1). We define the set $\Omega \subseteq \mathbb{R} \times E$ as

$$\Omega = \{(t, x^*) \in \mathbb{R} \times E : \; t \in I(x^*)\}.$$

We leave it an exercise to show that the set Ω is an open subset of $\mathbb{R} \times E$ and $\phi \in C^1(\Omega)$.

Theorem 6.7.1. *Let* $E \subseteq \mathbb{R}^n$ *be open with* $f \in C^1(E)$*, and let* $\phi_t : E \to E$ *be the flow of* (6.7.1) *defined for all* $t \in \mathbb{R}$.
(i) The set $S \subseteq E$ *is said to be invariant with respect to the flow* ϕ_t *if* $\phi_t(S) \subseteq S$ *for all* $t \in \mathbb{R}$.
(ii) The set E *is said to be positively (or negatively) invariant with respect to the flow* ϕ_t *if* $\phi_t(S) \subseteq S$ *for all* $t > 0$ *(or* $t < 0$).

We furnish the following example.

Example 6.18. Consider the nonlinear system of differential equations

$$x' = \begin{pmatrix} x_1 + x_2^2 \\ -x_2 \end{pmatrix}$$

with

$$x(0) = \begin{pmatrix} a \\ b \end{pmatrix} = x^*.$$

Copyright Elsevier 2022

Now $x_2' = -x_2$ has the solution $x_2 = be^{-t}$. Substituting this solution of x_2 into the first differential equation and using the variation of parameters formula, we arrive at $x_1 = ae^t + \frac{1}{3}b^2(e^t - e^{-2t})$. Thus

$$\phi_t(x^*) = \begin{pmatrix} ae^t + \frac{1}{3}b^2(e^t - e^{-2t}) \\ be^{-t} \end{pmatrix}.$$

Next, we show that the set

$$S = \{x \in \mathbb{R}^2 : x_1 = -x_2^2/3\}$$

is invariant under the flow ϕ_t. Let $x^* \in S$. Then $a = -b^2/3$, and it follows that

$$\phi_t(x^*) = \begin{pmatrix} -\frac{1}{3}b^2e^{-2t} \\ be^{-t} \end{pmatrix} \in S.$$

Therefore $\phi_t(S) \subseteq S$ for all $t \in \mathbb{R}$. We will see later that the set S will be called the *stable manifold* for system (6.7.1).

We are ready to formally define stable and unstable manifolds.

Consider the linear system given by (6.7.2) and suppose the eigenvalues of A and their corresponding generalized eigenvectors are $\lambda_j = \alpha_j + i\beta_j$ and $k_j + i\, d_j$ for $j = 1, 2, \ldots, n$. Let those vectors be the columns of the matrix P. Then $P^{-1}AP = J$, where J is the Jordan form of A. Then the sets

$$E^s := Span\{k_j, d_j : \alpha_j < 0\},$$

$$E^u := Span\{k_j, d_j : \alpha_j > 0\},$$

$$E^c := Span\{k_j, d_j : \alpha_j = 0\}$$

are the *stable, unstable*, and *center* subspaces for system (6.7.2).

Definition 6.7.2. Suppose that x_0 is a hyperbolic equilibrium point of (6.7.1).
(i) The *stable manifold* of x_0 is the set

$$W^s(x_0) = \{x^* \in E : \lim_{t\uparrow\infty} \phi_t(x^*) = x_0\}.$$

(ii) The *unstable manifold* of x_0 is the set

$$W^u(x_0) = \{x^* \in E : \lim_{t\downarrow-\infty} \phi_t(x^*) = x_0\}.$$

We have the following example.

Copyright Elsevier 2022

Example 6.19. Consider the system given in Example 6.18. Then the eigenvalues of $A = Df(0,0)$ are $\lambda = \pm 1$. If $\lambda = 1$, then its corresponding eigenvector is given by $v_1 = (1,0)^T$. Similarly, $v_2 = (0,1)^T$ is the corresponding eigenvector for $\lambda = -1$. Thus

$$E^u = \{(x,y) \in \mathbb{R}^2 : y = 0\}$$

and

$$E^s = \{(x,y) \in \mathbb{R}^2 : x = 0\}.$$

Now $\lim_{t\uparrow\infty} \phi_t(x^*) = x_0$ if and only if $a + b^2/3 = 0$. Thus the stable manifold is

$$W^s(x_0) = \{x^* \in \mathbb{R}^2 : a = -b^2/3\}.$$

Similarly, $\lim_{t\downarrow-\infty} \phi_t(x^*) = (0,0)$ if and only if $b = 0$. Thus the unstable manifold is

$$W^u(0,0) = \{x^* \in \mathbb{R}^2 : b = 0\}.$$

6.7.1 The stable manifold theorem

The stable manifold theorem that we are about to state and give a sketch of its proof states that (6.7.1) has stable and unstable manifolds W^s and W^u that are tangent at x_0 to the stable and unstable subspaces E^s and E^u of the linearized system (6.7.2), where x_0 is a hyperbolic equilibrium solution of (6.7.1). Furthermore, W^s and W^u are of the same dimensions as E^s and E^u. Besides, W^s and W^u are positively and negatively invariant under ϕ_t, respectively, and satisfy

$$\lim_{t\uparrow\infty} \phi_t(x^*) = x_0 \quad \text{for all } \; x^* \in W^s,$$

$$\lim_{t\downarrow-\infty} \phi_t(x^*) = x_0 \quad \text{for all } \; x^* \in W^u.$$

We furnish the following example that should serve as warm up.

Example 6.20. Let $g \in C^1(E)$, where $E \subseteq \mathbb{R}^2$ is an open set containing $(0,0)$. Consider the nonlinear system

$$\begin{cases} x' = -x, \\ y' = y + g(x), \end{cases}$$

where we assume that $g(0) := g(0,0) = 0$ and that the function g may contain linear terms. The only equilibrium solution of the system is the origin and the Jacobian is

$$Df(0,0) = \begin{pmatrix} -1 & 0 \\ g'(0) & 1 \end{pmatrix}.$$

Copyright Elsevier 2022

Then the eigenvalues of $A = Df(0,0)$ are $\lambda = \pm 1$, and the zero equilibrium is hyperbolic. If $\lambda = 1$, then its corresponding eigenvector is given by $v_1 = (0,1)^T$. Similarly, $v_2 = (2, -g'(0))^T$ is the corresponding eigenvector for $\lambda = -1$. Thus

$$E^u = \{(x,y) \in \mathbb{R}^2 : x = 0\}$$

and

$$E^s = \{(x,y) \in \mathbb{R}^2 : y = -\frac{1}{2}g'(0)x\}.$$

To find the stable and unstable manifolds, we directly solve the system. Assume an initial point $x(0) = a$, $y(0) = b$ for $a, b \in \mathbb{R}$. The first equation in the system has the solution

$$x(t) = ae^{-t}.$$

Substituting x back into the second equation and using the variation of parameters formula, we arrive at

$$y(t) = be^t + e^t \int_0^t e^{-s} g(ae^{-s}) ds.$$

Making the substitution $u = e^{-s}$, we arrive at the flow

$$\phi_t(c) = \begin{pmatrix} ae^{-t} \\ be^t + e^t \int_{e^{-t}}^1 g(au)du \end{pmatrix}.$$

If $c = (a,b)^T \in \mathbb{R}^2$ is in the unstable manifold $W^u(0,0)$, then $\lim_{t\downarrow -\infty} \phi_t(c) \to 0$. Then from the first component of ϕ_t it follows that $\lim_{t\downarrow -\infty} ae^{-t} = 0$ if and only if $a = 0$. Substituting $a = 0$ into the second component of ϕ_t and taking the limit, that is, $\lim_{t\uparrow\infty} \left(be^1 + e^t \int_{e^{-t}}^t g(0)ds\right) = \lim_{t\downarrow -\infty} be^t = 0$ (since $g(0) = 0$), it follows that

$$W^u(0,0) = \{(x,y) \in \mathbb{R}^2 : x = 0\}.$$

Similarly, if $c = (a,b)^T \in \mathbb{R}^2$ is in the stable manifold $W^s(0,0)$, then $\lim_{t\uparrow\infty} \phi_t(c) \to 0$. Then from the first component of ϕ_t it follows that $\lim_{t\uparrow\infty} ae^{-t} = 0$ for any a. From the second component of ϕ_t we have

$$\lim_{t\uparrow\infty} e^t \left(b + e^t \int_{e^{-t}}^t g(0)ds\right) = 0. \tag{6.7.4}$$

To that effect, we claim that

$$b = -\int_0^1 g(au)du.$$

Copyright Elsevier 2022

To see that this satisfies (6.7.4), we first notice that

$$\int_0^1 g(au)du = \int_0^{e^{-t}} g(au)du + \int_{e^{-t}}^1 g(au)du.$$

Then it follows

$$\lim_{t\uparrow\infty} e^t \Big(\int_{e^{-t}}^1 g(au)du - \int_0^1 g(au)du \Big) = - \lim_{t\uparrow\infty} e^t \int_0^{e^{-t}} g(au)du.$$

We must show that the term $e^t \int_0^{e^{-t}} g(au)du$ is small for all $t > T$ for sufficiently large T. Since g is continuous with $g(0) = 0$, given $\varepsilon > 0$, there exists $\delta > 0$ such that $|g(au)| < \varepsilon$ for $|au| < \delta$. Moreover, as $0 \le u \le e^{-t}$, we have $|au| = |a||u| \le |a|e^{-t}$. Thus we can choose $T > 0$ sufficiently large so that $|a|e^{-t} < \delta$ for $t > T$. Therefore $\left| e^t \int_0^{e^{-t}} g(au)du \right| < \varepsilon$. As this can be done for any $\varepsilon > 0$, we conclude that (6.7.4) holds. It follows that the stable manifold is

$$W^s(0, 0) = \{(x, y(x)) \in \mathbb{R}^2 : y(x) = - \int_0^1 g(xu)du\}.$$

Note that we could easily use L'Hospital's rule on $\lim_{t\uparrow\infty} e^t \int_0^{e^{-t}} g(xu)du$ to show that (6.7.4) holds. Next, we show that W^s is tangent to E^s:

$$\frac{dy}{dx}|_{x=0} = - \int_0^1 g'(xu)udu\Big|_{x=0}.$$

Making the substitution $v = xu$, this expression becomes

$$\frac{dy}{dx}|_{x=0} = - \frac{1}{x^2} \int_0^x g'(v)vdv\Big|_{x=0}.$$

Using L'Hospital's rule, we find the slope at the origin to be

$$- \frac{1}{x^2} \int_0^x g'(v)vdv\Big|_{x=0} = - \lim_{x\to 0} \frac{1}{x^2} \int_0^x g'(v)vdv = - \lim_{x\to 0} \frac{g'(x)x}{2x} = - \frac{1}{2} g'(0).$$

Thus W^s is tangent to E^s at the origin, and, moreover, $W^s \in C^1$.

Let $g(x) = xe^x$ in Example 6.20. Then $g(0) = 0$ and $g \in C^1$. Furthermore,

$$E^s = \{(x, y) \in \mathbb{R}^2 : y = - \frac{1}{2} g'(0)x\} = \{(x, y) \in \mathbb{R}^2 : y = - \frac{1}{2} x\},$$

and

$$y(x) = - \int_0^1 g(xu)du = \int_0^1 xue^{xu}du = -e^x + \frac{1}{x}e^x - \frac{1}{x}.$$

Copyright Elsevier 2022

Substitute the Maclaurin series for e^x into the last expression and simplify to get

$$y = \frac{-x}{2}\left(1 + \frac{2x}{3} + \frac{x^2}{3} + \cdots\right).$$

Thus

$$W^s(0,0) = \left\{(x, y(x)) \in \mathbb{R}^2 : y(x) = \frac{-x}{2}\left(1 + \frac{2x}{3} + \frac{x^2}{3}\right)\right\}.$$

In Example 6.20, we were able to compute the solutions to find W^s and W^u. This is not the case for most nonlinear systems. The next theorem affirms the existence of such manifolds in the neighborhoods of hyperbolic equilibrium solution, regardless of whether solutions can be found or not. We have seen that the stable manifold of a hyperbolic critical point is the collection of all states that asymptotically approach that fixed point as time goes to infinity. Knowing the stable and unstable manifolds of a fixed point can be useful for simple purposes, for example, for knowing which initial conditions of a system of ordinary differential equations lead to which asymptotic behavior. It is also very useful for spotting "exotic" behavior in dynamical systems.

As mentioned before, if the equilibrium solution is not the origin, then we use transformation so that it coincides with the origin. Next, we define the differentiability of manifolds.

Definition 6.7.3. (Homeomorphism) Let K_1 and K_2 be two subsets of a metric space X. Then K_1 and K_2 are said to be *homeomorphic* if there is a continuous one-to-one map $g : K_1 \to K_2$ such that g^{-1} is also continuous.

Such two sets are called *homeomorphic* or topologically equivalent if there is a homeomorphism of K_1 onto K_2.

Definition 6.7.4. (Differentiable manifold) An n-dimensional differentiable manifold M is a connected metric space with an open covering $M = \cup_\alpha U_\alpha$ such that

(1) for all α, $\cup_\alpha$ is homeomorphic to the open unit ball $B = \{x \in \mathbb{R}^n : |x| < 1\}$ in $\mathbb{R}^n$ centered at the origin, that is, for all α, there exists a homeomorphism $g_\alpha : U_\alpha \to B$ of U_α onto B, and

(2) if $U_\alpha \cap U_\beta \neq \emptyset$ and $g_\alpha : U_\alpha \to B$, $g_\beta : U_\beta \to B$ are homeomorphisms, then $g_\alpha\big(U_\alpha \cap U_\beta\big)$ and $g_\beta\big(U_\alpha \cap U_\beta\big)$ are subsets of $\mathbb{R}^n$, the map

$$g = g_\alpha \circ g_\beta^{-1} : g_\beta\big(U_\alpha \cap U_\beta\big) \to g_\alpha\big(U_\alpha \cap U_\beta\big)$$

is differentiable (or of class C^n), and for all $x \in g_\beta\big(U_\alpha \cap U_\beta\big)$, the Jacobian determinant is not zero, that is, $\det \frac{\partial g}{\partial x} \neq 0$.

For complete proof of the next theorem, we refer to [36].

Theorem 6.7.2. *Suppose* $f(0) = 0$ *and let* $E \subseteq \mathbb{R}^n$ *be an open subset containing the origin with* $f \in C^1(E)$. *Let* $\phi_t : E \to E$ *be the flow of* (6.7.1) *defined for all* $t \in \mathbb{R}$. *Let*

$$x' = Ax := Df(0)x. \tag{6.7.5}$$

Copyright Elsevier 2022

Suppose the linearized matrix $Df(0)$ has k eigenvalues with negative real parts and $n-k$ eigenvalues with positive real parts. Then there exists a k-dimensional differentiable manifold W^s that is tangent to the stable subspace E^s of (6.7.5)*, and there exists an $(n-k)$-dimensional differentiable manifold W^u that is tangent to the unstable space E^u of the linearized system* (6.7.5)*. Moreover,*

$$\lim_{t\uparrow\infty}\phi_t(p)=0 \ \textit{ for any } \ p\in W^s,$$

and

$$\lim_{t\downarrow-\infty}\phi_t(p)=0 \ \textit{ for any } \ p\in W^u.$$

Proof. (We only provide a sketch of the proof) This sketch of the proof is geared toward giving guidelines on how to find the stable and unstable manifolds.

Since $f\in C^1(E)$ and $f(0)=0$, we may write system (6.7.1) as

$$x'=Ax+F(x), \tag{6.7.6}$$

where $A=Df(0)$ and $F(x)=f(x)-Ax$ with $F\in C^1(E)$, $F(0)=0$ and $DF(0)=0$. There is an invertible $n\times n$ matrix C such that

$$B=C^{-1}AC=\begin{pmatrix}P & 0\\ 0 & Q\end{pmatrix},$$

where the $k\times k$ matrix P has the eigenvalues λ_i, $i=1,2,\dots,k$, each with negative real part, and the $(n-k)\times(n-k)$ matrix Q has the eigenvalues λ_i, $i=k+1,k+2,\dots,n$, each with a positive real part. Make the change of variables $y=C^{-1}x$. Then $x'=Ax+F(x)$ becomes $Cy'=ACy+F(Cy)$. Multiplying both sides from the left by C^{-1} gives $y'=C^{-1}ACy+C^{-1}F(Cy)$. Set $G(y)=C^{-1}F(Cy)$ to arrive at

$$y'=\begin{pmatrix}P & 0\\ 0 & Q\end{pmatrix}y+G(y). \tag{6.7.7}$$

Since each step we have made is reversible, solving system (6.7.7) is equivalent to solving the original system (6.7.6). Next, we labor to find stable and unstable manifolds. Define

$$U(t)=\begin{pmatrix}e^{Pt} & 0\\ 0 & 0\end{pmatrix} \quad\text{and}\quad V(t)=\begin{pmatrix}0 & 0\\ 0 & e^{Qt}\end{pmatrix},$$

so that

$$e^{\begin{pmatrix}P & 0\\ 0 & Q\end{pmatrix}t}=U(t)+V(t).$$

For $t\in\mathbb{R}$ and $a\in\mathbb{R}^n$, define the integral equation

$$u(t,a)=U(t)a+\int_0^t U(t-s)G(u(s,a))ds$$

Copyright Elsevier 2022

$$-\int_t^\infty V(t-s)G(u(s,a))ds. \tag{6.7.8}$$

Perko showed the integral equation (6.7.8) satisfies (6.7.7) and $\lim_{t\to\infty} u(t,a)=0$. Define the iterative scheme for computing the solution:

$$\begin{aligned}
u(t,a) &= 0,\\
u^{(k+1)}(t,a) &= U(t)a + \int_0^t U(t-s)G(u^{(k)}(s,a))ds\\
&\quad -\int_t^\infty V(t-s)G(u^{(k)}(s,a))ds.
\end{aligned}$$

Next, we give some insight on why this integral equation given by (6.7.8) is chosen.

In general, using the variation of parameters formula, the solution of (6.7.7) is

$$u(t,a) = \begin{pmatrix} e^{Pt} & 0 \\ 0 & e^{Qt} \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{P(t-s)} & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds.$$

Keep in mind that the goal is to remove the parts that blow up as $t \to \infty$. Thus we try to separate convergent and non-convergent parts from the above integral equation. Below we explain how this is done:

$$\begin{aligned}
u(t,a) &= \begin{pmatrix} e^{Pt} & 0 \\ 0 & e^{Qt} \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{P(t-s)} & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds\\
&= \begin{pmatrix} e^{Pt} & 0 \\ 0 & 0 \end{pmatrix} a + \begin{pmatrix} 0 & 0 \\ 0 & e^{Qt} \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{P(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u(s,a))ds\\
&\quad + \int_0^t \begin{pmatrix} 0 & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds\\
&= \begin{pmatrix} e^{Pt} & 0 \\ 0 & 0 \end{pmatrix} a + \begin{pmatrix} 0 & 0 \\ 0 & e^{Qt} \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{P(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u(s,a))ds\\
&\quad + \int_0^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds\\
&\quad - \int_t^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds \text{ (remove terms that blow up to get)}
\end{aligned}$$

Copyright Elsevier 2022

$$
\begin{aligned}
&= \begin{pmatrix} e^{Pt} & 0 \\ 0 & 0 \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{P(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u(s,a))ds \\
&- \int_t^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{Q(t-s)} \end{pmatrix} G(u(s,a))ds \\
&= U(t)a + \int_0^t U(t-s)G(u(s,a))ds - \int_t^\infty V(t-s)G(u(s,a))ds.
\end{aligned}
$$

It is evident that the last $n-k$ components of a do not enter the computation, and so we take them to be zero. As a consequence, let $u(t,a)$ be given by (6.7.8), and let us examine what that implies for the initial conditions $u(0,a)$. First, we notice that

$$
\begin{aligned}
&u_j(0,a) = a_j, \quad j = 1, 2, \dots, k, \\
&u_j(0,a) = -\Big(\int_0^\infty V(-s)G(u(s,a))ds \Big)_j, \quad j = k+1, \dots, n.
\end{aligned}
$$

Hence the last $n-k$ components of the initial conditions satisfy

$$a_j = \psi_j(a_1, \dots a_k) := u_j(0, a_1, \dots, a_k, 0 \dots, 0), \quad j = k+1, \dots, n.$$

Finally, the stable manifold $W^s(0)$ is defined by

$$W^s = \{(y_1, \dots, y_n) : y_j = \psi_j(y_1, \dots, y_k), \quad j = k+1, \dots, n\}.$$

Here is the iterative scheme for calculating an approximation to W^s:

(1) Calculate the approximate solution $u^{(m)}(t,a)$.

(2) For each $j = k+1, \dots, n$, the function $\psi_j(a_1, \dots, a_k)$ is given by the jth component of $u^{(m)}(0,a)$.

To find the unstable manifold W^u, do the same by replacing t by $-t$, that is,

$$y' = -By - G(y).$$

Then the stable manifold for this system will be the unstable manifold for (6.7.7). During the process, we must replace the vector y by the vector $(y_{k+1}, \dots, y_n, y_1, \dots, y_k)$ to determine the $(n-k)$-dimensional manifold W^u by the above process. □

We end this section with the following popular example.

Example 6.21. Consider the planar nonlinear system

$$
\begin{cases}
x_1' = -x_1 - x_2^2, \\
y' = x_1^2 + x_2
\end{cases}
$$

with the only equilibrium solution $(0,0)$. Then

Copyright Elsevier 2022

$$A = Df(0) = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}.$$

The eigenvalues of A are $\lambda = 1, -1$ with corresponding eigenvectors $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$ and $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$, respectively. Thus the matrix C is given by $C = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$. It follows that

$$A = B = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad F(x) = G(x) = \begin{pmatrix} -x_2^2 \\ x_1^2 \end{pmatrix},$$

and

$$U(t) = \begin{pmatrix} e^{-t} & 0 \\ 0 & 0 \end{pmatrix}, \quad V(t) = \begin{pmatrix} 0 & 0 \\ 0 & e^t \end{pmatrix}.$$

Since $n = 2$ and $k = 1$, the last components $n - k$ of the n vector a are zero. So we take $a = \begin{pmatrix} a_1 \\ 0 \end{pmatrix}$. Our goal is to find the first three successive approximations $u^{(1)}(t, a)$, $u^{(2)}(t, a)$, and $u^{(3)}(t, a)$ and use $u^{(3)}(t, a)$ to approximate the function ψ_2 describing the stable manifold $W^s : x_2 = \psi_2(x_1)$. Define the iterate of the function $u(t, a)$ using (6.7.8)

$$u^{(k+1)}(t, a) = \begin{pmatrix} e^{-t} & 0 \\ 0 & 0 \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{-(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u^{(k)}(s, a))ds$$
$$- \int_t^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{(t-s)} \end{pmatrix} G(u^{(k)}(s, a))ds,$$

where

$$u^{(0)}(t, a) = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$
$$u^{(1)}(t, a) = U(t)a = \begin{pmatrix} e^{-t}a_1 \\ 0 \end{pmatrix},$$

$$u^{(2)}(t, a) = \begin{pmatrix} e^{-t} & 0 \\ 0 & 0 \end{pmatrix} a + \int_0^t \begin{pmatrix} e^{-(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u^{(1)}(s, a))ds$$
$$- \int_t^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{(t-s)} \end{pmatrix} G(u^{(1)}(s, a))ds$$
$$= \begin{pmatrix} e^{-t}a_1 \\ 0 \end{pmatrix} - \int_t^\infty \begin{pmatrix} 0 \\ e^{(t-s)}e^{-2s}a_1^2 \end{pmatrix} ds = \begin{pmatrix} e^{-t}a_1 \\ -\frac{1}{3}e^{-2t}a_1^2 \end{pmatrix},$$

Copyright Elsevier 2022

$$
\begin{aligned}
u^{(3)}(t,a) &= \begin{pmatrix} e^{-t} & 0 \\ 0 & 0 \end{pmatrix} a - \int_0^t \begin{pmatrix} e^{-(t-s)} & 0 \\ 0 & 0 \end{pmatrix} G(u^{(2)}(s,a))ds \\
&\quad - \int_t^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{(t-s)} \end{pmatrix} G(u^{(2)}(s,a))ds \\
&= \begin{pmatrix} e^{-t}a_1 \\ 0 \end{pmatrix} - \int_0^t \begin{pmatrix} \frac{e^{-(t-s)}e^{42s}a_1^4}{9} \\ 0 \end{pmatrix} ds - \int_t^\infty \begin{pmatrix} 0 \\ e^{(t-s)}e^{-2s}a_1^2 \end{pmatrix} ds \\
&= \begin{pmatrix} e^{-t}a_1 + \frac{1}{27}(e^{-4t} - e^{-t})a_1^4 \\ -\frac{1}{3}e^{-2t}a_1^2 \end{pmatrix}.
\end{aligned}
$$

If we approximate $u(t,a)$ by $u^{(3)}(t,a)$, then

$$
u(t,a) = \begin{pmatrix} e^{-t}a_1 + \frac{1}{27}(e^{-4t} - e^{-t})a_1^4 \\ -\frac{1}{3}e^{-2t}a_1^2 \end{pmatrix} = \begin{pmatrix} u_1(t,a_1,0) \\ u_2(t,a_1,0) \end{pmatrix},
$$

and

$$
\psi_1(a_1) = u_1(0,a_1,0),\ \psi_2(a_1) = u_2(0,a_1,0)
$$

are approximated by

$$
\psi_1(a_1) = a_1, \quad \psi_2(a_1) = -\frac{1}{3}a_1^2.
$$

Thus the stable manifold is approximated by

$$
W^s = \{(y_1,y_2) \in \mathbb{R}^2 : y_2 = -\frac{1}{3}y_1^2\}.
$$

However, since the matrix $C = I$ for this example, the x and y spaces are the same. It follows that the stable manifold is given by

$$
W^s = \{(x_1,x_2) \in \mathbb{R}^2 : x_2 = -\frac{1}{3}x_1^2\}.
$$

The unstable manifold W^u can be found by applying the same procedure to the system with $t \to -t$ and x_1 and x_2 interchanged. Thus the stable manifold for the resulting system will be the unstable manifold for the original system. With this in mind, we arrive at the unstable manifold

$$
W^u = \{(x_1,x_2) \in \mathbb{R}^2 : x_1 = -\frac{1}{3}x_2^2\}.
$$

Remark 6.5. We used $u^{(3)}(t,a)$ to approximate $u(t,a)$, and so

$$
u(t,a) \approx \begin{pmatrix} e^{-t}a_1 + \frac{1}{27}(e^{-4t} - e^{-t})a_1^4 \\ -\frac{1}{3}e^{-2t}a_1^2 \end{pmatrix} \approx \begin{pmatrix} e^{-t}a_1 \\ -\frac{1}{3}e^{-2t}a_1^2 \end{pmatrix},
$$

Copyright Elsevier 2022

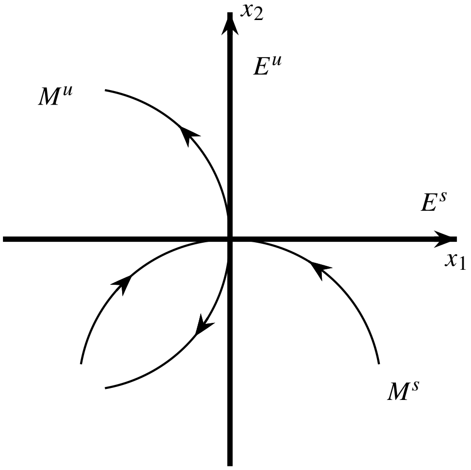

FIGURE 6.16

Local approximations of M^s and M^u of Example 6.21.

when $|a| = |(a_1, 0)^T|$ is small, or when a_1 is small. Thus the stable manifold can be approximated by

$$\begin{aligned}\psi_2(a_1) &= -\Big(\int_0^\infty V(-s)G(u(s,a))ds\Big)_2 \\ &= -\Big(\int_0^\infty \begin{pmatrix} 0 & 0 \\ 0 & e^{-s} \end{pmatrix} \begin{pmatrix} -\frac{1}{9}(e^{-4s} - e^{-t})a_1^4 \\ e^{-2s}a_1^2 \end{pmatrix} ds\Big)_2 \\ &= -\int_0^\infty e^{-s}e^{-2s}a_1^2 ds = -\frac{1}{3}a_1^2.\end{aligned}$$

Fig. 6.16 shows the stable and unstable manifolds in the neighborhood of (0, 0).

6.7.2 Global manifolds

The stable and unstable manifolds of Section 6.7.1 are local since they are defined in a small neighborhood of the origin. For that reason, they are referred to as the *local* stable and unstable manifolds at the origin. In this section, we define the *global manifolds* around the origin.

Definition 6.7.5. Let ϕ_t be the flow of (6.7.1). The *global stable* and *unstable manifolds* of (6.7.1) at the origin are defined by

$$G^s(0) = \cup_{t \le 0}\phi_t(W^s)$$

Copyright Elsevier 2022

and

$$G^u(0) = \cup_{t\geq 0}\phi_t(W^s),$$

respectively.

The global stable and unstable manifolds are unique and invariant with respect to the flow. Furthermore, for all $x \in G^s(0)$, $\lim_{t\to\infty}\phi_t(x) = 0$, and for all $x \in G^u(0)$, $\lim_{t\to-\infty}\phi_t(x) = 0$.

For the next theorem, we define a neighborhood around zero. Let $\delta > 0$. Define the neighborhood of the origin by

$$N_\delta(0) = \{x \in \mathbb{R}^n : ||x|| < \delta\}.$$

Theorem 6.7.3. *Assume that the hypotheses of Theorem 6.7.2 hold. Suppose the linearized matrix $Df(0)$ has k eigenvalues with negative real parts and $n-k$ eigenvalues with positive real parts. Set*

$$\mathrm{Re}(\lambda_j) < -\alpha < 0 < \beta < \mathrm{Re}(\lambda_m)$$

for $j = 1, \ldots, k$ and $m = k+1, \ldots, n$.

Then, given $\varepsilon > 0$, there exists $\delta > 0$ such that if $p \in N_\delta(0) \cap W^s$, then

$$|\phi_t(p)| \leq \varepsilon e^{-\alpha t}$$

for all $t \geq 0$. In a similar fashion, if $p \in N_\delta(0) \cap W^u$, then

$$|\phi_t(p)| \leq \varepsilon e^{\beta t}$$

for all $t \leq 0$.

Theorem 6.7.3 states that if solutions start in the stable manifold W^s, then they approach the origin exponentially. This is displayed in Example 6.19.

The center manifold theorem gives a detailed description of the dynamic of (6.7.1) in a neighborhood of a hyperbolic equilibrium once the center manifold W^c is determined.

6.7.3 Center manifold

Theorem 6.7.4. *Suppose $f(0) = 0$ and let $E \subseteq \mathbb{R}^n$ be an open subset containing the origin with $f \in C^1(E)$. Let $\phi_t : E \to E$ be the flow of (6.7.1) defined for all $t \in \mathbb{R}$. Let*

$$x' = Ax := Df(0)x. \tag{6.7.9}$$

Suppose the linearized matrix $Df(0)$ has k eigenvalues with negative real parts, j eigenvalues with positive real parts, and $m = n-k-j$ eigenvalues with zero real parts. Then there exists an m-dimensional differentiable manifold $W^c(0)$ that is

Copyright Elsevier 2022

tangent to the center subspace E^s of (6.7.9)*, a j-dimensional differentiable manifold $W^u(0)$ that is tangent to the unstable space E^u of the linearized system* (6.7.9)*, and an m-dimensional differentiable manifold W^c that is tangent to the center space E^c of the linearized system* (6.7.9)*. Moreover,*

$$\lim_{t\uparrow\infty}\phi_t(p)=0 \ \textit{ for any } \ p\in W^s,$$

$$\lim_{t\downarrow-\infty}\phi_t(p)=0 \ \textit{ for any } \ p\in W^u,$$

$$\lim_{t\downarrow-\infty}\phi_t(p)=0 \ \textit{ for any } \ p\in W^c.$$

In other words, the manifolds W^s, W^u, and W^c are invariant under the flow ϕ_t of (6.7.1).

Example 6.22. Consider the planar nonlinear system

$$\begin{cases} x_1' = x_1^2, \\ x_2' = -x_2 \end{cases}$$

with the only equilibrium solution $(0,0)$. Linearization around the equilibrium solution gives

$$A = Df(0) = \begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}.$$

The eigenvalues of A are $\lambda = 0, -1$ with corresponding eigenvectors $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$. Thus the stable subspace is $E^s = \{(x_1,x_2)\in\mathbb{R}^2 : x_1 = 0\}$, and the center subspace is $E^c = \{(x_1,x_2)\in\mathbb{R}^2 : x_2 = 0\}$. For constants c_1 and c_2, the system has the solution

$$x_1(t) = \frac{c_1}{1-c_1 t}, \quad x_2(t) = c_2 e^{-t}.$$

Note that if $c_1 = 0$, then $x_1 = 0$. Moreover, to get a better understanding of the dynamics of the solution, we eliminate t from both equations and arrive at the following relation between x_1 and x_2:

$$x_2 = c_2 e^{-\frac{1}{c_1}+\frac{1}{x_1}}.$$

Since $x_1 = 0$ for $c_1 = 0$, we have that the plane curves

$$x_2 = \Psi(x_1,c_1,c_2) = \begin{cases} c_2 e^{-\frac{1}{c_1}+\frac{1}{x_1}} & \text{for } x_1 < 0, \\ 0 & \text{for } x_1 = 0 \end{cases} \qquad (6.7.10)$$

Copyright Elsevier 2022

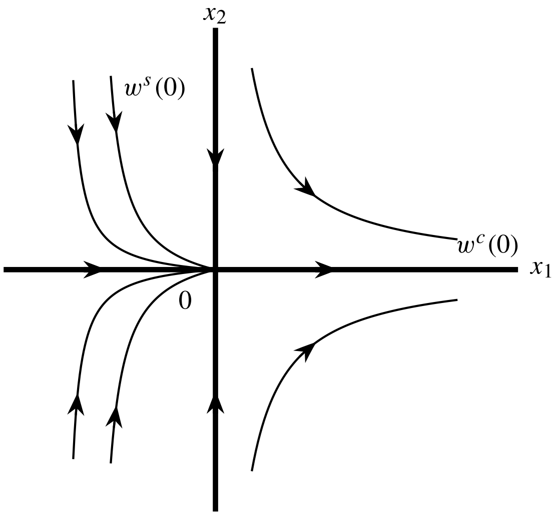

FIGURE 6.17

Center manifold.

satisfy

$$\Psi(0, c_1, c_2) = 0, \quad \frac{\partial \Psi}{\partial x_1}(0, c_1, c_2) = 0.$$

Now $c_1 < 0$ if and only if $x_1 < 0$ by $x_1(t) = \frac{c_1}{1-c_1 t}$ for all $t \geq 0$. It follows that when $x_1 < 0$ is sufficiently small, (6.7.10) is a local center manifold that is tangent to E^c at the origin. However, since (6.7.10) holds for any $c_1 < 0$ and c_2, there are infinitely many center manifolds, and all have the same orientations as seen in Fig. 6.17.

6.7.4 Center manifold and reduced systems

Let $E \subseteq \mathbb{R}^n$ contain the origin, and let $f : E \to \mathbb{R}^n$ be C^2. Consider the autonomous nonlinear differential equation

$$x' = f(x). \tag{6.7.11}$$

Since $f \in C^1(E)$ and $f(0) = 0$, we may write system (6.7.11) as

$$x' = Ax + F(x), \tag{6.7.12}$$

where $A = Df(0)$ and $F(x) = f(x) - Ax$ with $F \in C^1(E)$, $F(0) = 0$, and $DF(0) = 0$. There is an $n \times n$ invertible matrix C such that

$$C^{-1}AC = \begin{pmatrix} P & 0 \\ 0 & Q \end{pmatrix},$$

Copyright Elsevier 2022

where the $k \times k$ matrix P has eigenvalues λ_i, $i = 1, 2, \dots, k$, each with zero real part, and the $(n-k) \times (n-k)$ matrix Q has the eigenvalues λ_i, $i = k+1, k+2, \dots, n$, each with negative real part. Make the change of variables

$$\begin{pmatrix} y \\ z \end{pmatrix} = C^{-1}x, \quad y \in \mathbb{R}^k, \quad z \in \mathbb{R}^{n-k}$$

and transform (6.7.12) into the form

$$\begin{aligned} y' &= Px + F_1(y, z), \\ z' &= Qz + F_2(y, z), \end{aligned} \tag{6.7.13}$$

where

$$F_i(0,0) = 0, \ \frac{\partial F_i}{\partial y}(0,0) = \frac{\partial F_i}{\partial z}(0,0), \quad i = 1, 2.$$

If $z = h(y)$ is an invariant manifold for (6.7.13) with

$$h(0) = 0 \ \text{ and } \ \frac{\partial h}{\partial y}(0) = 0, \tag{6.7.14}$$

then we define the local *center manifold*

$$W^c = \{(y, z) \in \mathbb{R}^k \times \mathbb{R}^{n-k} : y = h(y), \ \ ||y|| < \delta\}$$

for small $\delta > 0$. This way, W^c is tangent to E^c at the origin. We have the following theorem.

Theorem 6.7.5. *For system* (6.7.13)*, there exist* $\delta > 0$ *and* $h \in C^1$ *with* $h(y)$ *defined for all* $||y|| < \delta$ *such that* $z = h(y)$ *is a center manifold.*

On the center manifold W^c, we get the *reduced system*

$$y' = Px + F_1(y, h(y)),$$

and z' can be calculated on the center manifold in two ways: directly from the z' equation above or by differentiating $z = h(y)$, that is,

$$z' = Qz + F_2(y, h(y)) \ \text{ and } \ z' = \frac{d}{dt}h(y) = Dh(y)y' = Dh(y)[Px + F_1(y, h(y))],$$

where $Dh(y)$ is the matrix formed by partial derivatives of $h(y)$. Note that in one dimension, $Dh(y) = h'(y)$. Expanding h as a Taylor series (noting that the constant and linear terms vanish), the two equations for z' provide two different polynomials, and the coefficients of different monomials can be equated to determine the coefficients of the Taylor expansion. We end the section with the following two examples.

Copyright Elsevier 2022

Example 6.23. Consider the planar nonlinear system

$$\begin{cases} x' = xy, \\ y' = -x^2 - y \end{cases}$$

with the only equilibrium solution $(0, 0)$. Linearization around the equilibrium solution gives

$$A = Df(0) = \begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}.$$

The eigenvalues of A are $\lambda = 0, -1$ with corresponding eigenvectors $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$. Thus the stable subspace is $E^s = \{(x, y) \in \mathbb{R}^2 : x = 0\}$, and the center subspace is $E^c = \{(x, y) \in \mathbb{R}^2 : y = 0\}$. Since the matrix A is already in normal form, no coordinate transformation is needed. We consider a center manifold of the form

$$y = h(x) = ax^2 + bx^3 + cx^4 + \mathscr{O}(x^5). \tag{6.7.15}$$

There is no constant term and no linear term in $h(x)$ since the center manifold passes through the origin and should be tangent to E^c. Now we calculate the constants. We have

$$y' = -x^2 - y = -x^2 - \left(ax^2 + bx^3 + cx^4\right) + \mathscr{O}(x^5). \tag{6.7.16}$$

Next, we differentiate (6.7.15) with respect to t. Using the chain rules, we get $y' = \dfrac{dh(x)}{dt} = x'h'(x)$ or

$$y' = x'h'(x) = xyh'(x) = x\left(ax^2 + bx^3 + cx^4 + \ldots\right)\left(2ax + 3bx^2 + 4cx^3 + \ldots\right). \tag{6.7.17}$$

Setting the right side of (6.7.17) equal to (6.7.16) and equating the coefficients at x^2, x^3, and x^4 give

$$a = -1, \quad b = 0, \quad \text{and} \quad c = -2.$$

Thus the center manifold is given by

$$W^c = \{(x, y) \in \mathbb{R}^2 : y = -x^2 - 2x^4\},$$

and the dynamics on W^c is

$$x' = xh(x) = -x^3 - 2x^5 + \mathscr{O}(x^7).$$

Now for $x > 0$, we have $x' < 0$ and $x' > 0$ if $x < 0$. Thus the origin is stable, and the solutions are stable nodes as shown in the graph below, but the motion onto the center manifold in the y-direction is much faster than the motion on the center manifold, leading to a phase portrait shown in Fig. 6.18.

Copyright Elsevier 2022

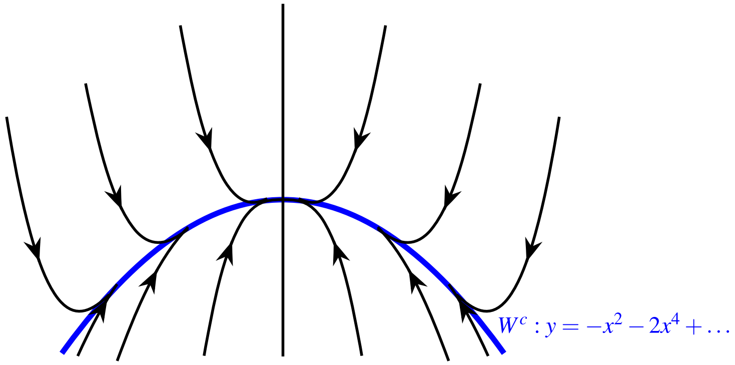

FIGURE 6.18

Exponential collapse of trajectories onto the center manifold and then slow convergence toward $(0, 0)$ on the center manifold.

The next example shows the need for a transformation.

Example 6.24. Consider the planar nonlinear system

$$\begin{cases} x' = y - x + xy, \\ y' = x - y - x^2 \end{cases} \tag{6.7.18}$$

with the only equilibrium solution $(0, 0)$. Linearization around the equilibrium solution gives

$$A = Df(0) = \begin{pmatrix} -1 & 1 \\ 1 & -1 \end{pmatrix}.$$

The eigenvalues of A are $\lambda = 0, -2$ with corresponding eigenvectors $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $\begin{pmatrix} -1 \\ 1 \end{pmatrix}$. Thus the stable subspace is $E^s = \{(x, y) \in \mathbb{R}^2 : y = -x\}$, and the center subspace is $E^c = \{(x, y) \in \mathbb{R}^2 : y = x\}$.

Let $C = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$. Then $C^{-1} = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$. Make the change of variable from x, y coordinates to u, v coordinates by

$$\begin{pmatrix} u \\ v \end{pmatrix} = C^{-1} \begin{pmatrix} x \\ y \end{pmatrix} = \frac{1}{2} \begin{pmatrix} x + y \\ y - x \end{pmatrix}$$

or

$$\begin{pmatrix} x \\ y \end{pmatrix} = C \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} u - v \\ u + v \end{pmatrix}.$$

Copyright Elsevier 2022

Under these transformations, system (6.7.18) in the u, v coordinates becomes

$$u' = uv - v^2, \quad v' = -2v + uv - u^2.$$

The new system is now in the normal form since

$$Df(0) = \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix}.$$

For similar reasons as in the above example, we define the center manifold $h(u)$ by

$$v(u) = h(u) = au^2 + bu^3 + cu^4 + \cdots .$$

Then using the chain rule, we arrive at

$$\begin{aligned} v' &= \left[2au + 3b^2u^2 + 4cu^3 + \dots\right]u' \\ &= \left[2au + 3b^2u^2 + 4cu^3 + \dots\right] \\ &\times \left[u\left(au^2 + bu^3 + cu^4 + \dots\right) - \left(au^2 + bu^3 + cu^4 + \dots\right)^2\right] \\ &= 2a^2u^4 + (5ab - 2a^3)u^5 + \cdots . \end{aligned} \tag{6.7.19}$$

On the other hand, using the second equation of the system with $v = h(u)$ gives

$$\begin{aligned} v' &= -2v + uv - u^2 \\ &= -2\left(au^2 + bu^3 + cu^4 + \dots\right) + u\left(au^2 + bu^3 + cu^4 + \dots\right) - u^2 \\ &= (2a + 1)u^2 + (2b - a)u^3 + (3c - b)u^4 + \cdots . \end{aligned} \tag{6.7.20}$$

Setting (6.7.19) equal to (6.7.20) and then equating the coefficients at u^2, u^3, and u^4 give

$$a = -\frac{1}{2}, \quad b = -\frac{1}{4}, \quad c = -\frac{3}{8},$$

and it follows that the center manifold in uv coordinates is

$$W^c = \{(u, v) \in \mathbb{R}^2 : v = -\frac{1}{2}u^2 - \frac{1}{4}u^3 - \frac{3}{8}u^4 + \dots\}.$$

The dynamics on the center manifold is

$$u' = uv - v^2 = -\frac{1}{2}u^3 - \frac{1}{4}u^4 - \frac{3}{8}u^5 + \cdots ,$$

which is stable for small u. Finally, the center manifold W^c in the original coordinates x, y is approximated from replacing u with $x + y$ and v with $y - x$:

$$W^c = \left\{(x, y) \in \mathbb{R}^2 : y - x = -\frac{1}{4}(x + y)^2 - \frac{1}{16}(x + y)^3 - \frac{3}{64}(x + y)^4 + \dots\right\}.$$

Copyright Elsevier 2022

6.7.5 Hartman–Grobman theorem

Consider the nonlinear autonomous system

$$x' = f(x), \tag{6.7.21}$$

where $E \subseteq \mathbb{R}^n$, and $f : E \to \mathbb{R}^n$ is a C^2 function. The *Hartman–Grobman theorem* states that near a hyperbolic equilibrium solution x_0, the nonlinear system given by (6.7.21) has the same qualitative structures as the linearized system

$$x' = Ax, \tag{6.7.22}$$

where $A = Df(x_0)$. In this section, we assume that x_0 is the origin, $E \subseteq \mathbb{R}^n$ contains the origin, and $f(0) = 0$. Recall from Definition 6.7.3 that two sets K_1 and K_2 are said to be *homeomorphic* if there is a continuous one-to-one map $g : K_1 \to K_2$ such that g^{-1} is also continuous.

In our case the two autonomous systems (6.7.21) and (6.7.22) are said to be topologically equivalent in a neighborhood of the origin or to have the same qualitative structure near the origin if there is a homeomorphism H mapping an open set U containing the origin onto an open set V containing the origin that maps trajectories of (6.7.21) in U onto trajectories (6.7.22) in V and preserves the orientation. If the homeomorphism H preserves parameterization by time t, then (6.7.21) and (6.7.22) are said to be topologically conjugate in the neighborhood of the origin.

We have the following example.

Example 6.25. Consider the two linear systems $x' = Ax$ and $y' = By$ with

$$A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \text{ and } B = \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}.$$

Define

$$R = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}; \text{ then } R^{-1} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

It is easy to verify that $B = RAR^{-1}$. Let $y = H(x) = Rx$ or $x = R^{-1}y$. Then it follows that

$$y' = RAR^{-1}y = By.$$

Suppose $x(0) = x_0$. Then $x(t) = e^{At}x_0$ is the solution of $x' = Ax$, $x(0) = x_0$. Similarly, if $y(0) = y_0$, then $y = e^{Bt}y_0$ with $y_0 = Rx_0$.

Then by (3.4.3) it follows that

$$y(t) = H(x(t)) = Rx(t) = Re^{At}x_0 = Re^{At}R^{-1}y_0 = e^{Bt}y_0 = e^{Bt}Rx_0$$

is the solution of $x' = Bx$. In other words, H maps the trajectories of $x' = Ax$ onto trajectories of $x' = Bx$ and preserves the parameterization by t since

$$He^{At} = e^{Bt}H.$$

Copyright Elsevier 2022

Thus H is a homeomorphism, and $x' = Ax$ and $y' = By$ are topologically conjugate.

Next, we introduce the Hartman–Grobman theorem, proved independently by Grobman in 1959 and Hartman in 1960. We only offer an outline of the proof, which should serve as guidelines on how to find the homeomorphism H. For complete proof, we refer the reader to [26] or [33]. In plain language the theorem says that if the linearization matrix has no zero or purely imaginary eigenvalues, then the phase portrait for the nonlinear system near an equilibrium point is similar to that of its linearization.

Theorem 6.7.6. *(Hartman–Grobman theorem) Let $f(0) = 0$, and let $E \subseteq \mathbb{R}^n$ be an open subset containing the origin with $f \in C^1(E)$. Let ϕ_t be the flow of (6.7.21). Suppose the linearized matrix $Df(0)$ has no eigenvalue with zero real part (the origin is hyperbolic). Then there is a homeomorphism H mapping an open set U containing the origin onto an open set V containing the origin such that for each $x_0 \in U$, there is an open interval $I_0 \subseteq \mathbb{R}$ containing zero such that for all $x_0 \in U$ and $t \in I_0$, we have*

$$H \circ \phi_t(x_0) = e^{At} H(x_0).$$

In other words, H maps trajectories of (6.7.21) in U onto trajectories (6.7.22) in V and preserves the orientation and parameterization by time t.

Proof. (Outline) Suppose that

$$A = Df(0) = \begin{pmatrix} P & 0 \\ 0 & Q \end{pmatrix},$$

where all the eigenvalues of the matrix P have negative real parts and all the eigenvalues of the matrix Q have positive real parts. Let

$$x_0 = \begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \in \mathbb{R}^n,$$

let ϕ_t be the flow of (6.7.21) and write the solution

$$x(t, x_0) = \phi_t(x_0) = \begin{pmatrix} y(t, y_0, z_0) \\ z(t, y_0, z_0) \end{pmatrix}$$

for y_0 and z_0 in E^s and E^u, respectively.

Define locally ($t = 1$) the transformation

$$T^1 x_0 = \begin{pmatrix} e^P y_0 + Y(x_0) \\ e^Q z_0 + Z(x_0) \end{pmatrix}.$$

Now for $x \in \mathbb{R}^n$, define

$$H_0(x) = \begin{pmatrix} \Phi(x) \\ \Psi(x) \end{pmatrix} = \begin{pmatrix} \Phi(y, z) \\ \Psi(y, z) \end{pmatrix}.$$

Copyright Elsevier 2022

Then

$$H_0 \circ T^1 = e^A \circ H_0,$$

which component-wise is equivalent to

$$\begin{aligned} e^P \Phi(x) &= \Phi(e^P y + Y(x), e^Q z + Z(x)), \\ e^Q \Psi(x) &= \Phi(e^P y + Y(x), e^Q z + Z(x)). \end{aligned} \tag{6.7.23}$$

Next, we define a continuous successive approximation from the second equation by

$$\begin{cases} \Psi_0(x) = z, \\ \Psi_{k+1}(x) = e^{-Q}\Phi_k(e^P y + Y(x), e^Q z + Z(x)), \ k = 0, 1, \dots. \end{cases}$$

Then $\Psi_k(x)$ is a Cauchy sequence of continuous functions, which converges uniformly as $k \to \infty$ to a continuous function $\Psi(x)$. We write the first equation in (6.7.23) by

$$e^{-P}\Phi(x) = \Phi(e^{-P} y + Y_1(x), e^{-Q} z + Z_1(x)), \tag{6.7.24}$$

where the functions Y_1 and Z_1 are defined by the inverse of T,

$$T^{-1}(y, z) = \begin{pmatrix} e^{-P} y + Y_1(y, z) \\ e^{-Q} z + Z_1(y, z) \end{pmatrix}.$$

With this setup, Eq. (6.7.24) can be solved by the method of successive approximations exactly as above with $\Phi_0(x) = y$. Finally, define the homeomorphism

$$H = \int_0^1 e^{-As} H_0 T^s ds = \int_0^1 e^{-As} H_0 \circ \phi_s(x, y) ds,$$

which satisfies

$$H \circ \phi_t(x, y) = e^{At} H(x, y).$$ □

Remark 6.6. (1) From the computational aspect, Theorem 6.7.6 is difficult to use since it requires the computation of the flow, which is not possible in most nonlinear systems.
(2) However, conceptually, it suffices to know that such a homeomorphism exists. This allows us to understand the dynamics of the nonlinear system near a hyperbolic equilibrium solution by simply looking at the eigenvalues of the linear system $x' = Ax$, $A = Df(0)$, obtained from linearizing the nonlinear system near the origin.

In the next example, we consider a system for which the flows can be computed.

Example 6.26. Consider

$$\begin{cases} y' = -y, \\ z' = z + y^2 \end{cases}$$

Copyright Elsevier 2022

with

$$x(0)=\begin{pmatrix}y_0\\ z_0\end{pmatrix},$$

$$Df(0)=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},$$

and hence $e^P=e^{-1}$, and $e^Q=e$. The equation $y'=-y$ has the solution $y=y_0e^{-t}$. Substituting this solution into the second differential equation and using the variation of parameters formula, we arrive at

$$z=z_0e^t+\frac{1}{3}y_0^2(e^t-e^{-2t}).$$

Thus

$$\phi_t(x_0)=\begin{pmatrix}y_0e^{-t}\\ z_0e^t+\frac{1}{3}y_0^2(e^t-e^{-2t})\end{pmatrix},$$

and at $t=1$, $Y(x)=0$, $Z(x)=\frac{1}{3}y_0^2(e-e^{-2})$, where $x=(y,z)$. As a consequence,

$$e^Q\Psi(x)=\Phi(e^Py+Y(x),e^Qz+Z(x)),$$

which results in

$$e\Psi(x)=\Phi(e^{-1}y,ez+\frac{1}{3}y_0^2(e-e^{-2})).$$

Therefore the successive approximations are given by

$$\Psi_0(x)=z,\quad x=(y,z)\in\mathbb{R}^2,$$

$$\begin{aligned}\Psi_1(x)&=e^{-1}\Psi_0(e^{-1}y,ez+\frac{1}{3}y^2(e-e^{-2}))\\ &=e^{-1}[ez+\frac{1}{3}y^2(e-e^{-2})]\\ &=z+\frac{1}{3}(1-e^{-3})y^2,\end{aligned}$$

$$\begin{aligned}\Psi_2(x)&=e^{-1}\Psi_1(e^{-1}y,ez+\frac{1}{3}(e-e^{-2})y^2)\\ &=e^{-1}[(ez+\frac{1}{3}(e-e^{-2})y^2+\frac{1}{3}(1-e^{-3})e^{-2}y^2]\\ &=z+\frac{1}{3}(1-e^{-3})(y^2+e^{-3}y^2)\\ &=z+\frac{1}{3}(1-e^{-3})(1+e^{-3})y^2,\end{aligned}$$

Copyright Elsevier 2022

$$\begin{aligned}
\Psi_3(x) &= e^{-1}\Psi_2(e^{-1}y, ez + \frac{1}{3}(e - e^{-2})y^2) \\
&= e^{-1}[(ez + \frac{1}{3}(e - e^{-2})y^2 + \frac{1}{3}(1 - e^{-3})(1 + e^{-3})e^{-2}y^2] \\
&= z + \frac{1}{3}(1 - e^{-3})(y^2 + e^{-3}y^2) \\
&= z + \frac{1}{3}(1 - e^{-3})(1 + e^{-3} + e^{-6})y^2, \\
&\dots
\end{aligned}$$

$$\begin{aligned}
\Psi_m(x) &= z + \frac{1}{3}(1 - e^{-3})(1 + e^{-3} + e^{-6} + \ldots + (e^{-3})^{m-1})y^2 \\
&= z + \frac{1}{3}(1 - e^{-3})y^2 \sum_{n=1}^{m} (\frac{1}{e^3})^{n-1} \to z + \frac{1}{3}(1 - e^{-3})\frac{1}{1 - e^{-3}}y^2 \\
&= z + \frac{1}{3}y^2 \text{ as } m \to \infty.
\end{aligned}$$

Thus as $m \to \infty$,

$$\Psi_m(y,z) \to \Psi(y,z) = z + \frac{1}{3}y^2$$

uniformly for all $(y,z) \in \mathbb{R}^2$. Now the functions Y_1 and Z_1 are defined by the inverse of T,

$$T^{-1}(y,z) = \begin{pmatrix} e^{-P}y + Y_1(y,z) \\ e^{-Q}z + Z_1(y,z) \end{pmatrix}.$$

However,

$$T^{-1}(y,z) = \begin{pmatrix} ey \\ e^{-1}z - e\frac{e^3-1}{3e^2}y^2 \end{pmatrix},$$

which implies that $Y_1(y,z) = 0$ and $Z_1(y,z) = -ery^2$, where $r = \frac{e^3-1}{3e^2}$. To fully determine $\Phi(y,z)$, we use (6.7.24):

$$e^{-P}\Phi(x) = \Phi(e^{-P}y + Y_1(x), e^{-Q}z + Z_1(x))$$

or

$$e\Phi(x) = \Phi(ey, e^{-1}z - ery^2).$$

We define the successive approximations by

$$\begin{gathered}
\Phi_0(y,z) = y, \\
\Phi_{k+1}(y,z) = e^{-1}\Phi_k(ey, e^{-1}z - ery^2), \ k = 0, 1, \ldots,
\end{gathered}$$

Copyright Elsevier 2022

and get

$$\Phi(y,z)=y,\ \ (y,z)\in\mathbb{R}^2.$$

Thus

$$H_0(y,z)=\begin{pmatrix} y \\ z+\frac{1}{3}y^2 \end{pmatrix},$$

and the homeomorphism H is given by

$$\begin{aligned} H(y,z) &= \int_0^1 e^{-As}H_0T^s ds \\ &= \int_0^1 \begin{pmatrix} e^s & 0 \\ 0 & e^{-s} \end{pmatrix} H_0[\begin{pmatrix} ye^{-s} \\ ze^s+\frac{1}{3}y^2(e^s-e^{-2s}) \end{pmatrix}]ds \\ &= \int_0^1 \begin{pmatrix} e^s & 0 \\ 0 & e^{-s} \end{pmatrix} \begin{pmatrix} ye^{-s} \\ ze^s+\frac{1}{3}y^2(e^s-e^{-2s})+\frac{1}{3}y^2e^{-2s} \end{pmatrix} ds \\ &= \begin{pmatrix} y \\ z+\frac{1}{3}y^2 \end{pmatrix}. \end{aligned}$$

Note that H_0T^s is taken as the composition or H_0 is acting on T^s. Let's dig deeper and see what subset gets mapped onto the stable subspace E^s. Looking at the corresponding eigenvector of $\lambda=-1$, we see that $E^s=\{(y,z)\in\mathbb{R}^2 : z=0\}$. We are interested in finding the subset such that

$$H(y,z)=\begin{pmatrix} y \\ z+\frac{1}{3}y^2 \end{pmatrix}\in E^s.$$

It readily follows that the subset is

$$\{(y,z)\in\mathbb{R}^2 : z=-\frac{1}{3}y^2\},$$

which is the stable manifold W^s by simply taking $t\to\infty$ in the flow. In other words, the homeomorphism H maps W^s onto E^s. In addition, H maps $W^u=\{(y,z)\in\mathbb{R}^2 : y=0\}$ onto $E^u=\{(y,z)\in\mathbb{R}^2 : y=0\}$. Solving the linearized system $y'=-y$, $z'=z$, we get $y=c_1e^{-t}$ and $z=c_2e^t$ or $z=\frac{c}{y}$ for constants c_1, c_2, and c. Thus

$$H(y,z)=H(y,\frac{c}{y}),$$

from which it follows that

$$(y,z+\frac{1}{3}y^2)=(y,\frac{c}{y}).$$

Copyright Elsevier 2022

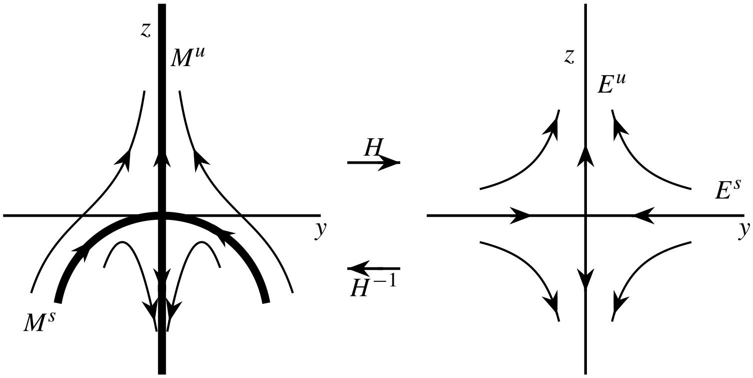

FIGURE 6.19

Under the homeomorphism H, the phase portrait for the nonlinear system near the origin is similar to that of its linearization.

Thus

$$z = \frac{c}{y} - \frac{1}{3}y^2.$$

We just showed that, under H, the curve $z = \frac{c}{y} - \frac{1}{3}y^2$ of the nonlinear system gets mapped onto $z = \frac{c}{y}$ of the linearized system. (See Fig. 6.19.)

6.8 Exercises

Exercise 6.1. For the following equations, find the equilibrium solutions, sketch the phase line, and determine the type of stability of all the equilibria.
(a) $x' = x^2(4 - x)$.
(b) $x' = 2x(1 - x) - \frac{1}{2}x$.
(c) $x' = (4 - x)(2 - x)^3$.

Exercise 6.2. Find the equilibrium solutions in terms of the parameter μ and determine their stability. Show that the origin is a turning point and sketch a bifurcation diagram and label all branches as stable or unstable. When possible, identify the type of bifurcation.
(a) $x' = \mu x(1 - x)$.
(b) $x' = (x^2 - \mu)(1 - x)$.

Exercise 6.3. Find the equilibrium solutions, determine their stability, and show that the origin is a turning point and sketch the bifurcation diagram.

$$x' = \mu - x^2.$$

Copyright Elsevier 2022

Exercise 6.4. For the following equations, show that each of them undergoes a transcritical bifurcation and find the bifurcation value. Sketch the bifurcation diagram.
(a) $x' = \mu x + 2x^2$.
(b) $x' = (2+\mu)x - 5x^2$.

Exercise 6.5. Find the equilibrium solution x_0 at μ_0 and use Theorem 6.1.2 to determine the type of bifurcation at (x_0, μ_0) for the scalar system

$$x' = \mu + x - e^x + 1.$$

Exercise 6.6. Show that

$$x' = \mu x + x^3$$

undergoes a pitchfork bifurcation at $\mu = 0$ and sketch the bifurcation diagram.

Exercise 6.7. Complete the proof of Theorem 6.2.1, that is, show that inequality (6.2.8) holds on $[0, \infty)$.

Exercise 6.8. Suppose the origin is uniformly stable for the linear system $x' = A(t)x$, where $A(t)$ is an $n \times n$ matrix with continuous entries. Suppose that $F : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^n$ is continuous with

$$|F(t,x)| \le \gamma(t)|x| \text{ and } \int_0^\infty \gamma(t)dt < \infty,$$

where the function $\gamma(t) > 0$ is continuous. Show that if $F(t, 0) = 0$, then the zero solution of

$$x' = A(t)x + F(t,x),$$

is uniformly stable.

Exercise 6.9. Investigate the stability of each of the equilibrium points for the given systems:
(a) $x' = x - 3y + 2xy$, $y' = 4x - 6y - xy$.
(b) $x' = 6x - 5y + x^2$, $y' = 2x - y + y^2$.
(c) $x' = x - 2y + 3xy$, $y' = 2x - 3y - x^2 - y^2$.
(d) $x' = x - y$, $y' = x^2 - y$.
(e) $x' = y^2 - 1$, $y' = x^3 - y$.
(f) $x' = 8x - y^2$, $y' = -y + x^2$.

Exercise 6.10. Consider the system

$$x' = -x + hy,$$
$$y' = x - y.$$

Show that

Copyright Elsevier 2022

(1) $(0, 0)$ is asymptotically stable if $h = 0$,
(2) $(0, 0)$ is asymptotically stable spiral if $h < 0$, and
(3) $(0, 0)$ asymptotically stable node if $0 < h < 1$.

Exercise 6.11. Study the stability of the origin for the system

$$\begin{aligned} x' &= y + hx(x^2 + y^2), \\ y' &= -x + hy(x^2 + y^2). \end{aligned}$$

(Hint: use polar coordinates.)

Exercise 6.12. Study the stability of the origin for the system

$$\begin{aligned} x' &= -2x - y + x^2 y, \\ y' &= 4x + \mu y - y^2 \end{aligned}$$

for $\mu \neq 2$.

Exercise 6.13. Use polar coordinates to study the stability of the origin for the system

$$x' = -y - x\sqrt{x^2 + y^2}, \quad y' = x - y\sqrt{x^2 + y^2}.$$

Exercise 6.14. Show that the system

$$x' = y + \frac{x(1 - x^2 - y^2)}{\sqrt{x^2 + y^2}}, \quad y' = -x + \frac{y(1 - x^2 - y^2)}{\sqrt{x^2 + y^2}}$$

has a limit cycle.

Exercise 6.15. Show that the system

$$x' = y + x(1 - x^2 - y^2), \quad y' = -x + y(1 - x^2 - y^2)$$

has a limit cycle.

Exercise 6.16. Consider the system

$$\begin{aligned} x' &= 4x + 4y - x(x^2 + y^2), \\ y' &= -4x + 4y - y(x^2 + y^2). \end{aligned}$$

(a) Show that there is a closed path in the region $1 \leq r \leq 3$, where $r^2 = x^2 + y^2$.
(b) Find the general solution.

Exercise 6.17. Show that $x'' + x' + f(x) = 0$ has no periodic solution.

Exercise 6.18. Determine the region on which there is no periodic solution for

$$x'' + \beta(x^2 - 1)x' + x = 0.$$

Copyright Elsevier 2022

Exercise 6.19. Consider the predator–prey model

$$x' = x((1-x)-y), \quad y' = y(x-a),\ a>0,$$

where $x(t)$ and $y(t)$ are the numbers of preys and predators at time t, respectively.
(a) Sketch the nullclines and indicate the direction field.
(b) Find and analyze the equilibrium points.
(c) What can you say for each of the cases $a>1$, $a=1/2$, and $0<a<1$?

Exercise 6.20. (a) Prove Theorem 6.4.2.
(b) Use (a) to show that the system

$$x' = x(A-ax+by), \quad y' = y(B-cy+dx),$$

where a, b, c, d, A, and B are constants with $a,\ c>0$, has no closed trajectories or periodic orbits.
(Hint: let $h(x,y)=\frac{1}{xy}$.)

Exercise 6.21. Use polar coordinates to study the stability of the origin for the system

$$x' = -x - \frac{y}{\mathrm{Ln}(\sqrt{x^2+y^2})}, \quad y' = -y + \frac{x}{\mathrm{Ln}(\sqrt{x^2+y^2})}.$$

Exercise 6.22. Consider the nonlinear system

$$x' = y + \frac{1}{4}x[1-2(x^2+y^2)], \quad y' = -x + \frac{1}{2}y[1-(x^2+y^2)].$$

(a) Show that $(0,0)$ is the only critical point.
(b) Show, using polar coordinates (r,θ), that

$$rr' = \frac{1}{4}r^2[1+\sin^2(\theta)] - \frac{1}{2}r^4.$$

(c) Find the region R of Theorem 6.4.4.

Exercise 6.23. Consider the nonlinear system

$$x' = x-y-x^3, \quad y' = x+y-y^3.$$

Given that $(0,0)$ is the only critical point, use polar coordinates to show that there is a limit cycle in the region

$$R = \{(r,\theta) : 1<r<\sqrt{2}\}.$$

Exercise 6.24. Use Theorem 6.6.1 to show that the system

$$x' = x\mu - y - x^3 - xy^2 - y, \quad y' = x + y\mu - y^3 - x^2y$$

undergoes a Hopf bifurcation, that is, the system has a stable periodic solution with radius $\sqrt{\mu}$.

Copyright Elsevier 2022

Exercise 6.25. Decide if Theorem 6.6.1 applies to the van der Pol equation given in system form by

$$x' = y, \quad y' = -x - \mu(x^2 - 1)y.$$

Exercise 6.26. By solving each of the systems below find E^s, E^u, M^s, and M^u.
(a) $x' = -2x$, $y' = 3x + y$.
(b) $x' = 2x - y$, $y' = -y$.

Exercise 6.27. By solving the following system find E^s, E^u, M^s, and M^u:

$$x_1' = -x_1, \quad x_2' = x_2 + x_1^2, \quad x_3' = 0.$$

Exercise 6.28. Use the method of Example 6.21 to find M^s and M^u for

$$x_1' = -x_1, \quad x_2' = 2x_2 + x_1^2.$$

Exercise 6.29. Use the method of Example 6.21 to find M^s and M^u for

$$x_1' = -x_1 - x_2^3, \quad x_2' = x_2 + x_1^3.$$

(Hint: Find the first four successive approximations to $u^{(1)}(t,a)$, $u^{(2)}(t,a)$, $u^{(3)}(t,a)$, $u^{(4)}(t,a)$.)

Exercise 6.30. In Example 6.23, find the center manifold using

$$y = h(x) = ax^2 + bx^3 + cx^4 + dx^5 + ex^6 + \mathcal{O}(x^7).$$

Exercise 6.31. Find the center manifold W^c of the system

$$\begin{cases} x' = x^2 y, \\ y' = -x^2 - y. \end{cases}$$

Exercise 6.32. Find the center manifold W^c of the system

$$\begin{cases} x' = x + 2y - xy, \\ y' = 2x + 4y - y^2. \end{cases}$$

Exercise 6.33. For Example 6.26, verify that

$$e^{At} H(y,z) = H \circ \phi_t(x,y).$$

Exercise 6.34. Find the homeomorphism H for the nonlinear system

$$\begin{cases} y' = y + z^2, \\ z' = -z. \end{cases}$$

Copyright Elsevier 2022

Exercise 6.35. Approximate the homeomorphism H, W^s, and W^u for the nonlinear system

$$\begin{cases} y_1' = -y_1, \\ y_2' = -y_2^2 + y_1^3, \\ z' = z + y_1^3. \end{cases}$$

Exercise 6.36. Consider the two linear systems $x' = Ax$ and $y' = By$ with

$$A = \begin{pmatrix} -3 & 0 \\ 0 & 1 \end{pmatrix} \text{ and } B = \begin{pmatrix} -1 & -2 \\ -2 & -1 \end{pmatrix}.$$

Find the homeomorphism H so that $e^{tA}H = He^{tB}$.

CHAPTER 7

Lyapunov functions

Lyapunov functions are named after Aleksandr Mikhailovich Lyapunov, a Russian mathematician, who defended the thesis *The General Problem of Stability of Motion* at Kharkiv University in 1892. Lyapunov was a pioneer in creating the global approach to the analysis of the stability of nonlinear dynamical systems. His work, initially published in Russian and then translated to French, received little attention for many years. The current use of Lyapunov functions has proved that Lyapunov was ahead of his time in developing his theory that is being used in many different areas of sciences. In theory Lyapunov functions are scalar functions that may be used to prove the stability of equilibrium of a given dynamical system. Since the inception of Lyapunov functions, their successful usage has been extended to integral equations, integro-differential equations, and functional differential equations.

7.1 Lyapunov method

The existence of Lyapunov functions is a necessary and sufficient condition for stability in differential equations. There are no concrete procedures on how to find Lyapunov functions, but in some cases, the construction of Lyapunov functions is known. In the particular case of homogeneous autonomous systems with constant coefficients the Lyapunov function can be found as a quadratic form. As we will see later, Lyapunov functions allow us to study the stability of nonlinear dynamical systems when the equilibrium solution of an associated linear differential equation is a center.

Let D be an open set in $\mathbb{R}^n$ containing 0, and let t_0 be any initial time. Define

$$V : [t_0, \infty) \times D \to [0, \infty),$$

where V is any differentiable *scalar* function. If $\psi : [t_0, \infty) \times D \to D$ is any differentiable function, then $V(t) := V(t, \psi(t))$ is a scalar function of it, and using the chain rule, we can compute its derivative

$$V'(t) = \frac{\partial V}{\partial x_1}\psi_1'(t) + \ldots + \frac{\partial V}{\partial x_n}\psi_n'(t) + \frac{\partial V}{\partial t}.$$

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00013-9

Copyright © 2023 Elsevier Inc. All rights reserved.

Copyright Elsevier 2022

Let $f : [t_0, \infty) \times D \to \mathbb{R}^n$ with $f(t, 0) = 0$. Assume the existence of the unknown solution $x : [t_0, \infty) \to D$ for all $(t^*, x_0) \in [t_0, \infty) \times D$ and consider the system

$$x' = f(t, x), \tag{7.1.1}$$

where

$$f(t, x) = \begin{pmatrix} f_1(t, x) \\ f_2(t, x) \\ \vdots \\ f_n(t, x) \end{pmatrix}.$$

Then it follows from the above argument that

$$\begin{aligned} V'(t, x(t)) = {} & \frac{\partial V(t, x(t))}{\partial x_1} f_1(t, x(t)) + \dots \\ & + \frac{\partial V(t, x(t))}{\partial x_n} f_n(t, x(t)) + \frac{\partial V}{\partial t}. \end{aligned} \tag{7.1.2}$$

Thus expression (7.1.2) defines the derivative of the function $V(t, x)$ along the unknown solutions of (7.1.1). Note that if $\nabla V = grad\ V = (\frac{\partial V}{\partial x_1}, \dots, \frac{\partial V}{\partial x_n})$, then expression (7.1.2) takes the form

$$V'(t, x(t)) = grad\ V \cdot f(t, x) + \frac{\partial V}{\partial t},$$

where "·" represents the dot product.

Suppose we are able to find V such that for any $(t, x) \in [t_0, \infty) \times D$, we have

$$\frac{\partial V(t, x(t))}{\partial x_1} f_1(t, x(t)) + \dots + \frac{\partial V(t, x(t))}{\partial x_n} f_n(t, x(t)) + \frac{\partial V}{\partial t} \le 0.$$

Then along the solutions of (7.1.1), we have $V'(t, \psi(t)) \le 0$. Since V is nonincreasing along the solutions and V is increasing in $|x|$, with some work, we are able to get the boundedness of solutions and stability of equilibrium solutions.

The discussion that we gave above regarding the derivative of the function V is not rigor, and more precise definitions and conditions must be imposed. We start with the following definition.

Definition 7.1.1. Let $D \subset \mathbb{R}^n$ be an open set containing the origin, and let $V(t, x) : \mathbb{R}^+ \times D \to R$ be a given function. Then we define $W = \mathbb{R}^+ \times D$ and

$$V'_{(7.1.1)}(t, x(t)) = \limsup_{h \to 0^+} \frac{V(t + h, x + hf(t, x)) - V(t, x)}{h}, \ (t, x) \in W,$$

where f is the right-hand side function of (7.1.1).

Copyright Elsevier 2022

Let $x(t)$ be a solution of (7.1.1) and define

$$V'(t,x(t)) = \limsup_{h\to 0^+} \frac{V(t+h, x(t+h)) - V(t,x(t))}{h}.$$

Definition 7.1.2. Suppose $V(t,x) : \mathbb{R}^+ \times D \to \mathbb{R}^+$ is Lipschitz in x (uniformly in $t \in \mathbb{R}^+$), that is, there exists $L > 0$ such that for all $t \in \mathbb{R}^+$,

$$|V(t,x_1) - V(t,x_2)| \le L\|x_1 - x_2\|, \quad x_1, x_2 \in D.$$

We further assume that $V(t,x)$ is continuous in t and Lipschitz in x (uniformly in t) with Lipschitz constant $L > 0$. We have the following lemma.

Lemma 7.1. *Let $x(t)$ be a solution of* (7.1.1). *Then*

$$V'(t,x(t)) = V'_{(7.1.1)}(t,x(t)). \tag{7.1.3}$$

Moreover, if $Q : W \to [0,\infty)$ is continuous such that

$$V'(t,x(t)) \le -Q(t,x(t)), \tag{7.1.4}$$

then

$$V(t_2,x(t_2)) - V(t_1,x(t_1)) \le -\int_{t_1}^{t_2} Q(t,x(t))dt,\ 0 \le t_1 \le t_2. \tag{7.1.5}$$

Proof. First, we note that since V is a Lipschitz function, we have

$$-L||x_1 - x_2|| \le V(s,x_1) - V(s,x_2) \le L||x_1 - x_2||,\ s \ge 0,\ \ x_1,x_2 \in D.$$

Let $x(t)$ be a solution of (7.1.1). Then

$$\begin{aligned}
&V(t+h, x(t+h)) - V(t,x(t)) \\
&= V(t+h, x(t+h)) - V(t+h, x+hf(t,x)) \\
&+ V(t+h, x+hf(t,x)) - V(t,x(t)).
\end{aligned}$$

Divide the above expression by h, take $\limsup_{h\to 0^+}$, and then apply the Lipschitz condition to get

$$\begin{aligned}
&\limsup_{h\to 0^+} \frac{V(t+h, x(t+h)) - V(t,x(t))}{h} \\
&\le \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x(t))}{h} \\
&+ L \lim_{h\to 0^+} \frac{\|x(t+h) - x(t) - hf(t,x(t))\|}{h}
\end{aligned}$$

Copyright Elsevier 2022

$$= \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x(t))}{h}$$
$$+ L\|x' - f(t,x)\|,$$

which gives

$$V'(t,x(t)) \le \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x)}{h} = V'_{(7.1.1)}(t,x(t)). \quad (7.1.6)$$

In a similar way, but reversing the use of Lipschitz inequality, we get

$$\limsup_{h\to 0^+} \frac{V(t+h, x(t+h)) - V(t,x(t))}{h}$$
$$\ge \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x(t))}{h}$$
$$- L \lim_{h\to 0^+} \frac{\|x(t+h) - x(t) - hf(t,x(t))\|}{h}$$
$$= \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x(t))}{h}$$
$$- L\|x' - f(t,x)\|,$$

which gives

$$V'(t,x(t)) \ge \limsup_{h\to 0^+} \frac{V(t+h, x+hf(t,x)) - V(t,x)}{h} = V'_{(7.1.1)}(t,x(t)). \quad (7.1.7)$$

This shows that

$$V'(t,x(t)) = V'_{(7.1.1)}(t,x(t)).$$

As for (7.1.5), we integrate both sides of (7.1.4) from t_1 to t_2. This completes the proof. □

Remark 7.1. Lemma 7.1 states that the derivative of V with respect to (7.1.1) is the derivative of V along the solution of (7.1.1) and is given by (7.1.2).

The situation is considerably simplified when V is independent of t. In this case (7.1.2) simplifies to

$$V'(x(t)) = \frac{\partial V(x(t))}{\partial x_1} f_1(t,x(t)) + \cdots + \frac{\partial V(x(t))}{\partial x_n} f_n(t,x(t)). \quad (7.1.8)$$

Recall that if x^* is an equilibrium point of (7.1.1), then the change of variables $x = y + x^*$ translates every nonzero equilibrium solution to the origin.

Copyright Elsevier 2022

Definition 7.1.3. Let D be an open set in $\mathbb{R}^n$ containing 0. A continuous autonomous function $V : D \to [0, \infty)$ is *positive definite* if

$$V(0) = 0 \text{ and } V(x) > 0 \text{ for } x \neq 0.$$

The function V is said to be *negative definite* if $-V$ is positive definite.

Definition 7.1.4. Let D be an open set in $\mathbb{R}^n$ containing 0. Let

$$V : D \to [0, \infty)$$

have continuous first partial derivatives. If V is positive definite and

$$V'(x(t)) = \frac{\partial V(x(t))}{\partial x_1} f_1(t, x(t)) + \cdots + \frac{\partial V(x(t))}{\partial x_n} f_n(t, x(t)) \leq 0$$

for $(t, x) \in [t_0, \infty) \times D$, and $x \neq 0$, then V is called a *Lyapunov function* for system (7.1.1).

If the inequality is strict, that is, $V'(x(t)) < 0$, then V is said to be a *strict Lyapunov function*.

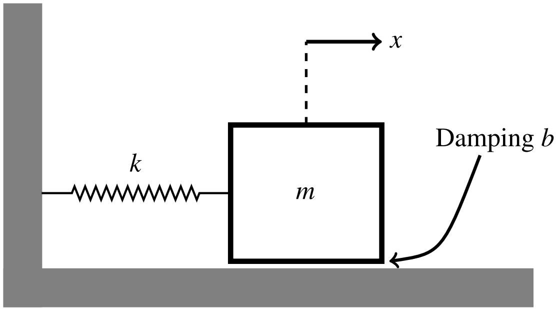

FIGURE 7.1

Damping harmonic motion.

Consider the damped harmonic motion depicted in Fig. 7.1, where m, k are positive constants and $a \geq 0$. If x is the displacement of the mass from its equilibrium position, then applying Newton's second law to all forces acting on the system, we arrive at the second-order differential equation

$$mx'' + bx' + kx = 0.$$

We introduce the transformation $x_1 = x$ and $x_2 = x'$ and arrive at the system

$$x_1' = x_2, \quad x_2' = -\frac{k}{m} x_1 - \frac{b}{m} x_2. \tag{7.1.9}$$

Copyright Elsevier 2022

Clearly, if $b = 0$, then linearization gives no information regarding the stability of the origin. Next, we try to construct a Lyapunov function that overcomes such difficulties. Since we are dealing with a physical system, we expect that the system energy will decrease over time to zero. Thus a logical choice for a Lyapunov function would be the sum of *kinetic energy* and *spring potential energy*, that is,

$$V(x) = \frac{1}{2}m(x')^2 + \frac{1}{2}kx^2.$$

Clearly, V is positive definite, and

$$\begin{aligned} V' &= mx'x'' + kxx' \\ &= x'\big(mx'' + kx\big) \\ &= x'(-bx') \\ &= -b(x')^2. \end{aligned}$$

Later on, we show that this is enough to demonstrate that the origin is stable. We make the following definitions regarding stability.

Definition 7.1.5.

$$x' = f(t, x), \tag{7.1.10}$$

where $x(t) \in \mathbb{R}^n$. Assume that f is continuous and locally Lipschitz with respect to x. Let $t \to x(t, t_0, x_0)$ denote the maximal defined solution of (7.1.10) satisfying the initial condition $x(t_0) = x_0$. Let

$$\phi : [t_0, \infty) \to \mathbb{R}^n$$

be a solution of the differential equation (7.1.10).

(a) We say that the solution ϕ is *stable* (S) on $[t_0, \infty)$ if for each $\varepsilon > 0$, there is $\delta = \delta(t_0, \varepsilon) > 0$ such that whenever $|\phi(t_0) - x_0| < \delta$, the solution $x(t, t_0, x_0)$ is defined for all $t \in [t_0, \infty)$, and

$$|\phi(t) - x(t, t_0, x_0)| < \varepsilon \ \text{ for all } \ t \geq t_0.$$

(b) We say that the solution ϕ is *uniformly stable* (US) on $[t_0, \infty)$ if it is stable and given $\varepsilon > 0$ as before, δ in (a) is independent of t_0 and such that whenever $|\phi(t_0) - x_0| < \delta$, the solution $x(t, t_0, x_0)$ is defined for all $t \in [t_0, \infty)$, and

$$|\phi(t) - x(t, t_0, x_0)| < \varepsilon \ \text{ for all } \ t \geq t_0.$$

(c) We say that the solution ϕ is *asymptotically stable* (AS) on $[t_0, \infty)$ if it is stable and given $\varepsilon > 0$ as before, there is $\delta_1 < \delta$ such that whenever $|\phi(t_0) - x_0| < \delta_1$, we have $\lim\limits_{t\to\infty} |\phi(t) - x(t, t_0, x_0)| = 0$.

Copyright Elsevier 2022

- **(d)** If ϕ is not stable, then we say that it is *unstable*, that is, there is some $\varepsilon > 0$ such that for every $\delta > 0$, there is some point x_0 with $|\phi(t_0) - x_0| < \delta$ such that $|\phi(t_1) - x(t_1, t_0, x_0)| \geq \varepsilon$ for some $t_1 \in [t_0, \infty)$.
- **(e)** We say that the solution ϕ is *uniformly asymptotically stable* (UAS) on $[t_0, \infty)$ if it is US and there exists $\gamma > 0$ such that for each $\mu > 0$, there exists $T = T(\mu) > 0$ such that $|\phi(t_0) - x_0| < \gamma$, $t \geq t_0 + T$, implies $|x(t, t_0, x_0) - \phi(t)| < \mu$.

Since any equilibrium solution can be translated to the origin, we have the equivalent definitions regarding the zero solution $x = 0$.

Let $f : [t_0, \infty) \times D \to \mathbb{R}^n$ with $D \subset \mathbb{R}^n$ containing the origin. Assume the existence of the unknown solution $x : [t_0, \infty) \to D$ on each $(t^*, x_0) \in [t_0, \infty) \times D$ and consider system (7.1.1) with the initial condition $x(t_0) = x_0$ and $f(t, 0) = 0$.

Definition 7.1.6. The zero solution ($x = 0$) of (7.1.1):

- **(a)** is *stable* (S) if for all $\varepsilon > 0$ and $t_0 \geq 0$, there is $\delta = \delta(t_0, \varepsilon) > 0$ such that $|x(t_0)| < \delta$ implies $|x(t, t_0, x_0)| < \varepsilon$,
- **(b)** is *uniformly stable* (US) if δ in (a) is independent of t_0,
- **(c)** is *unstable* if it is not stable,
- **(d)** is *asymptotically stable* (AS) if it is stable and $\lim_{t \to \infty} |x(t, t_0, x_0)| = 0$, and
- **(e)** is *uniformly asymptotically stable* (UAS) if it is US and there exists $\gamma > 0$ such that for each $\mu > 0$, there exists $T = T(\mu) > 0$ such that $|x(t_0)| < \gamma$, $t \geq t_0 + T$, implies $|x(t, t_0, x_0)| < \mu$.

Thus $x = 0$ is stable if solutions starting near $x = 0$ do not wander too far from $x = 0$ in future time. Now $x = 0$ is asymptotically stable if it is stable, and solutions near x_0 approach 0 as $t \to \infty$. The next result is useful in constructing positive definite or negative definite functions and is stated in the following theorem.

Theorem 7.1.1. *For constants a, b, and c, the function*

$$V(x, y) = ax^2 + bxy + cy^2$$

is positive definite if and only if

$$a > 0 \text{ and } 4ac - b^2 > 0$$

and is negative definite if and only if

$$a < 0 \text{ and } 4ac - b^2 > 0.$$

Example 7.1. Consider the planar system

$$x' = -x - xy^2,$$
$$y' = -y - yx^2.$$

Set

$$V(x, y) = ax^2 + bxy + cy^2.$$

Copyright Elsevier 2022

Computing the derivative of V along the solutions of the system, we obtain

$$V'(x,y) = -2[2a(x^2 + x^2y^2) + b(2xy + xy^3 + yx^3) + 2c(y^2 + x^2y^2)].$$

If we choose $b = 0$, $a > 0$, and $c > 0$, then V' is negative definite, and V is positive definite by Theorem 7.1.1.

7.1.1 Stability of autonomous systems

Let D be an open subset of $\mathbb{R}^n$ containing 0, and let $f : D \to \mathbb{R}^n$ with $f(0) = 0$. Assume the existence of the unknown solution $x : [t_0, \infty) \to D$ for each $(t^*, x_0) \in [t_0, \infty) \times D$ and consider the system

$$x' = f(x),\ x(0) = x_0,\ t \geq 0, \tag{7.1.11}$$

where

$$f(x) = \begin{pmatrix} f_1(x) \\ f_2(x) \\ \vdots \\ f_n(x) \end{pmatrix}.$$

Note that Definitions 7.1.3, 7.1.4, and 7.1.6 carry over to the autonomous system (7.1.11). We make the following definitions regarding an open ball so that we may state the stability notion in terms of such balls.

Definition 7.1.7. Let $x^* \in \mathbb{R}^n$ and $r > 0$. Then $B_r(x^*)$ denotes the open ball centered at x^* with radius r, that is,

$$B_r(x^*) = \{x \in \mathbb{R}^n : ||x - x^*|| < r\}.$$

Definition 7.1.8. The equilibrium point x^* of (7.1.11):

- **(a)** is *stable* (S) if for each ball $B_\varepsilon(x^*)$, there is a ball $B_\delta(x^*)$ ($\delta \leq \varepsilon$) such that if $x \in B_\delta(x^*)$, then $x(t, x_0)$ remains in the ball $B_\varepsilon(x^*)$ for $t \geq 0$,
- **(b)** is *asymptotically stable* (AS) if it is *stable* and there is a ball $B_c(x^*)$ such that for each $x \in B_c(x^*)$, $x(t, x_0) \to 0$ as $t \to \infty$.

We warm up with the following example.

Example 7.2. The origin $(0, 0)$ is the only equilibrium solution and is a node for the system

$$x' = -x,$$
$$y' = -y.$$

We apply Definition 7.1.8. The solution is easily computed and is given by

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} c_1 e^{-t} \\ c_2 e^{-t} \end{pmatrix}$$

Copyright Elsevier 2022

for $x(0) = c_1$ and $y(0) = c_2$. For all $\varepsilon > 0$, let $\delta = \varepsilon > 0$. Then for all $c \in B_\delta(0) = \{(x, y) \in \mathbb{R}^2 : \sqrt{x^2 + y^2} < \delta\}$ and $t > 0$, we have

$$||(x, y)|| = \sqrt{x^2(t) + y^2(t)} = \sqrt{(c_1^2 + c_2^2)e^{-2t}} \leq \delta = \varepsilon.$$

It follows that

$$(x(t, 0, c_1), y(t, 0, c_2)) \in B_\delta(0),$$

and hence $(0, 0)$ is stable. Moreover,

$$(x(t, 0, c_1), y(t, 0, c_2)) \to (0, 0) \text{ as } t \to \infty$$

shows that $(0, 0)$ is AS.

Theorem 7.1.2. *Let $V(x)$ be a Lyapunov function in D, that is, $V : D \to [0, \infty)$,*

$$V(0) = 0, \quad V(x) > 0, \text{ and } V' \leq 0 \text{ for } x \neq 0.$$

Then the zero solution of (7.1.11) *is stable.*

Proof. Pick $\varepsilon > 0$ such that the ball $B_\varepsilon(0)$ is in D. Let S_ε be the boundary of $B_\varepsilon(0)$. Due to the continuity of V at the origin and $V(0) = 0$, there must be a point on S_ε where V attains its minimum, which we denote by $m = \min_{x \in S_\varepsilon} V(x) > 0$. Let $B_\delta(0)$ be another ball in D. Since $V(0) = 0$ and V is continuous we can choose $\delta > 0$ such that $V(x) < m$ for all $x \in B_\delta(0)$. Our goal is to show that if $x_0 \in B_\delta(0)$, then $x(t, 0, x_0) \in B_\varepsilon(0)$ for all $t > 0$. Since $V' \leq 0$, then $V(x_0) < m$ implies that $V(x(t, 0, x_0)) < m$ for all $t > 0$ because the nonpositivity of the derivatives implies that V does not increase along the orbits with the initial condition x_0. This in turn implies that $x(t, 0, x_0)$ cannot cross S_ε since $V(x) \geq m$ for all $\in S_\varepsilon$. This implies that the origin is stable. This completes the proof. ☐

Example 7.3. Consider the planar system

$$\begin{aligned} x' &= -y + xy, \\ y' &= x - x^2. \end{aligned}$$

Clearly, $(0, 0)$ is an equilibrium point of the system. The linearization theorem, Theorem 6.2.1, is inconclusive since $(0, 0)$ is a center for the linear part

$$\begin{aligned} x' &= -y, \\ y' &= x. \end{aligned}$$

Moreover, using the method of polar coordinates gives no information about the stability of the origin. Let us try to construct a Lyapunov function. Let a and b be positive constants and set

$$V(x, y) = ax^2 + by^2,$$

Copyright Elsevier 2022

where a and b are to be determined. It is clear that $V(0,0) = 0$ and $V(x,y) > 0$ for $(x,y) \neq (0,0)$.

Computing the derivative of V along the solutions of the system using (7.1.8), we obtain

$$\begin{aligned} V'(x,y) &= axx' + byy' \\ &= ax(-y + xy) + by(x - x^2) \\ &= 0 \end{aligned}$$

by setting $a = b > 0$. The simplest choice would be $a = \frac{1}{2} = b$. In this case,

$$V(x,y) = \frac{1}{2}(x^2 + y^2).$$

Thus by Theorem 7.1.2 the origin is stable.

Here is another example.

Example 7.4. Consider the three-dimensional system

$$\begin{aligned} x' &= -2y + yz, \\ y' &= x - xz, \\ z' &= xy. \end{aligned}$$

Clearly, $(0,0,0)$ is an equilibrium solution of the system, and

$$J(0,0,0) = \begin{pmatrix} 0 & -2 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Thus $J(0,0,0)$ has the eigenvalues $\lambda_1 = 0$ and $\lambda_2 = \lambda_3 = i\sqrt{2}$. The linearization theorem, Theorem 6.2.1, cannot be applied. Let us try to construct a Lyapunov function. Let a, b, and c be positive constants and set

$$V(x,y) = ax^2 + by^2 + cz^2,$$

where a and b are to be determined. It is clear that $V(0,0) = 0$ and $V(x,y,z) > 0$ for $(x,y,z) \neq (0,0,0)$. Computing the derivative of V along the solutions of the system using (7.1.8), we obtain

$$\begin{aligned} V'(x,y) &= axx' + byy' + czz' \\ &= ax(-2y + yz) + by(x - xz) + cz(xy) \\ &= 2[(a - b + c)xyz + (-2a + c)xy]. \end{aligned}$$

Copyright Elsevier 2022

Hence if $b = 2a$ and $c = a > 0$, then $V'(x, y, z) = 0$ for all $(x, y, z) \in \mathbb{R}^3$, and therefore by Theorem 7.1.2 the origin $(0, 0, 0)$ is stable. Furthermore, choosing $a = c = 1$ and $b = 2$, we see that the trajectories of this system lie on the ellipsoids

$$x^2 + 2y^2 + z^2 = k^2$$

for positive constants k.

Example 7.3 reveals the advantage of the use of Lyapunov functions over linearization since it showed that a center for a linear system is stable for the accompanying nonlinear system.

The next theorem provides criteria for asymptotic stability.

Theorem 7.1.3. *Let $V(x)$ be a strict Lyapunov function in D, that is, $V : D \to [0, \infty)$,*

$$V(0) = 0, \quad V(x) > 0, \text{ and } V' < 0 \text{ for } x \neq 0.$$

Then the zero solution of (7.1.11) *is asymptotically stable.*

Proof. Since the origin is stable and $V' < 0$ along the solutions of (7.1.11), it follows that $V(x)$ decreases to the value c as $t \to \infty$. The proof will be complete if we show that $c = 0$. Assume for contradiction that $c > 0$. Then there exists $\beta < \varepsilon$ (ε from the stability theorem) such that $V(x) < c$ for all $x \in B_\beta(0)$. However, then $x(t)$ cannot enter $B_\beta(0)$. Let

$$m = \min\{-V' : \beta \leq |x| \leq \varepsilon\}.$$

As $-V' > 0$, we have that $V' \leq -m$ for all $t \geq 0$. An integration of $V' \leq -m$ from 0 to t yields

$$V(x(t)) - V(x_0) \leq -mt.$$

Thus $\lim_{t \to \infty} V(x(t)) = -\infty$, which contradicts the assumption that V is positive definite in D and tends to c as $t \to \infty$. Hence c must vanish.

We next claim that $x(t) \to 0$ as $t \to \infty$. If this is not the case, then there are constants $\alpha > 0$ and a sequence $t_k \to \infty$ such that $|x(t)| \geq \alpha$ for all k. Since the closure $\bar{B}_\beta(0)$ is compact and all the points $x(t_k) \in \bar{B}_\beta(0)$, there is a subsequence that converges to a point $z \in B_\beta(0)$. We may assume that $x(t_k) \to z$, and we must have $0 \neq |z| \geq \alpha$. By the continuity of V we have that $V(x(t_k)) \to V(z) > 0$. However, since $t_k \to \infty$, we must have $V(x(t_k)) \to c = 0$, which is a contradiction. Thus the origin is asymptotically stable. This completes the proof. □

Example 7.5. Consider the planar system

$$\begin{aligned} x' &= -x - xy^2, \\ y' &= -y + 3x^2 y. \end{aligned}$$

Copyright Elsevier 2022

Clearly, $(0,0)$ is an equilibrium point of the system. The linearization theorem, Theorem 6.2.1, tells us that $(0,0)$ is AS. We verify the result by constructing a strict Lyapunov function. Let a and b be positive constants and set

$$V(x,y) = ax^2 + by^2,$$

where a and b are to be determined. Clearly, $V(0,0) = 0$ and $V(x,y) > 0$ for $(x,y) \neq (0,0)$. Computing the derivative of V along the solutions of the system using (7.1.8), we obtain

$$\begin{aligned}
V'(x,y) &= axx' + yy' \\
&= ax(-x - xy^2) + by(-y + 3x^2y) \\
&= -2ax^2 - 2ax^2y^2 - 2by^2 + 6bx^2y^2 \\
&= -(6x^2 + 2y^2) < 0
\end{aligned}$$

unless $x = y = 0$, where we choose $a = 3$, $b = 1$ to eliminate the mixed terms. Thus by Theorem 7.1.3 the origin is asymptotically stable.

Note that the origin $(0,0)$ of the system in Example 7.1 is asymptotically stable by Theorem 7.1.3.

Let $V(x)$ be a strict Lyapunov function in D. Then *domain of attraction* of an equilibrium consists of all points such that a solution starting at them tends to the equilibrium. In engineering applications, it is often important to get an estimate of the size of the domain of attraction. Thus if V is a strict Lyapunov function on a set $D \in \mathbb{R}^n$, then the origin is asymptotically stable, and the *domain of attraction* is

$$\bar{N} = \{x \in D : V(x) \leq C\}$$

for some positive constant C.

Example 7.6. Consider the planar system

$$\begin{aligned}
x' &= -x - y, \\
y' &= 2x - y + y^3.
\end{aligned}$$

Clearly, $(0,0)$ is an equilibrium point of the system. Set

$$V(x,y) = x^2 + \frac{y^2}{2}.$$

Clearly, $V(0,0) = 0$, and $V(x,y) > 0$ for $(x,y) \neq (0,0)$. Computing the derivative of V along the solutions of the system, we obtain

$$\begin{aligned}
V'(x,y) &= 2xx' + yy' \\
&= 2x(-x - y) + y(2x - y + y^3) \\
&= -2x^2 - y^2 + y^4.
\end{aligned}$$

Copyright Elsevier 2022

To keep $V'(x,y) < 0$, we must restrict y so that $-y^2 + y^4 = y^2(-1+y^2) < 0$, that is, $-1 < y < 1$. On the other hand, to keep the ellipses $V(x,y) = x^2 + \frac{y^2}{2} = C$ inside $D = \{(x,y) : x \in \mathbb{R},\ -1 < y < 1\}$, we must take $0 < C < \frac{1}{2}$. Thus for any value of such C, the origin is asymptotically stable, and the domain of attraction is

$$\bar{N} = \{x \in D : V(x) \le C < \frac{1}{2}\}.$$

The next theorem only asks for the existence of a Lyapunov function to obtain the asymptotic stability but with a catch.

Theorem 7.1.4. *Let $V(x)$ be a Lyapunov function in D. Let*

$$Z = \{x : V'(x) = 0, x \in D\}.$$

Suppose that the only bounded solution of (7.1.11) *that remains inside Z all the time is the equilibrium solution* 0. *Then the origin of* (7.1.11) *is asymptotically stable.*

Proof. Theorem 7.1.4 is a particular case of Theorem 7.4.2, and we ask the reader to either wait or flip the pages. ☐

As an application of Theorem 7.1.4, we provide the following example.

Example 7.7. Consider the planar system

$$\begin{aligned} x' &= -x - 2y, \\ y' &= 3x - 2y. \end{aligned}$$

Clearly, $(0,0)$ is an equilibrium point of the system. Set

$$V(x,y) = \frac{x^2}{2} + y^2.$$

Clearly, $V(0,0) = 0$ and $V(x,y) > 0$ for $(x,y) \neq (0,0)$. Computing the derivative of V along the solutions of the system, we obtain

$$\begin{aligned} V'(x,y) &= xx' + 2yy' \\ &= x(-x-2y) + 2y(3x-2y) \\ &= -(x-2y)^2. \end{aligned}$$

It is clear that $V'(x,y) = 0$ if $x = 2y$. Thus $V(x,y)$ is a Lyapunov function (not strict) on the set

$$Z = \{(x,y) \in \mathbb{R}^2 : x = 2y\}.$$

Let (x,y) be a bounded solution (trajectory) in Z, that is, there exists a positive constant K such that $|x|,\ |y| \le K$. Substitute $x = 2y$ into the original system to get $x' = -2x$ and $y' = 4y$. By straightforward calculations we obtain the solutions

$$x(t) = x(0)e^{-2t} \text{ and } y(t) = y(0)e^{4t},$$

Copyright Elsevier 2022

respectively, for $t \in \mathbb{R}$. These functions cannot satisfy $|x|, |y| \leq K$, unless $x(0) = y(0) = 0$. To have you more convinced, the solutions must also satisfy $x = 2y$, or

$$x(0)e^{-2t} = 2y(0)e^{4t},$$

which can only hold if $x(0) = y(0) = 0$. Thus the only bounded solution in Z is the origin, and hence by Theorem 7.1.4 the origin is asymptotically stable.

The next theorem provides criteria for instability of the zero solution of (7.1.11).

Theorem 7.1.5. *Let D be an open set in $\mathbb{R}^n$ containing* 0*. Let $V : D \to [0, \infty)$ be continuous real-valued scalar differentiable function that is positive definite on D. If $V'(x) > 0$ for $x \neq 0$, then the origin of* (7.1.11) *is unstable.*

Proof. Assume that the zero solution is stable. Then, for $\varepsilon = 1$ and $t_0 = 0$, there exists $\delta > 0$ such that $|x_0| < \delta$ implies that $|x(t, 0, x_0)| \leq 1$. Hence for $x(t) = x(t, 0, x_0)$, $V(x(t))$ is bounded for $t \geq 0$ when $|x_0| \leq \delta$. Fix x_0 with $|x_0| = \frac{\delta}{2}$ such that $V(x_0) > 0$. Since $V' > 0$, it follows that V is increasing along the solutions. Therefore we have $V(x(t)) \geq V(x_0) > 0$, $t \geq 0$. Since V is continuous and $V(0) = 0$, there exists $p \in (0, 1)$ such that $p \leq |x(t)| \leq 1$, $t \geq 0$. Since $V' > 0$ along the solutions of (7.1.11) and positive on the closed and bounded set $p \leq |x(t)| \leq 1$, we have $l = \min\limits_{p \leq |x| \leq 1} V'(x) > 0$. Thus

$$V(x(t)) - V(x_0) = \int_0^t \frac{d}{ds} V(x(s))ds \geq \int_0^t l ds = l(t - t_0) \to \infty, \ t \to \infty.$$

This contradicts the fact that $V(x(t))$ is bounded for $t \geq 0$ when $|x_0| < \delta$. It follows that the zero solution $x(t) = 0$ is unstable. ☐

Example 7.8. Consider the planar system

$$x' = 2xy + x^3,$$
$$y' = -x^2 + y^5.$$

Clearly, $(0, 0)$ is an equilibrium point of the system. Linearization will not work here since there are no linear terms at $(0, 0)$. Set

$$V(x, y) = x^2 + 2y^2.$$

Clearly, $V(0, 0) = 0$ and $V(x, y) > 0$ for $(x, y) \neq (0, 0)$. Computing the derivative of V along the solutions of the system, we obtain

$$\begin{aligned} V'(x, y) &= 2xx' + 4yy' \\ &= 2x(2xy + x^3) + 4y(-x^2 + y^5) \\ &= 2x^4 + 4y^6 > 0, \ \ (x, y) \neq (0, 0). \end{aligned}$$

It follows from Theorem 7.1.5 that the origin is unstable.

Copyright Elsevier 2022

Example 7.9. We examine the stability and asymptotic stability for different values of a for the planner system

$$\begin{aligned} x' &= ax(x^2+y^2) - xy^2, \\ y' &= ay(x^2+y^2) + x^2y. \end{aligned}$$

Clearly, $(0,0)$ is an equilibrium point of the system. Linearization will not work here since there are no linear terms in the neighborhood of $(0,0)$. Set

$$V(x,y) = x^2+y^2.$$

Clearly, $V(0,0)=0$ and $V(x,y)>0$ for $(x,y)\neq(0,0)$. Set $V(t) := V(x(t),y(t))$. Then along the solutions of the system we have that

$$\begin{aligned} V'(t) &= 2xx' + 2yy' \\ &= 2x[ax(x^2+y^2) - xy^2] + 2y[ay(x^2+y^2) + x^2y] \\ &= 2a(x^2+y^2)^2. \end{aligned} \tag{7.1.12}$$

It is clear from relation (7.1.12) that the origin is stable if $a=0$, asymptotically stable if $a<0$, and unstable if $a>0$. In the following, we will use expression (7.1.12) and try to understand the behavior of the Lyapunov function along the solutions.

We observe that (7.1.12) is equivalent to

$$V'(t) = 2aV^2(t),$$

which is a separable first-order differential equation in $V(t)$. Thus separating the variables and then integrating from 0 to t gives

$$V(t) = \frac{V(0)}{1-2aV(0)t}, \ t \geq 0. \tag{7.1.13}$$

Case 1. If $a=0$, then from (7.1.13) we have that $V(t)=V(0)=x(0)^2+y(0)^2>0$. In this case, we have a periodic solution surrounding the origin

$$x^2+y^2=k^2$$

for nonzero constant k. Hence the origin is stable.

Case 2. If $a<0$, then from (7.1.13) we have that $V(t)\to 0$ as $t\to\infty$, that is, $x^2+y^2\to 0$ as $t\to\infty$, which means that the solutions spiral toward the origin, and we conclude that the origin is asymptotically stable.

Case 3. If $a>0$, then by (7.1.13) $V(t)$ is not defined for all $t\geq 0$. In fact, $V(t)\to\infty$ as $t\to\frac{1}{2aV(0)}$ from the left. We conclude that the origin is unstable.

The next theorem provides criteria of the instability of the zero solution, which is different from that given in Theorem 7.1.5.

Copyright Elsevier 2022

Theorem 7.1.6. *Let x^* be an equilibrium solution of (7.1.11). Let U be a neighborhood of x^*. Let $V : U \to \mathbb{R}$ be a continuously differentiable function on U, except perhaps at x^*. If $V(x^*) = 0$, but there are points arbitrarily close to x^* where V is strictly positive and $V' > 0$ on $U \setminus \{x^*\}$, then x^* is unstable for (7.1.11).*

Proof. Without loss of generality, we take $x^* = 0$. Let $B_\beta(0) \subseteq U$, $\beta > 0$. We may choose a point $x_0 \in B_\beta(0)$ close to 0 such that $V(x_0) > 0$. Let (a, b) be the interval of existence of the solution $x(t) = x(t, x_0)$. The proof will be completed if we can show that $x(t)$ is outside the ball $\bar{B}_\beta(0)$. Assume the contrary, that is, solutions stay in $B_\beta(0)$ for all $t \geq 0$. Since $\bar{B}_\beta(0)$ is compact, V achieves its maximum, say $V_0 \in \bar{B}_\beta(0)$. Thus

$$V(x(t)) \leq V_0, \quad t \geq 0. \tag{7.1.14}$$

Since $V' > 0$ and V is increasing along the solutions and $V' \geq V(x_0) > 0$, we can find $\rho > 0$ such that $V(x) < V(x_0)$ for $x \in B_\rho(0)$. Then $x(t)$ is trapped in the compact annulus $\rho \leq |x| \leq \beta$. Let

$$m = \min\{V' : \rho \leq |x| \leq \beta\}.$$

An integration of $V' \geq m$ from 0 to t yields

$$V(x(t, x_0)) \geq V(x_0) + mt,$$

which contradicts (7.1.14) since the right side goes to infinity as t goes to infinity. Thus the solution $x(t)$ must escape $B_\beta(0)$, and the origin is unstable. This completes the proof. □

Lyapunov functions can also be used to determine limit cycles, as the next example demonstrates.

Example 7.10. In Example 6.15 we considered the planar autonomous system

$$x' = -y - x(x^2 + y^2 - \mu), \quad y' = x - y(x^2 + y^2 - \mu)$$

with $\mu > 0$ and used polar coordinates to show the existence of a stable limit cycle. In this example, we use a Lyapunov function to arrive at the same result. Let

$$V(x, y) = x^2 + y^2.$$

Then along the solutions of the system we have the expression

$$\begin{aligned} V'(t) &= 2xx' + 2yy' \\ &= 2x[-y - x(x^2 + y^2 - \mu)] + 2y[x - y(x^2 + y^2 - \mu)] \\ &= -2(x^2 + y^2 - \mu)(x^2 + y^2) \\ &= 2\big(\mu - V(x, y)\big)V(x, y). \end{aligned}$$

Copyright Elsevier 2022

Now since $V > 0$, the sign of V' depends on the term $\mu - V(x, y)$. We have $V' = 0$ if $V = \mu$ or $x^2 + y^2 = \mu$, which is a circle centered at the origin with radius μ. If $0 < V < \mu$, then $V' > 0$. In this case the trajectories start inside the circle with radius μ and move upward toward it but do not cross it due to uniqueness. If $V > \mu$, then $V' < 0$. In this case the trajectories start outside the circle with radius μ and move toward it but do not cross it due to uniqueness. We conclude that $x^2 + y^2 = \mu$ is a stable limit cycle.

The next example shows the importance of Theorem 7.1.6 and illustrates its usage as Theorem 7.1.5 is not applicable.

Example 7.11. Considered the planar autonomous system

$$x' = 3x + y^2, \quad y' = -2y + x^3.$$

Clearly, the origin is the only equilibrium point of the system. We easily conclude that $(0, 0)$ is unstable using the linearization method. Let us see how we can implement Theorem 7.1.6. We consider the Lyapunov function

$$V(x, y) = \frac{x^2}{2} - \frac{y^2}{2}.$$

There are points in the neighborhood of the origin where V is positive, for example, the points on the x-axis. Since we are only interested what happens in the neighborhood of $(0, 0)$, we limit ourselves to $|x| < 1$ and $|y| < 1$. To better understand the derivative of V, we will utilize the inequality

$$0 < (a - b)^2 = a^2 - 2ab + b^2$$

for all real numbers a and b, from which it follows that

$$ab \le \frac{a^2}{2} + \frac{b^2}{2}.$$

It readily follows that along the solutions of the system,

$$V' = (3x^2 + 2y^2) + (xy^2 - x^3 y). \tag{7.1.15}$$

Next, we compare the term $(3x^2 + 2y^2)$ with $(xy^2 - x^3 y)$:

$$\begin{aligned} \left|xy^2 - x^3 y\right| &\le |xy||y - x^2| \\ &\le \frac{1}{2}(x^2 + y^2)(x^2 + |y|) \\ &\le \frac{1}{2}(x^2 + y^2)(|x| + |y|) \\ &\le \frac{1}{2}(|x| + |y|)(|x| + |y|) \end{aligned}$$

Copyright Elsevier 2022

$$
\begin{aligned}
&= \frac{1}{2}(|x|^2 + |y|^2) + |x||y| \\
&\le \frac{1}{2}(|x|^2 + |y|^2) + \frac{1}{2}(|x|^2 + |y|^2) \\
&= x^2 + y^2 \\
&\le 3x^2 + 2y^2.
\end{aligned}
$$

Thus a substitution into (7.1.15) gives

$$V'(t) \ge \left|xy^2 - x^3y\right| + (xy^2 - x^3y) > 0$$

for $(x, y) \neq (0, 0)$. We conclude that $V' > 0$ on the set $|x|, |y| < 1$ minus the origin, and by Theorem 7.1.6 the origin is unstable. Note that the set U of Theorem 7.1.6 is defined by

$$U = \{x, y \in \mathbb{R} : |x| < 1,\ |y| < 1\}.$$

Theorem 7.1.6 also has its limitation since there may be some points near the equilibrium solution x^* that approach x^*, which makes it difficult to have $V' > 0$ on a whole neighborhood of x^*. The next generalization theorem is due to Četaev.

Theorem 7.1.7. *(Četaev) Let x^* be an equilibrium solution of (7.1.11) contained in the closure of an open set U, and let E be a neighborhood of x^*. Let $V : E \to \mathbb{R}$ be a continuously differentiable function on E such that*

(1) V and V' are both positive on $(U \cap E) \setminus \{x^*\}$.
(2) $V(x) = 0$ on the part of the boundary of U that is in E.

Then the equilibrium solution x^* is unstable.

Proof. Exercise. □

Next, we briefly discuss a special class of Lyapunov functions that includes the absolute value of the unknown solution. Let $x : \mathbb{R} \to \mathbb{R}$ be continuous. Observing that

$$|x| = \sqrt{x^2} = (x^2)^{\frac{1}{2}}$$

and using the chain rule, we arrive at

$$
\begin{aligned}
\frac{d}{dt}|x(t)| &= \frac{1}{2}(x^2(t))^{-\frac{1}{2}}(2x(t)x'(t)) \\
&= \frac{x(t)}{(x^2(t))^{\frac{1}{2}}}x'(t) \\
&= \frac{x(t)}{|x(t)|}x'(t).
\end{aligned}
$$

We have the following lemma.

Copyright Elsevier 2022

Lemma 7.2. *Let $x : \mathbb{R} \to \mathbb{R}$ be differentiable. Then*

$$\frac{d}{dt}|x(t)| = \frac{x(t)}{|x(t)|}x'(t).$$

Example 7.12. Consider the scalar nonlinear Volterra integro-dynamic equation

$$x'(t) = ax(t) + b\frac{x(t)}{1 + \int_0^t x^2(s)ds}, \quad t \in [0, \infty). \tag{7.1.16}$$

Suppose there exists a constant β such that

$$a + |b| = \beta.$$

Consider the function

$$V(t, x) = |x(t)|.$$

Then by Lemma 7.2, we have

$$\begin{aligned} V'(t,x) &= \frac{d}{dt}|x(t)| = \frac{x(t)}{|x(t)|}x'(t) \\ &= \frac{x(t)}{|x(t)|}\Big(ax(t) + b\frac{x(t)}{1 + \int_0^t x^2(s)ds}\Big) \\ &= ax^2\frac{1}{|x(t)|} + \frac{x}{|x|}b\frac{x(t)}{1 + \int_0^t x^2(s)ds} \\ &\le a|x| + |b||x|\frac{1}{1 + \int_0^t x^2(s)ds} \\ &\le a|x| + |b||x| \\ &= (a + |b|)|x|. \end{aligned}$$

Then it follows from Theorems 7.1.2–7.1.5 that the zero solution of (7.1.16) is stable if $\beta = 0$, asymptotically stable if $\beta < 0$, and unstable if $\beta > 0$.

7.1.2 Time-varying systems; non-autonomous

Now we turn our attention to systems that explicitly include the variable time t. Such systems are referred to as non-autonomous systems. Thus we consider the non-autonomous system

$$x' = f(t, x), \tag{7.1.17}$$

where $f \in C\big([0, \infty) \times D, \mathbb{R}^n\big)$, where $D \subset \mathbb{R}^n$ is open with $0 \in D$. We say that a vector $x^* \in \mathbb{R}^n$ is an *equilibrium solution*, or *constant solution*, or *equilibrium point* of (7.1.17) if

$$f(t, x^*) = 0.$$

Copyright Elsevier 2022

This is the perfect place to make clear that the existence of equilibrium points for non-autonomous systems may depend on the initial time. To see this, we consider

$$x' = \begin{pmatrix} \frac{1}{t} & t \\ 1 & t \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ t > 0, \ x(0) = x_0.$$

The system has a unique equilibrium solution $(0, 0)$, provided that the matrix is non-singular, which is the case for $t \neq 1$. Thus, in this case, the system attains an equilibrium solution if and only if the initial time $t_0 > 1$.

Definition 7.1.6 of stability carries over to (7.1.17). In addition, the uniform asymptotic stability for (7.1.17) is equivalent to the asymptotic stability for autonomous system. We begin by considering the initial value time-varying scalar differential equation

$$x' = (6t \ \sin(t) - 2t)x, \ \ x(t_0) = x_0, \ \ t_0 \geq 0.$$

Its unique solution passing through (t_0, x_0) is given by

$$\begin{aligned} x(t) &= x_0 \ \exp\Big(\int_{t_0}^{t} (6s\sin(s) - 2s)ds\Big) \\ &= x_0 \ \exp\Big(6\sin(t) - 6t\cos(t) - t^2 - 6\sin(t_0) + 6t_0 + 6t_0\cos(t_0) + t_0^2\Big). \end{aligned}$$

Set

$$c(t_0) = \exp\Big(6\sin(t) - 6t\cos(t) - t^2 - 6\sin(t_0) + 6t_0 + 6t_0\cos(t_0) + t_0^2\Big).$$

Then

$$|x(t)| \leq |x_0| c(t_0)|, \ \ t \geq t_0.$$

Thus for any $\varepsilon > 0$, choose $\delta(t_0, \varepsilon) = \frac{\varepsilon}{c(t_0)}$ so that

$$|x_0| < \delta \Longrightarrow |x(t)| < \varepsilon,$$

and hence the zero solution is stable but not uniformly stable. Note that $c(t_0)$ increases as t_0 increases, and hence δ shrinks as t_0 increases and t is fixed. To be more specific, suppose $t_0 = 2n\pi$, $n = 0, 1, 2, \ldots$, and $x(t)$ is evaluated π seconds later in each case. Then

$$x(t_0 + \pi) = x(t_0)e^{(4n+1)(6-\pi)},$$

and if $x(t_0) \neq 0$, then we get

$$\frac{x(t_0 + \pi)}{x(t_0)} \to \infty \ \text{ as } \ t \to \infty.$$

Thus there is no δ independent of t_0 that would satisfy the requirement for uniform stability.

Copyright Elsevier 2022

Definition 7.1.9. A strictly increasing continuous function $W : [0, \infty) \to [0, \infty)$ with $W(0) = 0$ is called a wedge. (In this book, wedges are always denoted by W or W_i, where i is a positive integer.)

Definition 7.1.10. Let D be an open set in $\mathbb{R}^n$ containing 0. A continuous autonomous function $V : [0, \infty) \times D \to [0, \infty)$ is *positive definite* if

$$V(t, 0) = 0 \text{ and } V(t, x) > 0 \text{ for all } x \neq 0 \text{ and all } t \in [0, \infty).$$

Thus $V(t, x)$ is positive definite if and only if there is a wedge independent of time t such that $V(t, x) \geq W(|x|)$ for all $x \in D$.

Definition 7.1.11. Let D be an open set in $\mathbb{R}^n$ containing 0. Let

$$V : [0, \infty) \times D \to [0, \infty)$$

have continuous first partial derivatives. If V is positive definite and

$$V'(t, x(t)) = \frac{\partial V(t, x(t))}{\partial x_1} f_1(t, x(t)) + \cdots + \frac{\partial V(t, x(t))}{\partial x_n} f_n(t, x(t)) + \frac{\partial V(t, x(t))}{\partial t} \leq 0$$

for $(t, x) \in [t_0, \infty) \times D$ with $x \neq 0$, then V is called *Lyapunov function* for system (7.1.17).

If the inequality is strict, that is, $V'(t, x(t)) < 0$ then V is said to be a *strict Lyapunov function*.

Definition 7.1.12. Let D be an open set in $\mathbb{R}^n$ containing 0. Let

$$V : [0, \infty) \times D \to [0, \infty).$$

We say $V(t, x)$ is:

(a) *decrescent* in D if there is a wedge W_1 such that

$$V(t, x) \leq W_1(|x|) \text{ for all } x \in D,$$

(b) *radially unbounded* if $V(t, x) \to \infty$ as $|x| \to \infty$, which means that for each $M > 0$, there is $N > 0$ such that $V(t, x) > M$ for all $t \in [0, \infty)$ and all x such that $|x| > N$,

(c) both positive definite and decrescent if

$$W_1(|x|) \leq V(t, x) \leq W_2(|x|).$$

Theorem 7.1.8. *Let $D \subset \mathbb{R}^n$ be an open set containing the origin, and let $V(t, x)$: $[0, \infty) \times D \to [0, \infty)$ be a given continuously differentiable function satisfying*

$$V(t, 0) = 0, \tag{7.1.18}$$

Copyright Elsevier 2022

$$W_1(|x|) \le V(t,x), \tag{7.1.19}$$

and

$$V'(t,x) \le 0 \text{ for all } t \ge 0 \text{ and } x \ne 0. \tag{7.1.20}$$

Then the zero solution of (7.1.17) *is stable.*

Proof. By (7.1.20), we have $V'(t,x) \le 0$, V is continuous, $V(t,0) = 0$, and $W_1(|x|) \le V(t,x)$. Let $\varepsilon > 0$ and $t_0 \ge 0$. We must find δ such that $|x_0| < \delta$ and $t \ge t_0$ imply $|x(t,t_0,x_0)| < \varepsilon$. (Throughout these proofs, we assume that ε is small enough so that $|x(t,t_0,x_0)| < \varepsilon$ implies that $x \in D$.) As V is continuous in t and x and $V(t,0) = 0$, there is $\delta > 0$ such that $|x_0| < \delta$ implies $V(t_0,x_0) < W_1(\varepsilon)$. Thus if $t \ge t_0$, $|x_0| < \delta$, and $x = x(t,t_0,x_0)$, then we have

$$W_1(|x(t)|) \le V(t,x) \le V(t_0,x_0) < W_1(\varepsilon).$$

Applying W_1^{-1} to both sides of the above inequality gives

$$|x(t)| \le \varepsilon.$$

This completes the proof. □

Theorem 7.1.9. *Let $D \subset \mathbb{R}^n$ be an open set containing the origin, and let $V(t,x) : [0,\infty) \times D \to [0,\infty)$ be a continuously differentiable function. Assume that* (7.1.18), (7.1.19), *and* (7.1.20) *hold. If, in addition, V satisfies*

$$V(t,x) \le W_2(|x|), \tag{7.1.21}$$

then the zero solution of (7.1.17) *is uniformly stable.*

Proof. For a given ε, we choose $\delta > 0$ such that $W_2(\delta) < W_1(\varepsilon)$, where $W_1(|x|) \le V(t,x) \le W_2(|x|)$. If $t_0 \ge 0$, then we have

$$\begin{aligned} W_1(|x(t)|) \le V(t,x) &\le V(t_0,x_0) \\ &\le W_2(|x_0|) < W_2(\delta) < W_1(\varepsilon), \end{aligned}$$

or $|x(t)| < \varepsilon$, as required. This completes the proof. □

The next example shows that $V'(t,x) \le 0$ is not enough to drive solutions to zero.

Example 7.13. Let $g : [0,\infty) \to (0,\beta]$ with $g(0) = 1$ and $0 < \beta \le 1$. Consider the non-autonomous first-order differential equation

$$x'(t) = \left[g'(t)/g(t)\right]x(t). \tag{7.1.22}$$

It is clear that $x(t) = g(t)$ is a solution of (7.1.22). Our goal is to construct a function

$$V(t,x) = a(t)x^2(t)$$

Copyright Elsevier 2022

such that $V'(t,x) = -\alpha(t)x^2(t)$, where $a(t), \alpha(t) > 0$ for $t \in \mathbb{R}^+$, and $\int_0^\infty \alpha(s)ds < \infty$. Along the solutions of (7.1.22) we have

$$V'(t,x) = \big[a'(t) + 2a(t)\frac{g'(t)}{g(t)}\big]x^2(t).$$

By substituting $V'(t,x) = -\alpha(t)x^2(t)$ we arrive at

$$a'(t) + 2a(t)\frac{g'(t)}{g(t)} = -\alpha(t).$$

It readily follows that the solution is

$$\begin{aligned} a(t) &= [a(0)g^2(0) - \int_0^t \alpha(s)g^2(s)ds]g^2(t) \\ &\geq [a(0)g^2(0) - \beta^2 \int_0^t \alpha(s)ds]/g^2(t). \end{aligned}$$

Since $0 < g \leq 1$ and $\int_{s=0}^\infty \alpha(s) < \infty$, we may choose $a(0)$ large enough to imply that $a(t) > 1$ on $[0,\infty)$. Thus we have shown that $V \geq 0$ and $V' \leq 0$ do not imply that solutions tend to zero. As a matter of fact, there is no wedge W_2 with $V(t,x) \leq W_2(|x|)$. Notice that V is not decrescent.

Theorem 7.1.10. *Let $D \subset \mathbb{R}^n$ be an open set containing the origin, and let $V(t,x) : [0,\infty) \times D \to [0,\infty)$ be a continuously differentiable function satisfying* (7.1.18) *and* (7.1.19)*. If, in addition,*

$$V'(t,x) \leq -W_3(|x|) \text{ for all } t \geq 0, \tag{7.1.23}$$

then the zero solution of (7.1.17) *is asymptotically stable.*

Proof. By Theorem 7.1.8, the zero solution is stable. Therefore given $\varepsilon > 0$, there are $\delta > 0$ and $\gamma > 0$ such that

$$\gamma \leq |x(t,t_0,x_0)| < \varepsilon, \quad t \geq t_0, \quad |x_0| < \delta.$$

Due to (7.1.23) and $|x(t,t_0,x_0)| \geq \gamma$ for $t \geq t_0$, there exists a constant $d > 0$ such that

$$V'(t,x) \leq -d < 0 \text{ for all } t \geq t_0.$$

An integration of $V' \leq -d$ from t_0 to t yields

$$V(t, x(t,t_0,x_0)) \leq V(t_0,x_0) - d(t - t_0).$$

Thus $\lim_{t\to\infty} V(x(t)) = -\infty$, which contradicts the assumption that V is positive definite. Hence no such γ exists, and since $V(t,x)$ is a positive decreasing function, it

Copyright Elsevier 2022

follows that $\lim_{t\to\infty} V(x(t)) = 0$. Therefore

$$\lim_{t\to\infty} x(t, t_0, x_0) = 0$$

which implies that the zero solution is asymptotically stable. This completes the proof. □

Theorem 7.1.11. *Let* $D \subset \mathbb{R}^n$ *be an open set containing the origin, and let* $V(t,x) : [0,\infty) \times D \to [0,\infty)$ *be a continuously differentiable function satisfying*

$$V(t,0) = 0,$$

$$W_1(|x|) \le V(t,x) \le W_2(|x|),$$

and

$$V'(t,x) \le -W_3(|x|) \text{ for all } t \ge 0.$$

Then the zero solution of (7.1.17) *is uniformly asymptotically stable.*

Proof. By Theorem 7.1.9, the zero solution is uniformly stable. Let $\varepsilon = 1$, and find $\delta > 0$ of uniform stability and call it η. Let $\gamma > 0$ be given. We must find $T > 0$ such that

$$|x_0| < \eta, \quad t_0 \ge 0, \quad \text{and } t \ge t_0 + T$$

imply $|x(t, t_0, x_0)| < \gamma$. Pick $\mu > 0$ with $W_2(\mu) < W_1(\gamma)$, so that there is $t_1 \ge t_0$ with $|x(t_1)| < \mu$. Then we have, for $t \ge t_1$,

$$\begin{aligned} W_1(|x(t)|) &\le V(t,x) \le V(t_1, x_1) \\ &\le W_2(|x_1|) < W_2(\eta) < W_1(\gamma), \end{aligned}$$

or $|x(t_1)| < \gamma$. Since $V'(t,x) \le -W_3(|x|)$, and so as long as $|x(t)| > \mu$, it follows that $V'(t,x) \le -W_3(\mu)$. Thus

$$\begin{aligned} V(t, x(t)) &\le V(t_0, x_0) - \int_{t_0}^{t} W_3(|x(s)|)ds \\ &\le W_2(|x_0|) - W_3(\mu)(t - t_0) \\ &\le W_2(\eta) - W_3(\mu)(t - t_0), \end{aligned}$$

which vanishes at

$$t = t_0 + \frac{W_2(\eta)}{W_3(\mu)} \ge t_0 + T,$$

where $T \ge \frac{W_2(\eta)}{W_3(\mu)}$. Hence, if $T > \frac{W_2(\eta)}{W_3(\mu)}$, then $|x(t)| > \mu$ fails, and we have $|x(t)| < \gamma$ for all $t \ge t_0 + T$. This proves UAS. □

Copyright Elsevier 2022

Example 7.14. Consider the second-order differential equation

$$u'' + e(t)u = 0,$$

where e is continuously differentiable with

$$e'(t) \le 0 \text{ and } \lim_{t\to\infty} e(t) = e_0 > 0.$$

Making the substitution $x = u$, $y = u'$, we arrive at the equivalent system

$$x' = y, \;\; y' = -e(t)x.$$

Let

$$V(t, \mathbf{x}) = e(t)x^2 + y^2,$$

where $\mathbf{x} = \begin{pmatrix} x \\ y \end{pmatrix}$. Then along the solutions we have

$$\begin{aligned} V'(t, \mathbf{x}) &= e'(t)x^2 + 2e(t)xy - 2e(t)xy \\ &= e'(t)x^2 \\ &\le 0. \end{aligned}$$

It is clear that $V(t, 0) = 0$. We will show that the zero solution is uniformly stable using Theorem 7.1.9 if we show that $W_1(|\mathbf{x}|) \le V(t, \mathbf{x}) \le W_2(|\mathbf{x}|)$. Since e is decreasing and its limit at infinity exists and is equal to e_0, we may let

$$c = \min\{e_0, 1\} \text{ and } k = \max\{e(0), 1\}.$$

Then we can define

$$W_1(|\mathbf{x}|) = c(x^2 + y^2) = c|\mathbf{x}|, \text{ and } W_2(|\mathbf{x}|) = k(x^2 + y^2) = k|\mathbf{x}|,$$

so that we have $W_1(|\mathbf{x}|) \le e(t)x^2 + y^2 \le W_2(|\mathbf{x}|)$. This implies that the zero solution is uniformly stable.

Example 7.15. Consider the system

$$x_1' = -x_1 - e^{-2t}x_2, \;\; x_2' = x_1 - x_2.$$

Here $(0, 0)$ is the only equilibrium solution. Let

$$V(x_1, x_2) = x_1^2 + (1 + e^{-2t})x_2^2.$$

Then along the solutions we have by Definition 7.1.11 that

$$V'(t, x_1, x_2) = -2\big[x_1^2 - x_1x_2 + x_2^2(1 + 2e^{-2t})\big].$$

Copyright Elsevier 2022

Using $x_1x_2 \le \frac{x_1^2}{2} + \frac{x_2^2}{2}$, we arrive at

$$\begin{aligned} V'(t, x_1, x_2) &= -2\big(x_1^2 + x_2^2(1 + 2e^{-2t})\big) + 2x_1x_2 \\ &\le -(x_1^2 + x_2^2 + 4x_2^2e^{-2t}) \\ &\le -(x_1^2 + x_2^2) := -W_3(|x|). \end{aligned}$$

In addition, if we set

$$W_1(|x|) = \frac{1}{2}(x_1^2 + x_2^2), \;\; W_2(|x|) = x_1^2 + x_2^2,$$

then we have

$$W_1(|x|) \le V(t, x) \le W_2(|x|),$$

and by Theorem 7.1.11, the origin is uniformly asymptotically stable.

Remark 7.2. Theorems 7.1.8–7.1.10 hold for the autonomous system (7.1.11) with autonomous $V(x)$.

7.2 Global asymptotic stability

In this section we briefly discuss the notion of global asymptotic stability.

Definition 7.2.1. Assume that the zero solution of (7.1.11) is stable. If $|x(t, t_0, x_0)| \to 0$ as $t \to \infty$ for every $x(t_0) = x_0$, then we say that the zero solution is *globally asymptotically stable* (GAS).

Remark 7.3. Theorem 7.1.10 implies the zero solution is GAS if $D = \mathbb{R}^n$.
In addition, for the next theorem we note that (7.1.19) implies

$$V(x) \to \infty \;\text{ as }\; ||x|| \to \infty,$$

since $W_1(|x|) \to \infty$ as $|x| \to \infty$.

Example 7.16. Consider the system

$$x_1' = -x_1(1 - 2x_1x_2), \;\; x_2' = -x_2.$$

It is clear that $(0, 0)$ is the only equilibrium solution. Let

$$V(x_1, x_2) = \frac{1}{2}x_1^2 + x_2^2.$$

Then along the solutions we have

$$V'(x_1, x_2) = -x_1^2(1 - 2x_1x_2) - 2x_2^2.$$

Copyright Elsevier 2022

Now $V'(x_1, x_2) < 0$ if $1 - 2x_1x_2 > 0$, that is, if $x_1x_2 < \frac{1}{2}$. Thus the origin is asymptotically stable but not GAS since we are confined to the bounded region that consists of all points (x_1, x_2) such that $x_1x_2 < \frac{1}{2}$. Therefore we cannot conclude that the zero solution is GAS.

We state the following theorem regarding GAS.

Theorem 7.2.1. *Suppose the hypothesis of Theorem 7.1.3 holds with $D = \mathbb{R}^n$. In addition, if $V(x)$ is radially unbounded, that is,*

$$V(x) \to \infty \ \textit{as} \ ||x|| \to \infty, \tag{7.2.1}$$

then the zero solution of (7.1.11) is GAS.

Proof. By Theorem 7.1.2, the zero solution is stable. Suppose there is a solution or trajectory that does not converge to zero. Since V is decreasing and nonnegative, it converges to some γ as $t \to \infty$. Since x does not converge to zero, we have $\gamma \leq V(x(t)) \leq V(x_0)$. Let

$$L = \{z : \gamma \leq V(z) \leq V(x_0)\}.$$

Then L is closed and bounded and hence compact. Therefore V attains its supremum on L, that is, $\sup_{z \in L} V' = -d < 0$, or $V'(x(t)) \leq -d$ for all $t \geq t_0$. An integration of $V' \leq -d$ from 0 to T yields

$$V(x(T)) \leq V(x_0) - dT.$$

This implies that $V(x_0) < 0$ for $T > V(x_0)/d$, which is a contradiction, and hence every trajectory converges to zero. This completes the proof. ☐

Basically, the conditions on V imply that every trajectory $x(t)$ tends to the origin as $t \to \infty$. Since $x(t)$ is continuous, this requires that $x(t)$ remains bounded for all $t \geq t_0$ for arbitrary initial conditions $x(t_0)$. Hence the purpose of the radial unboundedness condition on V is to ensure that $x(t)$ remains at all times within the bounded region defined by $V(x) \leq V(x_0)$. If V were not radially unbounded, then not all level curves given by $V(x) \leq c$ for positive constant c would be closed curves, and it would be possible for $x(t)$ to drift away from the equilibrium even though $V' < 0$.

Example 7.17. The zero solution of the system in Example 7.5 is GAS.

Example 7.18. Consider the system

$$x_1' = (x_2 - 1)x_1^3, \quad x_2' = -\frac{x_1^4}{(1 + x_1^2)^2} - \frac{x_2}{1 + x_2^2}.$$

It is clear that $(0, 0)$ is the only equilibrium solution. Let

$$V(x_1, x_2) = \frac{x_1^2}{1 + x_1^2} + x_2^2.$$

Copyright Elsevier 2022

Then along the solutions we have

$$V'(x_1,x_2) = -2\frac{x_1^4}{(1+x_1^2)^2} - 2\frac{x_2}{1+x_2^2},$$

so that $V(x_1,x_2)$ is a strict Lyapunov function on the set $D=\mathbb{R}^n$, as required by Theorem 7.1.3, and the zero solution is AS. However, V is not radially unbounded since the level curves for $V=c$ are not closed curves for $c \geq 1$. Thus it is not possible to conclude that the zero solution is GAS. Neither is it possible to conclude that the zero solution is *not* GAS without further analysis, since we might find another function V that satisfies all the requirements for the GAS.

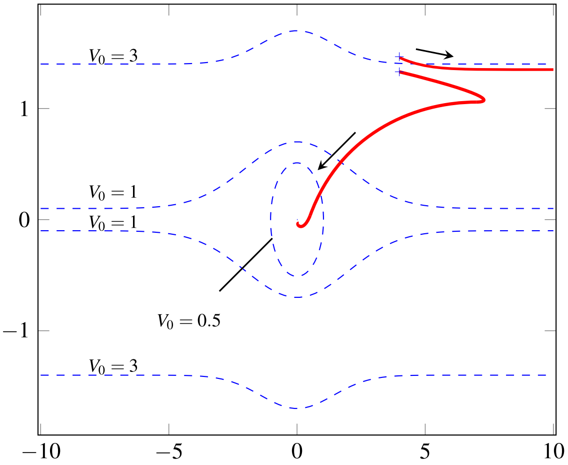

FIGURE 7.2

Level curves escaping to infinity.

As a matter of fact, according to Fig. 7.2, the zero solution is not GAS since solutions escape to infinity with the choice of the initial condition $(x_1(t_0), x_2(t_0)) = (3, 3/2)$.

Remark 7.4. We examine in detail why

$$V(x_1,x_2) = \frac{x_1^2}{1+x_1^2} + x_2^2$$

is not radially unbounded. As mentioned above, the condition that $V(x)$ is radially unbounded means that all level sets are closed. Letting $x_2 = 0$, we try to determine the level set $V(x) = 1$ or $V(x_1, 0) = \dfrac{x_1^2}{1+x_1^2} = 1$, which cannot hold for finite x_1. Thus V is not radially unbounded. Next, we examine the definition of being radially

Copyright Elsevier 2022

unbounded in the context of

$$V(x) \to \infty \text{ as } ||x|| \to \infty.$$

This means that any combinations of x_1, x_2 that make $||x|| \to \infty$ also have to make $V(x) \to \infty$. The Euclidean norm

$$||(x_1, 0)||_2 = \sqrt{x_1^2 + 0^2} = \sqrt{\infty^2 + 0^2} \to \infty.$$

However, in this case, we get for $V(x)$ that

$$\lim_{x_1 \to \infty} V(x_1, 0) = 1 \neq \infty.$$

It follows that V is not radially unbounded.

7.3 Instability

We consider once more the non-autonomous system

$$x' = f(t, x), \quad f(t, 0) = 0, \tag{7.3.1}$$

where $f \in C\big([0, \infty) \times D, \mathbb{R}^n\big)$, and $D \subset \mathbb{R}^n$ is open with $0 \in D$. We have discussed the instability for autonomous systems, but let us recall that if we negate the definition of stability, then there are $\varepsilon > 0$ and $t_0 \geq 0$ such that for any $\delta > 0$, there are x_0 with $|x_0| < \delta$ and $t_1 > t_0$ such that

$$|x(t_1, t_0, x_0)| \geq \varepsilon.$$

Then the zero solution is unstable. We make the following formal definition.

Definition 7.3.1. The zero solution of (7.3.1) is unstable if there are $\varepsilon > 0$ and $t_0 \geq 0$ such that for any $\delta > 0$, there are x_0 with $|x_0| < \delta$ and $t_1 > t_0$ such that $|x(t_1, t_0, x_0)| \geq \varepsilon$.

Theorem 7.3.1. *Suppose* $V : [0, \infty) \times D \to [0, \infty)$ *is a continuous function locally Lipschitz in x such that*

$$W_1(|x|) \leq V(t, x) \leq W_2(|x|), \tag{7.3.2}$$

and along the solutions of (7.3.1) *we have*

$$V'(t, x) \geq W_3(|x|). \tag{7.3.3}$$

Then the zero solution of (7.3.1) *is unstable.*

Copyright Elsevier 2022

Proof. Suppose not. Then for $\varepsilon = \min\{1, d(0, \partial D)\}$, where ∂D denotes the boundary of the set D, we can find $\delta > 0$ such that $|x_0| < \delta$ and $t \geq 0$ imply that $|x(t, 0, x_0)| < \varepsilon$. We may pick x_0 such that $|x_0| = \delta/2$ and find $\gamma > 0$ with $W_2(\gamma) = W_1(\delta/2)$. Then for $x(t) = x(t, 0, x_0)$, we have $V'(t, x) \geq 0$ by (7.3.3), so that

$$W_2(|x(t)|) \geq V(t, x(t)) \geq V(0, x_0) \geq W_1(\delta/2) = W_2(\gamma),$$

from which we conclude that $\gamma \leq |x(t)|$ for $t \geq 0$. Thus

$$V'(t, x) \geq W_3(|x(t)|) \geq W_3(\gamma).$$

It follows that

$$W_2(|x(t)|) \geq V(t, x(t)) \geq V(0, x_0) + tW_3(\gamma),$$

from which we conclude that $|x(t)| \to \infty$, a contradiction. This completes the proof. □

We ask the curious reader to compare condition (7.3.2) with the hypothesis of Theorem 7.1.6 and try to have an appreciation and some understanding of the differences between autonomous systems and non-autonomous systems.

In Theorem 7.3.1 we asked for $|x_0| = \delta/2$, which is too much to ask. This will be relaxed in the next theorem.

Theorem 7.3.2. *Suppose that* $V : [0, \infty) \times D \to (-\infty, \infty)$ *is a continuous function locally Lipschitz in* x *and that there is a sequence* $x_n \in D$ *starting at* $t_0 \geq 0$ *with* $V(t_0, x_n) > 0$ *and* $x_n \to 0$ *as* $n \to \infty$. *If*

$$W_1(|x|) \leq V(t, x) \leq W_2(|x|)$$

and if along the solutions of (7.3.1) *we have*

$$V'(t, x) \geq W_3(|x|),$$

then the zero solution of (7.3.1) *is unstable.*

Proof. Suppose not. Then there are ε and δ as in the proof of Theorem 7.3.1. For δ, we may find t_n and x_n with $|x_n| < \delta$ and $V(t_n, x_n) > 0$. The rest of the proof is identical to that of Theorem 7.3.1. This completes the proof. □

7.4 ω-limit set

We discuss the Krasovskii–LaSalle invariance principle, which provides a way to prove the asymptotic stability when V' is negative *semi-definite*. It is usually much easier to construct such a function V. We begin with the following definition.

Copyright Elsevier 2022

Definition 7.4.1. Let D be an open subset of $\mathbb{R}^n$ with $0 \in D$. A continuous autonomous function $V : D \to [0, \infty)$ is

(a) *positive definite* if

$$V(0) = 0 \text{ and } V(x) > 0 \text{ for } x \neq 0,$$

(b) *positive semi-definite* if

$$V(0) = 0 \text{ and } V(x) \geq 0 \text{ for } x \neq 0.$$

To illustrate the differences, consider the two functions

$$V_1(x) = x_1^2 \text{ and } V_2(x) = x_1^2 + x_2^2.$$

Clearly, both functions are nonnegative. However, it is possible for V_1 to be zero even when $x \neq 0$. Particularly, if we set $x = (0, d)$ where $d \in \mathbb{R}$ is any non-zero number, then $V_1(x) = V_1(0, d) = 0$, whereas $V_2(x) = 0$ if and only if $x = 0$. We conclude that V_1 is positive semi-definite and V_2 is positive definite.

Remark 7.5. If the signs on V' are reversed in Definition 7.4.1, then V is said to be *negative definite* and *negative semi-definite*, respectively.

Let $f : \mathbb{R}^n \to \mathbb{R}^n$ be continuous with continuous first-order partial derivatives with respect to x_i, $i = 1, 2, \ldots, n$. Consider the initial value autonomous system

$$x' = f(x), \; x(t_0) = x_0, \; t \geq t_0. \tag{7.4.1}$$

Let x^* be an equilibrium solution of (7.4.1).

Let $x(t, t_0, x_0)$ be a trajectory of (7.4.1) at time t starting from x_0 at the initial time t_0. Denote the set of all points lying along the trajectory by $x(\cdot, t_0, x_0)$

Definition 7.4.2. (ω-limit set) The *ω-limit set* of a trajectory $x(\cdot, t_0, x_0)$ is the set of all points $z \in \mathbb{R}^n$ such that

$$\lim_{n \to \infty} x(t_n, t_0, x_0) = z,$$

where the sequence t_n is strictly increasing.

Definition 7.4.3. (Invariant set) The set $M \in \mathbb{R}^n$ is said to be an *invariant set* if for all $y \in M$ and $t_0 \geq 0$, we have

$$x(t, t_0, y) \in M \quad \text{for all } t \geq t_0.$$

Theorem 7.4.1. *Let V be a Lyapunov function of* (7.4.1) *on a bounded open set $U \in \mathbb{R}^n$ with $x^* \in U$. Let c be a positive constant, and set*

$$S = \{x \in U : V(x) \leq c\},$$

which is closed in $\mathbb{R}^n$. Then S is invariant for $t \geq t_0 \geq 0$.

Copyright Elsevier 2022

Proof. Let $x \in S$. Since V is a Lyapunov function on U, we have that $V(x(t,t_0,x_0)) \leq V(x_0) \leq c$ for $t \geq t_0 \geq 0$ as long as the solutions exist. Now since S is closed and bounded, the existence of solutions holds for all $t \geq t_0 \geq 0$. As a result, $x(t,t_0,x_0)$ remains in S for all $t \geq t_0 \geq 0$. This shows that the set S is invariant. This completes the proof. □

In Example 7.3 we considered $V(x,y) = x^2 + y^2$ and obtained $V' = 0$. As a result of Theorem 7.4.1, we have that the set

$$S = \{(x,y) \in \mathbb{R}^2 : x^2 + y^2 \leq c\} \text{ for } c > 0$$

is invariant.

Theorem 7.4.2. *(Krasovskii–LaSalle invariance principle) Let D be an open subset of $\mathbb{R}^n$ containing x^*. Let $V : D \to \mathbb{R}$ be a positive definite function such that on the compact set*

$$\Omega_r = \{x \in D : V(x) \leq r, \ \ r > 0\},$$

we have $V'(x) \leq 0$. Define

$$S = \{x \in \Omega_r : V'(x) = 0\}.$$

Then, as $t \to \infty$, the trajectory tends to the largest invariant set inside S, that is, its ω-limit set is contained inside the largest invariant set in S. If S contains no invariant sets other than $x = x^*$, then the equilibrium solution x^* of (7.4.1) is asymptotically stable.

Proof. Let M be the largest invariant set in S, and let L^+ be the ω-limit set for the trajectory $x(t,t_0,x_0)$, which is invariant. Since $V'(x) \leq 0$ and is continuous in Ω_r, we have that $V(x) \geq b = \min_{x \in \Omega_r} V(x) > 0$. Thus there is a positive constant a such that

$$\lim_{t \to \infty} V(x(t,t_0,x_0)) = a.$$

Now $x(t,t_0,x_0) \in \Omega_r$ implies $x(t,t_0,x_0)$ is bounded, which implies that L^+ exists. Moreover, $L^+ \in \Omega_r$, and $x(t,t_0,x_0)$ approaches L^+ as $t \to \infty$. For any $z \in L^+$, there is an increasing sequence $\{t_n\}$ such that

$$\lim_{n \to \infty} x(t_n,t_0,x_0) = z.$$

As $V(x)$ is continuous, we have that

$$V(z) = \lim_{n \to \infty} V(x(t_n,t_0,x_0)) = a.$$

Since $V(x) = a$ on L^+ and L^+ is invariant, we get that $V'(x) = 0$ for all $x \in L^+$ and

$$L^+ \subset M \subset S \subset \Omega_r.$$

Copyright Elsevier 2022

Thus $x(t, t_0, x_0) \to L^+$, and hence $x(t, t_0, x_0) \to M$ as $t \to \infty$. This completes the proof. □

We provide a couple of examples.

Example 7.19. Consider the system

$$x' = y,$$
$$y' = -(x^3 - x^5) - y^3.$$

Let $D = \{(x, y) : x^2 + y^2 \leq 1\}$ and define

$$V(x, y) = \frac{y^2}{2} + \frac{x^4}{4} - \frac{x^6}{6}.$$

Then V is positive definite on D. We can easily verify that $V' = -y^4$. Thus $V' = 0$ along the x-axis, and V' is negative semi-definite. Note that on D, we have $V(x, y) \leq \frac{y^2}{2} + \frac{x^4}{4} \leq \frac{1}{2}(\frac{1}{\sqrt{2}})^2 + \frac{1}{4}(\frac{1}{\sqrt{2}})^4 = \frac{5}{16}$. Thus $\Omega_r = \{(x, y) \in D : \frac{y^2}{2} + \frac{x^4}{4} \leq \frac{5}{16}\}$. Moreover,

$$S = \{(x, y) \in \Omega_r : V'(x) = 0\} = \{(x, y) \in \Omega_r : y = 0\}.$$

Now V is constant only on solutions that lie on the x-axis, but by the uniqueness of solutions, the only such solution is the equilibrium $(0, 0)$. Thus $M = \{(x, y) \in S : x = 0, y = 0\}$ is the largest invariant subset of S. By Theorem 7.4.2, we have that all trajectories in S go to $(0, 0)$ as $t \to \infty$. Note that the other two equilibrium solutions, $(-1, 0)$ and $(1, 0)$, are outside the set Ω_r.

Corollary 7.1. *If the hypotheses of Theorem 7.4.2 hold with $D = \mathbb{R}^n$ and $V(x)$ is radially unbounded, then the origin is GAS.*

Example 7.20. Consider the system

$$x' = y,$$
$$y' = -h_1(x) - h_2(y),$$

where the functions h_1 and h_2 are continuous and satisfy

$$h_i(0) = 0, \;\; uh_i(u) > 0, \;\; i = 1, 2, \;\; \text{for } \; 0 < |u| < a.$$

Let $D = \{(x, y) : |x| < a, \; |y| < a\}$ and set

$$V(x, y) = \frac{y^2}{2} + \int_0^x h_1(s)ds.$$

Copyright Elsevier 2022

Then $V(0,0)=0$ and $V(x,y)>0$ on D. In addition,

$$\begin{aligned} V'(x,y) &= h_1(x)x' + yy' \\ &= h_1(x)y + y\big[-h_1(x) - h_2(y)\big] \\ &= -yh_2(y). \end{aligned}$$

Now $V'(x,y)=0$ implies $yh_2(y)=0$, and hence $y=0$. Thus $V'=0$ along the x-axis, and V' is negative semi-definite. Note that on D, we have

$$V(x,y) \le \frac{a^2}{2} + \int_0^a a\,ds = \frac{3}{2}a^2.$$

Thus $\Omega_a = \{(x,y) \in D : V(x,y) \le \frac{3}{2}a^2\}$. Moreover,

$$S = \{(x,y) \in \Omega_a : V'(x) = 0\} = \{(x,y) \in \Omega_a : y = 0\}.$$

As $y(t)=0$, we have $y'(t)=0$. The second equation of the system gives

$$h_1(x(t)) + h_2(0) = h_1(x(t)) = 0,$$

from which we have $x(t)=0$. Hence the only solution that can stay identically in S is $(x(t),y(t))=(0,0)$, that is, $M=\{(x,y)\in S : x=0,\ y=0\}$ is the largest invariant subset of S. Thus the origin is asymptotically stable by Theorem 7.4.2.

Now we suppose $a=\infty$ and $\displaystyle\int_0^u h_1(s)ds \to \infty$ as $|u|\to\infty$. Then $D=\mathbb{R}^2$, and $V(x,y)=\frac{y^2}{2}+\int_0^x h_1(s)ds$ is radially unbounded. Moreover,

$$S = \{(x,y) \in \Omega_a : V'(x) = 0\} = \{(x,y) \in \Omega_a : y = 0\},$$

and the only solution that can stay identically in S is $(x(t),y(t))=(0,0)$. Thus the origin is GAS. Note that we did not have to worry about the set Ω_a since $a=\infty$ or $D=\mathbb{R}^2$.

We end this section by revisiting the pendulum with friction that we considered in Examples 3.5 and 6.9.

Example 7.21. In Example 3.5 we considered a pendulum with friction and arrived at the planar autonomous system

$$\begin{aligned} x_1' &= x_2, \\ x_2' &= -\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2. \end{aligned} \tag{7.4.2}$$

We are interested in examining the stability of the zero solution by constructing a suitable Lyapunov function. Let $D=\{(x_1,x_2)\in\mathbb{R}^2 : |x_1|<\pi\}$ and set

$$V(x_1,x_2) = \frac{g}{L}\big(1-\cos(x_1)\big) + \frac{1}{2}x_2^2.$$

Copyright Elsevier 2022

Then $V(0,0)=0$, and $V(x_1,x_2)>0$ on $D-(0,0)$. Moreover, along the solutions of (7.4.2) we have

$$\begin{aligned} V'(x_1,x_2) &= \frac{g}{L}\sin(x_1)x_1' + x_2x_2' \\ &= \frac{g}{L}x_2\sin(x_1) + x_2\big(-\frac{g}{L}\sin(x_1) - \frac{b}{m}x_2\big) \\ &= -\frac{k}{m}x_2^2. \end{aligned}$$

Now $V'=0$ along the x_1-axis, and V' is negative semi-definite in D. Let

$$S=\{(x,y)\in D : V'(x)=0\}.$$

As $x_2(t)=0$, this implies that $x_1'(t)=0$, and $x_1(t)$ is constant. Similarly, for $x_2(t)=0$, this implies that $x_2'(t)=0$, and hence $\sin(x_1)=0$. However, the only point on the segment $-\pi<x_1<\pi$ rendering $\sin(x_1)=0$ is $x_1=0$. Hence the only solution that can forever stay in S is $(x_1(t),x_2(t))=(0,0)$. Thus $M=\{(x,y)\in S : x=0, y=0\}$ is the largest invariant subset of S, and the origin is asymptotically stable by Theorem 7.4.2.

Again, there was no need to construct the set Ω_a since $a=\infty$.

We end this section by giving an example in which we expose the difficulties of using Theorem 7.1.3, which requires V to be a strict Lyapunov function, and the advantage of using Theorem 7.4.2. First, we state the following lemma.

Lemma 7.3. *(Young's inequality) For any two nonnegative real numbers w and z, we have*

$$wz \le \frac{w^e}{e} + \frac{z^f}{f} \quad \textit{with } \frac{1}{e}+\frac{1}{f}=1,\ e,f\in(1,\infty).$$

Example 7.22. Consider the autonomous system

$$x'=-y-x^3,\quad y'=x^5.$$

We see that $(0,0)$ is the only equilibrium solution. Let $D=\{(x,y)\in\mathbb{R}^2 : |y|^2\le 1/2\}$ and set

$$V(x,y)=x^6+xy^3+3y^2.$$

We need to show V is a strict Lyapunov function on the set D. Clearly, $V(0,0)=0$. We need to worry about the mixed term xy^3. Let $e=6$ and $f=6/5$. Then by Lemma 7.3, for $|y|\le 1$, we have

$$|xy^3| = |x||y^3| \le \frac{|x|^6}{6} + \frac{5|y|^{18/5}}{6} \le \frac{1}{6}x^6 + \frac{5}{6}y^2.$$

Copyright Elsevier 2022

This implies that

$$3y^2 \geq \frac{18}{5}|xy^3| - \frac{3}{5}x^6.$$

Substituting $3y^2$ into V gives

$$\begin{aligned} V(x, y) &\geq x^6 + xy^3 - \frac{3}{5}x^6 + \frac{18}{5}|xy^3| \\ &= \frac{2}{5}x^6 + xy^3 + |xy^3| + \frac{13}{5}|xy^3| \\ &\geq \frac{2}{5}x^6 + \frac{13}{5}|xy^3|. \end{aligned}$$

Along the solutions of the system we have

$$V'(x, y) = -6x^8 - x^3y^3 + 3x^6y^2 - y^4.$$

Next, we apply Lemma 7.3 to reduce the two mixed terms. Let $(x, y) \in D$. Let $e = 8/3$ and $f = 8/5$. Then

$$|-x^3y^3| = |x^3||y^3| \leq \frac{3|x|^8}{8} + \frac{5|y|^{24/5}}{8} \leq \frac{3}{8}x^8 + \frac{5}{8}y^4,$$

and similarly, if we let $e = 8/6$ and $f = 8/2$, then

$$|3x^6y^2| = 3|x|^6|y|^2 \leq 3[\frac{3|x|^8}{4} + \frac{|y|^8}{4}] = \frac{9}{4}x^8 + \frac{3}{4}y^8.$$

Thus

$$\begin{aligned} V'(x, y) &= -6x^8 + \frac{3}{8}x^8 + \frac{9}{4}x^8 - y^4 + \frac{5}{8}y^4 + \frac{3}{4}y^8 \\ &\leq -\frac{27}{8}x^8 - y^4 + \frac{5}{8}y^4 + \frac{3}{4}y^4(\frac{1}{4}) \\ &= -\frac{27}{8}x^8 - \frac{3}{16}y^4 < 0 \end{aligned}$$

on $D - \{(0, 0)\}$. By Theorem 7.1.3, the zero solution is asymptotically stable. Next, we use Theorem 7.4.2. Let

$$V(x, y) = x^6 + 3y^2.$$

Clearly, $V(0, 0) = 0$, and $V(x, y) > 0$ for $(x, y) \neq (0, 0)$. Moreover,

$$V'(x, y) = -6x^8 \leq 0.$$

Thus $V' = 0$ along the x-axis, and hence V is a Lyapunov function (semi-definite). Here $D = \mathbb{R}^2$, and

$$S = \{(x, y) \in D : V'(x) = 0\}.$$

Copyright Elsevier 2022

As $y = 0$, this implies that $y' = 0$, from which we have $x^5 = 0$, that is, $x = 0$. Thus $M = \{(x, y) \in S : x = 0, y = 0\}$ is the largest invariant subset of S, and the origin is asymptotically stable by Theorem 7.4.2.

7.5 Connection between eigenvalues and Lyapunov functions

Consider the homogeneous system

$$x'(t) = Ax(t), \tag{7.5.1}$$

where A is an $n \times n$ constant matrix. We are interested in relations between the existence of a Lyapunov function for system (7.5.1) and its eigenvalues. It turns out that if all the eigenvalues of A have negative real parts, then there is a strict Lyapunov function. We begin with the following definition.

Definition 7.5.1. Let $x \in \mathbb{R}^n$, and let B be an $n \times n$ constant matrix. We say that B is *positive definite* (*negative definite*) if

$$x^T Bx > 0(< 0) \quad \text{for } x \neq 0.$$

Example 7.23. Let

$$B = I = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 \end{pmatrix} \quad \text{and} \quad x = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}.$$

Then

$$\begin{aligned} x^T Bx &= (x_1, x_2, \dots, x_n) \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} \\ &= x_1^2 + x_2^2 + \ldots + x_n^2 > 0 \quad \text{for } x \neq 0. \end{aligned}$$

Thus the $n \times n$ identity matrix I is positive definite.

To better understand where we are heading, we assume the existence of a positive definite symmetric $n \times n$ constant matrix B and define

$$V(x) = x^T Bx. \tag{7.5.2}$$

Copyright Elsevier 2022

Then $V(x)$ is positive definite, and, moreover, along the solutions of (7.5.1) we have that

$$\begin{aligned} V'(x) &= (x^T)' Bx + x^T Bx' \\ &= (x')^T Bx + x^T Bx' \\ &= (Ax)^T Bx + x^T B(Ax) \\ &= x^T A^T Bx + x^T BAx \\ &= x^T \Big(A^T B + BA\Big) x. \end{aligned} \tag{7.5.3}$$

Notice that

$$\begin{aligned} \Big(A^T B + BA\Big)^T &= B^T A + A^T B^T \\ &= A^T B + BA. \end{aligned}$$

Thus $A^T B + BA$ is symmetric, and so is $A^T B + BA = -C$ for a symmetric matrix C; we wish $-C$ to be negative definite to obtain stability results concerning system (7.5.3).

Remark 7.6. If (7.5.2) holds, then there are positive constants α_1 and α_2 such that

$$\alpha_1 x^T x \le x^T Bx \le \alpha_2 x^T x. \tag{7.5.4}$$

Then $W_1(|x|) = \alpha_1 x^T x$ and $W_2(|x|) = \alpha_2 x^T x$ could serve as two wedges such that

$$\alpha_1 x^T x \le V(x) \le \alpha_2 x^T x.$$

We have the following theorem.

Theorem 7.5.1. *Given an $n \times n$ constant matrix A and a positive definite symmetric matrix C, there exists a positive definite symmetric matrix B such that*

$$A^T B + BA = -C$$

if and only if the zero solution of (7.5.1) *is asymptotically stable.*

Proof. ($\Rightarrow$) Let V be given by (7.5.2) for a positive definite symmetric matrix B. Substituting $A^T B + BA = -C$ into (7.5.3) gives $V'(x) = -x^T Cx < 0$. Then by Theorem 7.1.3, the zero solution is AS.

($\Leftarrow$) Given A, suppose C is symmetric positive definite matrix. Assume that $x = 0$ is AS and let $\Phi(t)$ be the fundamental matrix of (7.5.1). Then by Theorem 4.2.3, there exist positive constants K and α such that

$$||\Phi(t)\Phi^{-1}(s)|| \le Ke^{-\alpha(t-s)}, \ \ t > s.$$

Copyright Elsevier 2022

In particular, $||e^{At}e^{-As}|| \le Ke^{-\alpha(t-s)}$, $t > s$, or

$$||e^{A(t-s)}|| \le Ke^{-\alpha(t-s)}, \quad t > s.$$

Now $\left(e^{A}\right)^{T} = e^{A^T}$, and so the same above estimate holds for $e^{A^T(t-s)}$. Define

$$B(t) = \int_t^\infty e^{A^T(s-t)}Ce^{A(s-t)}ds,$$

which exists since $||e^{At}e^{-As}|| \le Ke^{-\alpha(t-s)}$, $t > s$. Differentiate both sides to get

$$\begin{aligned}\frac{d}{dt}B(t) &= -C - A^T\int_t^\infty e^{A^T(s-t)}Ce^{A(s-t)}ds - \int_t^\infty e^{A^T(s-t)}Ce^{A(s-t)}dsA\\ &= -C - A^TB(t) - B(t)A.\end{aligned}$$

Let $u = s - t$ and rewrite the integral as

$$B(t) = \int_0^\infty e^{A^Tu}Ce^{Au}du,$$

which does not depend on t at all, that is, $\frac{d}{dt}B(t) = 0$, or

$$-C - A^TB(t) - B(t)A = 0.$$

Finally, B is symmetric positive definite because C is. To see this,

$$\begin{aligned}B^T &= \int_0^\infty \left(e^{A^Tu}Ce^{Au}\right)^T du\\ &= \int_0^\infty (e^{Au})^TC^T(e^{A^Tu})^Tdu\\ &= \int_0^\infty e^{A^Tu}Ce^{Au}du = B.\end{aligned}$$

Thus B is symmetric. It remains to show that B is positive definite. Let $x \in \mathbb{R}^n$ and consider the integrand. Then, for each t, we have

$$x^Te^{A^Tt}Ce^{At}x = \left(e^{At}x\right)^TC\left(e^{At}x\right) := y^TCy,$$

and if $x \neq 0$, then $y \neq 0$; hence, as C is positive definite, $y^TCy > 0$ for $x \neq 0$. Thus B is positive definite. This completes the proof. □

In Theorem 5.1.4 we showed if $Re(\sigma(A)) < 0$, then the zero solution of $x' = Ax$ is AS. Thus we may reformulate Theorem 7.5.1 in terms of the eigenvalues of the matrix A.

Copyright Elsevier 2022

Theorem 7.5.2. *Given an $n \times n$ matrix A and a positive definite symmetric matrix C, there exists a positive definite symmetric matrix B such that*

$$A^T B + BA = -C$$

if and only if every eigenvalue of the matrix A has a negative real part.

Example 7.24. Let us find a strict Lyapunov function to show that the zero solution of

$$x' = \begin{pmatrix} -1 & 0 \\ 2 & -3 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ t > 0,$$

is asymptotically stable. Let $A = \begin{pmatrix} -1 & 0 \\ 2 & -3 \end{pmatrix}$. We will find a positive definite symmetric matrix B such that $A^T B + BA = -I$. If $B = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$, then the relation $A^T B + BA = -I$ implies that

$$\begin{pmatrix} -2a + 4b & -4b + 2c \\ -4b + 2c & -6c \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The above equations give $a = \frac{2}{3}$, $b = \frac{1}{12}$, and $c = \frac{1}{6}$. Define

$$\begin{aligned} V(x_1, x_2) = x^T Bx = (x_1 \ \ x_2) \begin{pmatrix} \frac{2}{3} & \frac{1}{12} \\ \frac{1}{12} & \frac{1}{6} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \\ &= \frac{2}{3}x_1^2 + \frac{x_1 x_2}{6} + \frac{x_2^2}{6} \\ &\geq \frac{1}{12}x_1^2 + \frac{x_1 x_2}{6} + \frac{x_2^2}{12} \\ &= \frac{1}{12}(x_1 + x_2)^2. \end{aligned}$$

Thus $V(x_1, x_2)$ is positive definite. On the other hand, after simple calculations, we arrive at

$$\begin{aligned} V'(x_1, x_2) &= -x_1^2 - \frac{2}{3}x_2^2 \\ &\leq -\frac{2}{3}(x_1^2 + x_2^2). \end{aligned}$$

Thus V is a strict Lyapunov function, and by Theorem 7.5.2, the zero solution of the system is AS. We could avoid verifying that V is a strict Lyapunov function and using Theorem 7.5.2 by finding a matrix B satisfying $A^T B + BA = -I$.

Copyright Elsevier 2022

Remark 7.7. To ensure that the symmetric matrix B is positive definite, where $B = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$, it is sufficient for its coefficients to satisfy

$$a > 0, \;\; c > 0, \;\; ac - b^2 > 0.$$

In the investigation of stability and boundedness for nonlinear non-autonomous systems, the effective approach is to study equations related in some way to the linear equations whose behavior is known to be covered by the known theory. We consider the perturbed nonlinear system

$$x'(t) = Ax(t) + g(t, x(t)), \;\; x(t_0) = x_0, \;\; t \geq t_0 \geq 0, \tag{7.5.5}$$

where A is an $n \times n$ constant matrix, and $g : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^n$ is a function continuous in t and x. Here $x = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$ and $g(t, x) = \begin{pmatrix} g_1(t, x) \\ g_2(t, x) \\ \vdots \\ g_n(t, x) \end{pmatrix}$. The perturbation term g is assumed to be small in some sense. The next theorem pertains to the stability of the perturbed nonlinear system (7.5.5).

By $|x|$ we denote the Euclidean norm, and for an $n \times n$ matrix C, by $|C|$ we denote a compatible norm such that $|Cx| \leq |C||x|$.

Theorem 7.5.3. *Suppose there exists a positive definite symmetric matrix B such that*

$$A^T B + BA = -I \tag{7.5.6}$$

and

$$\lim_{x \to 0} \frac{|g(t, x)|}{|x|} = 0 \;\; \textit{uniformly in } t \in [0.\infty). \tag{7.5.7}$$

Then the zero solution of (7.5.5) *is uniformly asymptotically stable.*

Proof. Write x for $x(t)$ and define the function V by

$$V = x^T Bx.$$

Using (7.5.6) and (7.5.7), along the solutions of (7.5.5) we have

$$\begin{aligned} V' &= (Ax + g(t, x))^T B + x^T B(Ax + g(t, x)) \\ &= x^T(-I)x + 2x^T Bg(t, x) \\ &\leq -|x|^2 + 2|x||B||g(t, x)|. \end{aligned}$$

Let $\varepsilon > 0$. Due to (7.5.7), we may choose ε sufficiently small so that for $|x| < \varepsilon$, we have

$$2|B||g(t, x)| < \frac{|x|}{2}.$$

Copyright Elsevier 2022

Thus

$$V' \le -|x|^2 + \frac{|x|^2}{2} = -\frac{|x|^2}{2}.$$

Since B is symmetric and positive definite, there are positive constants α and β such that

$$\alpha^2 x^T x \le V(x) \le \beta^2 x^T x, \tag{7.5.8}$$

from which we get

$$-|x|^2 \le -\frac{1}{\beta^2}V(x) \le -\frac{\alpha^2}{\beta^2}|x|^2.$$

As a consequence,

$$V' \le -\frac{1}{2\beta^2}V(x).$$

An integration of the above inequality from t_0 to t yields

$$V(x(t)) \le V(x_0)e^{-\frac{1}{2\beta^2}(t-t_0)}.$$

We have by (7.5.8)

$$\alpha^2|x|^2 \le V(x) \le V(x_0)e^{-\frac{1}{2\beta^2}(t-t_0)}.$$

It follows that

$$\alpha^2|x|^2 \le x_0^T B x_0 e^{-\frac{1}{2\beta^2}(t-t_0)} \le |x_0^T||B||x_0|e^{-\frac{1}{2\beta^2}(t-t_0)}.$$

For $\varepsilon > 0$ and $|x_0| < \delta$, we have

$$|x| \le \frac{1}{\alpha}(\delta|B|\delta)^{\frac{1}{2}} = \frac{\delta}{\alpha}|B|^{\frac{1}{2}} < \varepsilon$$

for $\delta = \dfrac{\varepsilon\alpha}{|B|^{1/2}}$. Hence the zero solution is uniformly stable. Let $\delta = 1$ from the uniform stability, so that for $|x(t_0)| = |x_0| < \delta$, we need to show that $|x(t)| < \varepsilon$ for $t \ge t_0 + T(\varepsilon)$.

Set $T(\varepsilon) > -4\beta^2 \mathrm{Ln}\left(\frac{\alpha\varepsilon}{|B|^{1/2}}\right)$. Then

$$\begin{aligned} |x| &\le \frac{|B|^{1/2}}{\alpha}e^{-\frac{1}{4\beta^2}(t-t_0)} \\ &\le \frac{|B|^{1/2}}{\alpha}e^{-\frac{1}{4\beta^2}T(\varepsilon)} \\ &< \varepsilon. \end{aligned}$$

This completes the proof. □

Copyright Elsevier 2022

7.6 Exponential stability

We return to the non-autonomous system

$$x' = f(t,x), \quad f(t,0) = 0, \tag{7.6.1}$$

where $f \in C\big([0,\infty) \times D, \mathbb{R}^n\big)$, and $D \subset \mathbb{R}^n$ is an open set with $0 \in D$.

Definition 7.6.1. We say that solutions of system (7.6.1) are *bounded* if any solution $x(t,t_0,x_0)$ of (7.6.1) satisfies

$$\|x(t,t_0,x_0)\| \le C\Big(|x_0|, t_0\Big) \quad \text{for all } t \ge t_0,$$

where $C : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+$ is a constant that depends on t_0 and x_0. We say that solutions of system (7.6.1) are uniformly bounded if C is independent of t_0.

Definition 7.6.2. Suppose $f(t,0) = 0$. We say the zero solution of (7.6.1) is α-*exponentially asymptotically stable* if there exists a continuous function $\alpha(t)$ such that $\int_{t_0}^t \alpha(s)ds \to \infty$ as $t \to \infty$ and constants d and $C \in \mathbb{R}^+$ such that for any solution $x(t,t_0,\varphi)$ of (7.6.1),

$$\|x(t,t_0,\varphi)\| \le C\Big(|\varphi|, t_0\Big)\big(e^{-\int_{t_0}^t \alpha(s)ds}\big)^d \quad \text{for all } t \in [t_0,\infty).$$

The zero solution of (7.6.1) is said to be α-uniformly exponentially asymptotically stable if C is independent of t_0.

Definition 7.6.3. (Exponential stability) The zero solution of system (7.6.1) said to be *exponentially stable* if any solution $x(t,t_0,x_0)$ of (7.6.1) satisfies

$$\|x(t,t_0,x_0)\| \le C\Big(|x_0|, t_0\Big)e^{-d(t-t_0)} \quad \text{for all } t \ge t_0,$$

where d is a positive constant, and $C : [0,\infty) \times [0,\infty) \to [0,\infty)$. The zero solution of (7.6.1) said to be *uniformly exponentially stable* if C is independent of t_0.

Theorem 7.6.1. *Assume that $D \subset \mathbb{R}^n$ and $V : D \to [0,\infty)$ is a continuous function such that for all $(t,x) \in [0,\infty) \times D$,*

$$W_1(||x||) \le V(t,x), \tag{7.6.2}$$

$$V'(t,x) \le -\alpha(t)V^q(t,x) + \beta(t), \tag{7.6.3}$$

$$0 \le V(t,x) - V^q(t,x) \le \gamma(t), \tag{7.6.4}$$

where $\alpha(t)$, $\gamma(t)$, and $\beta(t)$ are nonnegative continuous functions, and p, q are positive constants. Then all solutions of (7.6.1) that start in D satisfy

Copyright Elsevier 2022

$$\begin{aligned}||x|| \le W_1^{-1}\Big\{ & V(t_0, x_0)e^{-\int_{t_0}^{t}\alpha(s)ds} \\ & + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\, e^{-\int_u^t \alpha(s)ds}\, du\Big\}\end{aligned} \tag{7.6.5}$$

for all $t \ge t_0$.

In case $q = 1$, the proof is a simple application of the variation of parameters formula. On the other hand, if $q \neq 1$, then the variation of parameters formula will not be of much help. Now we prove the theorem.

Proof. For any initial time $t_0 \ge 0$ and $x_0 \in D$, let $x(t, t_0, x_0)$ be a solution of (7.6.1) with $x_{t_0} = x_0$. Consider

$$\begin{aligned}\frac{d}{dt}\Big(e^{\int_{t_0}^{t}\alpha(s)ds}V(t,x)\Big) &= \Big[V'(t,x)+\alpha(t)V(t,x)\Big]e^{\int_{t_0}^{t}\alpha(s)ds} \\ &\le \Big(-\alpha(t)V^q(t,x)+\beta(t)+\alpha(t)V(t,x)\Big)e^{\int_{t_0}^{t}\alpha(s)ds} \\ &\le \Big(\alpha(t)(V(t,x)-V^q(t,x))+\beta(t)\Big)e^{\int_{t_0}^{t}\alpha(s)ds} \\ &\le \Big(\alpha(t)\gamma(t)+\beta(t)\Big)e^{\int_{t_0}^{t}\alpha(s)ds}.\end{aligned}$$

Integrating both sides from t_0 to t, we obtain, for $t \in [t_0, \infty)$,

$$\begin{aligned}V(t,x)e^{\int_{t_0}^{t}\alpha(s)ds} \le\; & V(t_0, x_0) \\ & + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\, e^{\int_{t_0}^{u}\alpha(s)ds}\, du.\end{aligned} \tag{7.6.6}$$

It follows that

$$V(t,x) \le V(t_0,x_0)e^{-\int_{t_0}^{t}\alpha(s)ds} + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\, e^{-\int_u^t \alpha(s)ds}\, du$$

for all $t \in [t_0, \infty)$. Inequality (7.6.2) implies that

$$||x(t)|| \le W^{-1}\Big\{V(t_0,x_0)e^{-\int_{t_0}^{t}\alpha(s)ds} + \int_{t_0}^{t}\Big(\gamma\alpha(u)+\beta(u)\Big)\, e^{-\int_u^t \alpha(s)ds}\, du\Big\}$$

for all $t \ge t_0$. This concludes the proof. □

It is easy to see that if $W_1(||x||) = ||x||^p$ for some positive p, then inequality (7.6.5) becomes

$$\begin{aligned}||x|| \le \Big\{ & V(t_0, x_0)e^{-\int_{t_0}^{t}\alpha(s)ds} \\ & + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\, e^{-\int_u^t \alpha(s)ds}\, du\Big\}^{1/p}.\end{aligned} \tag{7.6.7}$$

Copyright Elsevier 2022

Corollary 7.2. *Assume that the hypotheses of Theorem 7.6.1 hold.*

(i) If

$$\int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\,e^{-\int_u^t \alpha(s)ds}\,du \le M, \forall t \ge t_0 \ge 0, \tag{7.6.8}$$

for some positive constant M, then all solutions of (7.6.1) are uniformly bounded.

(ii) If

$$\int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\,e^{\int_{t_0}^u \alpha(s)ds}\,du \le M \tag{7.6.9}$$

for some positive constant M, and

$$\int_{t_0}^{t}\alpha(s)ds \to \infty \;\; as \;\; t\to\infty \;\; for\ all \;\; t \ge t_0, \tag{7.6.10}$$

then every solution of solution (7.6.1) decays α-exponentially asymptotically to zero with $d = 1/p$.

(iii) If

$$f(t,0)=0$$

and (7.6.9) holds for q positive constant α, then the zero solution of (7.6.1) is exponentially stable.

Proof. Let x be a solution to (7.6.1) that starts in D for all $t \ge t_0 \ge 0$. Consequently, the proof of *(i)* is an immediate consequence of inequality (7.6.7). For the proof of *(ii)*, we consider the inequality from the proof of Theorem 7.6.1

$$V(t,x_t)e^{\int_{t_0}^t \alpha(s)ds} \le V(t_0,x_0) + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\,e^{\int_{t_0}^u \alpha(s)ds}\,du$$

for all $t \in [t_0,\infty)$. This yields

$$V(t,x_t) \le \Big[V(t_0,x_0) + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\,e^{\int_{t_0}^u \alpha(s)ds}\,du\Big]e^{-\int_{t_0}^t \alpha(s)ds}$$

for all $t \in [t_0,\infty)$. Using $W_1(||x||) = ||x||^p$, we have

$$|x| \le \Big[V(t_0,x_0) + \int_{t_0}^{t}\Big(\gamma(u)\alpha(u)+\beta(u)\Big)\,e^{\int_{t_0}^u \alpha(s)ds}\,du\Big]^{1/p} e^{-\frac{1}{p}\int_{t_0}^t \alpha(s)ds}. \tag{7.6.11}$$

The proof of *(iii)* is an immediate consequence of inequality (7.6.11). This completes the proof. □

Remark 7.8. If $f(t,0) \neq 0$ and (7.6.9) and (7.6.10) hold, then all solutions of (7.6.1) decay exponentially to zero.

Copyright Elsevier 2022

Example 7.25. For $a(t), b(t), h(t) \geq 0$, consider the scalar differential equation

$$x'(t) = -\big(a(t) + \frac{7}{6}\big)x(t) + b(t)x^{\frac{1}{3}}(t) + h(t) \quad t \geq t_0 \geq 0, \tag{7.6.12}$$

with initial condition $x(t_0) = x_0 \in \mathbb{R}$. Let $V(t,x) = x^2$. Then along any solution $x := x(t)$ of (7.6.12), we have

$$\begin{aligned} V'(t,x) &= 2xx' \\ &= -2\big(a(t) + \frac{7}{6}\big)x^2 + 2b(t)x^{4/3} + 2xh(t) \\ &\leq -2\big(a(t) + \frac{7}{6}\big)x^2 + 2b(t)x^{4/3} + x^2 + h^2(t). \end{aligned}$$

To further simplify $V'(t,x)$, we use Young's inequality, which says for any two nonnegative real numbers w and z, we have

$$wz \leq \frac{w^e}{e} + \frac{z^f}{f} \quad \text{with } \frac{1}{e} + \frac{1}{f} = 1.$$

Thus for $e = 3/2$ and $f = 3$, we obtain

$$2|b(t)|x^{4/3} \leq 2\Big[\frac{1}{3}|b(t)|^3 + \frac{(x^{4/3})^{3/2}}{3/2}\Big] = \frac{4}{3}x^2 + \frac{2}{3}|b(t)|^3.$$

As a result, we have

$$V'(t,x) \leq -2a(t)x^2 + \frac{2}{3}b^3(t) + h^2(t). \tag{7.6.13}$$

It follows that

$$V'(t,x) \leq -\alpha(t)x^2 + \beta(t), \tag{7.6.14}$$

where $\alpha(t) = 2a(t)$ and $\beta(t) = \frac{2}{3}b^3(t) + h^2(t)$. We can easily check that conditions (7.6.2)–(7.6.4) of Theorem 7.6.1 are satisfied with $W_1(|x|) = x^2$, $q = 2$, and $\gamma = 0$. Next, we choose some convenient values for our variables.

Let $a(t) = \frac{t}{2}$, $b(t) = t^{\frac{1}{3}}$, and $h(t) = t^{1/2}$. Then $\alpha(t) = t$, $\beta(t) = \frac{5}{3}t$, and (7.6.14) becomes $V'(t,x) \leq -tx^2 + \frac{5}{3}t$. We note that

$$\begin{aligned} \int_{t_0}^{t} \big(\gamma\alpha(u) + \beta(u)\big)e^{-\int_u^t \alpha(s)ds}\, du &= \frac{5}{3}\int_{t_0}^{t} ue^{-\int_u^t s ds}\, du \\ &\leq \frac{5}{3}, \end{aligned}$$

for all $t \geq t_0 \geq 0$. Thus condition (7.6.8) holds. By Corollary 7.2 all solutions of

$$x'(t) = -\big(\frac{t}{2} + \frac{7}{6}\big)x(t) + t^{\frac{1}{3}}x^{\frac{1}{3}}(t) + t^{1/2}, \; x(t_0) = x_0, \; t \geq t_0 \geq 0, \tag{7.6.15}$$

are uniformly bounded.

Copyright Elsevier 2022

On the other hand, if we take $a(t) = 1/2$, $b(t) = e^{-\kappa_1 t/3}$, and $h(t) = 0$, where $\kappa_1 > 1$, then we have $\alpha(t) = 1$, $\beta(t) = \frac{2}{3}e^{-\kappa_1 t}$, and

$$\begin{aligned}\int_{t_0}^{t} \big(\gamma\alpha(u) + \beta(u)\big)e^{\int_{t_0}^{u}\alpha(s)\,ds}\,du &= \int_{t_0}^{t} \frac{2}{3}e^{-\kappa_1 u}e^{\int_{t_0}^{u} ds}\,du \\ &\leq \frac{2}{3(\kappa_1 - 1)}e^{t_0(1-\kappa_1)}\end{aligned}$$

for all $t \geq t_0 \geq 0$. Hence condition (7.6.9) is satisfied. Finally, (7.6.11) gives the inequality

$$\begin{aligned}|x(t)| &\leq \big(x_0^2 + \frac{2}{3(\kappa_1 - 1)}e^{t_0(1-\kappa_1)}\big)e^{\kappa_1(t-t_0)} \\ &\leq \big(x_0^2 + \frac{2}{3(\kappa_1 - 1)}\big)e^{\kappa_1(t-t_0)},\end{aligned}$$

from which we arrive at the uniform exponential stability of the zero solution of

$$x'(t) = -\frac{5}{3}x(t) + e^{-\frac{\kappa_1}{3}t}x^{\frac{1}{3}}(t), \;\; x(t_0) = x_0, \; t \geq t_0 \geq 0.$$

7.7 Exercises

Exercise 7.1. Use Lyapunov function to investigate the stability of the origin for each of the following systems and compare with the linearization method:
(a) $x' = y$, $y' = -x$.
(b) $x' = -xy^2$, $y' = 3yx^2$.
(c) $x' = y - 2x$, $y' = 2x - y - x^3$.
(d) $x' = x + 3y$, $y' = 2x$.
(e) $x' = x^3 + y$, $y' = x + y^3$.
(f) $x' = y$, $y' = -x - y - x^3$.

Exercise 7.2. Find the two equilibrium solutions and use Lyapunov functions to investigate their stability of

$$x' = y - x^2, \;\; y' = x - y^2.$$

Exercise 7.3. Consider the planar system

$$\begin{aligned}x' &= -xy^2, \\ y' &= -y - yx^2.\end{aligned}$$

Examine the stability of the origin using:
(a) Theorem 6.2.1,
(b) a Lyapunov function.

Copyright Elsevier 2022

Exercise 7.4. Consider the planar system

$$\begin{aligned} x' &= ax(x+y) - xy^3, \\ y' &= ay(x+y) + x^2y^2. \end{aligned}$$

Examine the stability of the origin for different values of a using:
(a) a Lyapunov function,
(b) the linearization method.

Exercise 7.5. Put the differential equation

$$x'' + (x')^2 + x' + x(x-2) = 0$$

into a system and find its two equilibrium solutions and examine their stability using:
(a) a Lyapunov function,
(b) the linearization method.

Exercise 7.6. Use the indicated Lyapunov function V and Theorem 7.1.4 to show that the origin is asymptotically stable. Show that all solutions tend to the origin as $t \to \infty$.
(a) $x' = 2y$, $y' = -3x - 3y^3$, $V = 3x^2 + 2y^2$.
(b) $x' = -x + 6y$, $y' = -x - 2y$, $V = x^2 + 2y^2$.
(c) $x' = -2x - y$, $y' = 6x - y$, $V = 2x^2 + y^2$.
(d) $x' = y$, $y' = -x^2y - x^3$, $V = x^4 + 2y^2$.

Exercise 7.7. Study the stability of the origin for the planar system

$$\begin{aligned} x' &= x(y-1), \\ y' &= -\frac{x^2}{1+x^2}, \end{aligned}$$

by considering the Lyapunov function $V(x, y) = \mathrm{Ln}(1 + x^2) + y^2$.

Exercise 7.8. Use a Lyapunov function to show the existence of a stable limit cycle for the system

$$x' = y + x(\mu^2 - x^2 - y^2), \quad y' = -x + y(\mu^2 - x^2 - y^2)$$

for $\mu \neq 0$.

Exercise 7.9. Consider the planar system

$$x' = x + g_1(x, y), \quad y' = -y + g_2(x, y),$$

where g_1 and g_2 are continuous on a subset D of $\mathbb{R}^2$ that contains $(0, 0)$. Suppose that for a positive constant k,

$$||g_i|| \leq k(x^2 + y^2), i = 1, 2,$$

with $g_1(0, 0) = g_2(0, 0) = 0$. Use Theorem 7.1.6 to show that the origin is unstable.

Copyright Elsevier 2022

Exercise 7.10. Consider the second-order differential equation

$$x'' + g(x) = 0,$$

where g is continuously differentiable, $g(0) = 0$, and $xg(x) > 0$. Write the equation as a system and use a Lyapunov function to show that its zero solution is stable.

Exercise 7.11. Consider the second-order differential equation

$$x'' + f(x)x' + g(x) = 0,$$

where $f(x)$ and $g(x)$ are even and odd polynomials, respectively.
(a) Show that the equation is equivalent to the system

$$x' = y - F(x), \quad y' = g(x),$$

where $F(x) = \int_0^x f(s)ds$.
(b) Let $G(x) = \displaystyle\int_0^x g(s)ds$ and suppose there are positive constants α and β such that $g(x)F(x) > 0$ for $0 \le |x| < \alpha$ and $G(x) < \beta$ for $|x| < \alpha$.

Show that

$$V(x, y) = \frac{y^2}{2} + G(x)$$

is a Lyapunov function in the region $A = \{\alpha, \beta \in \mathbb{R} : |x| < \alpha, y^2 < \beta\}$ and that the origin is asymptotically stable.

Exercise 7.12. Consider the predator–prey model with carrying capacity

$$x' = x[a - dx - by], \quad y' = y[-c + kx],$$

where $x(t)$ and $y(t)$ are the numbers of preys and predators at time t, respectively, with positive constants a, b, c, d, and k.
(a) Find the equilibrium point (x^*, y^*) located in the first quadrant.
(b) Use the transformation

$$u = \mathrm{Ln}(\frac{x}{x^*}) \text{ and } v = \mathrm{Ln}(\frac{y}{y^*})$$

to obtain a system in (u, v).
(c) Show that

$$V(u, v) = kx^*(e^u - u) + by^*(e^v - v) - kx^* - by^*$$

is a Lyapunov function and that the equilibrium solution (x^*, y^*) is stable.

Exercise 7.13. Prove Theorem 7.1.7.

Copyright Elsevier 2022

Exercise 7.14. Consider the second-order differential equation

$$x'' + (\mu + \nu x^2)x' + x + x^3 = 0$$

(a) If $\nu = 0$ and $\mu > 0$, then show that the zero solution is asymptotically stable.
(b) If $\mu = 0$ and $\nu > 0$, then show that the zero solution is stable using an appropriate Lyapunov function.

Exercise 7.15. Consider the planar system

$$\begin{aligned} x' &= (x - by)(x^2 + y^2 - 1), \\ y' &= (ax + y)(x^2 + y^2 - 1). \end{aligned}$$

Show that the origin is stable if $a, b > 0$.

Exercise 7.16. Show that the origin is unstable for the planar system

$$\begin{aligned} x' &= x + y, \\ y' &= x - y + xy. \end{aligned}$$

Exercise 7.17. Suppose f is continuously differentiable and consider the planar system

$$\begin{aligned} x' &= y - xf(x, y), \\ y' &= -x - yf(x, y). \end{aligned}$$

Show that the origin is asymptotically stable if $f(x, y) > 0$ and unstable if $f(x, y) < 0$.

Exercise 7.18. Let $V = x^2 + y^2$ and consider the system

$$\begin{aligned} x' &= (x - y)(x^2 + y^2 - 1), \\ y' &= (x + y)(x^2 + y^2 - 1). \end{aligned}$$

Show that the origin is asymptotically stable and find the region of attraction.

Exercise 7.19. Let $V = x^2 + y^2$ and consider the system

$$\begin{aligned} x' &= -x + 2x^2 + y^2, \\ y' &= -y + y^2. \end{aligned}$$

Show that the origin is asymptotically stable and find the region of attraction.

Exercise 7.20. Let $V = x^2 + y^4$ and consider the system

$$\begin{aligned} x' &= -x + 2y^3 - 2y^4, \\ y' &= -x - y + xy. \end{aligned}$$

Show that the origin is globally asymptotically stable.

Copyright Elsevier 2022

Exercise 7.21. Let $V = ax^{2m} + by^{2m}$, $a, b > 0$ and consider the system

$$\begin{aligned} x' &= -3x^3 - y, \\ y' &= -x^5 - 2y^3. \end{aligned}$$

Determine the values of a, b, m, and n, where m and n are positive integers, such that the origin is globally asymptotically stable.

Exercise 7.22. Decide if the functions given below are radially unbounded or not.
(a)

$$V(x_1, x_2) = (x_1 - x_2)^2.$$

(b)

$$V(x_1, x_2) = \frac{x_1^2 + x_2^2}{1 + x_1^2 + x_2^2} + (x_1 - x_2)^2.$$

Exercise 7.23. Consider the equation

$$y'' + By' + y + y^3 = 0, \quad B \geq 0,$$

which is a particular case of mass-spring nonlinear damper.
(a) Use the transformation $v = y'$ and obtain a corresponding system in y and v.
(b) Show that

$$V(y, v) = \frac{y^2 + y^4}{2} + \frac{v^2}{2}$$

is a Lyapunov function.
(c) Decide whether the origin is stable or asymptotically stable.

Exercise 7.24. Consider the non-autonomous system

$$\begin{aligned} x' &= -x - g(t)y, \\ y' &= x - y, \end{aligned}$$

where $g(t)$ is continuously differentiable and, for positive constants k_1, k_2, satisfies

$$k_1 \leq g(t) \leq k_2 \quad \text{and} \quad g'(t) \leq g(t)$$

for all $t \geq 0$. Use a Lyapunov function to show that the zero solution is uniformly stable.

Exercise 7.25. Consider the scalar non-autonomous differential equation

$$x' = -\Big(1 + g(t)\Big)x^3,$$

Copyright Elsevier 2022

where $g(t)$ is continuous, and

$$g(t) \geq 0 \quad \text{for all} \quad t \geq 0.$$

Use a Lyapunov function to show that the zero solution is uniformly asymptotically stable.

Exercise 7.26. Let $D = \{x \in \mathbb{R}^n : |x| \leq \delta\}$ for $\delta > 0$, and let $V(t, x) : [0, \infty) \times D \to [0, \infty)$ be a continuously differentiable function satisfying

$$V(t, 0) = 0,$$
$$W_1(|x|) \leq V(t, x) \leq W_2(|x|),$$

and

$$V'(t, x) \leq -W_3(V(t, x)) \ \text{ for all } \ t \geq 0, \ |x| \leq \delta.$$

Show that the zero solution of (7.1.17) is uniformly asymptotically stable.

Exercise 7.27. Put the scalar equation

$$x'' - x^3$$

into a system and find a function that satisfies the requirements of Theorem 7.3.1.

Exercise 7.28. Write the scalar equation

$$x'' + f(x') + g(x) = 0$$

as a system. Assume that

$$xf(x') > 0, \ \ x' \neq 0, \ \text{ and } \ xg(x) > 0, \ \ x \neq 0.$$

Use Theorem 7.3.1 to show that the origin is asymptotically stable.

Exercise 7.29. Use Exercise 7.28 to show that the zero solutions of given differential equations are asymptotically stable.
(a) $x'' + x'|x'| + x - \frac{x^3}{3} = 0$.
(b) $x'' + (x')^3 + x^5 - x^4 \sin^2(x) = 0$.

Exercise 7.30. Consider the system

$$x_1' = -x_1 + g(x_2),$$
$$x_2' = -x_2 + h(x_1),$$

where g and h are continuous and satisfy

$$|g(u)| \leq |u|/2, \ \ |h(u)| \leq |u|/2.$$

Use the Lyapunov function $V(x_1, x_2) = \frac{1}{2}(x_1^2 + x_2^2)$ to show that the origin is uniformly exponentially stable.

Copyright Elsevier 2022

Exercise 7.31. Let $C = I$ and $A = \begin{pmatrix} 0 & 1 \\ -2 & -3 \end{pmatrix}$. Find a symmetric matrix B such that $A^T B + BA = -I$.

Exercise 7.32. Let B be chosen from Exercise 7.31 and set $V = x^T Bx$. Show that V is an autonomous Lyapunov function in some open set D containing $x = 0$ for the system

$$\begin{aligned} x_1' &= x_2 + f_1(t, x), \\ x_2' &= -2x_1 - 3x_2 + f(t, x), \end{aligned}$$

where

$$\lim_{|x| \to 0} \frac{|f_i(t, x)|}{|x|} = 0, \; i = 1, 2,$$

uniformly for $t \in [0, \infty) \times B_1(0)$. Then find a wedge W such that $V'(x) \leq -W(|x|)$ on D.

Exercise 7.33. Consider the pendulum of Example 7.21 and define the function

$$V(x_1, x_2) = \frac{g}{L}\big(1 - \cos(x_1)\big) + \frac{1}{2}x^T Bx$$

with positive definite matrix B that is to be found.
Hint: See Remark 7.7 and then compute V' along the solutions. Pick the entries of B to ensure that V is a strict Lyapunov function on the set $D - \{(0, 0)\}$.

Exercise 7.34. Use Theorem 7.4.2 to show that the zero solution is asymptotically stable for

$$x' = -x^3 + 2y^3, \quad y' = -2xy^2.$$

Hint: See Example 7.22.

Exercise 7.35. (Harmonic oscillator) Let

$$x'' + \sin(x) = 0.$$

(a) Can you prove the stability of the origin using linearization? Use an appropriate Lyapunov function to show that the origin is a stable equilibrium solution.
(b) Add the damping term

$$x'' + \varepsilon x' + \sin(x) = 0.$$

Study the stability of the origin for $\varepsilon > 0$.

Exercise 7.36. Let $x(t) = (x_1(t), x_2(t))^T \in \mathbb{R}^2$ and consider

$$\begin{aligned} x_1'(t) &= x_2(t) - x_1(t)|x_1(t)|, \\ x_2'(t) &= -x_1(t) - x_2(t)|x_2(t)| \end{aligned}$$

Copyright Elsevier 2022

with initial condition $x(t_0) = x_0 \in \mathbb{R}^2$. Set $D = \{(x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 \le \frac{8}{9}\}$. Let $V : [0, \infty) \times D \to [0, \infty)$ be given by $V(t, x) = \frac{1}{2}(x_1^2 + x_2^2)$. Show that:

(a)

$$V'(t, x) \le -2V^{3/2}(t, x);$$

(b)

$$V(t, x) - V^q(t, x) = V(t, x) - V^{3/2}(t, x) \le \frac{4}{27};$$

for $(x_1, x_2) \in D$.

(c) Refer to a specific theorem in the text to conclude that the zero solution is uniformly exponentially stable for any $x_0 \in D$.

(d) Explain why linearization around the origin cannot be used here.

Hint: Use the inequality

$$\Big(\frac{a+b}{2}\Big)^e \le \frac{a^e}{2} + \frac{b^e}{2}, a, b > 0, e > 1.$$

Exercise 7.37. Let $x(t) = (x_1(t), x_2(t))^T \in \mathbb{R}^2$ and consider

$$x_1'(t) = x_2 - g(t)x_1(x_1^2 + x_2^2),$$

$$x_2'(t) = -x_1 - g(t)x_2(x_1^2 + x_2^2)$$

with initial condition $x(t_0) = x_0 \in \mathbb{R}^2$, where $g(t)$ is continuously differentiable and bounded, and $g(t) \ge k > 0$ for all $t \ge 0$. Set $D = \{(x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 \le 1\}$. Let $V : [0, \infty) \times D \to [0, \infty)$ be given by $V(t, x) = \frac{1}{2}(x_1^2 + x_2^2)$. Show that the hypotheses of Theorem 7.6.1 are satisfied for $(x_1, x_2) \in D$ and conclude that the zero solution is uniformly exponentially stable for any $x_0 \in D$.

Exercise 7.38. Consider

$$\begin{aligned} x_1'(t) &= x_2 + x_1x_3, \\ x_2'(t) &= -x_1 - x_2 + x_2x_3, \\ x_3'(t) &= -x_1^2 - x_2^2. \end{aligned}$$

Use Theorem 7.4.2 to show that

$$x_1(t),\ x_2(t) \to 0 \text{ as } t \to \infty, \text{ and } x_3(t) \to c \text{ as } t \to \infty,$$

for some constant c.

Exercise 7.39. Repeat Example 7.24 for the system

$$x' = \begin{pmatrix} -1 & 0 \\ 1 & -2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ t > 0.$$

Copyright Elsevier 2022

Exercise 7.40. Consider the SIR epidemic model of Section 6.3 and let

$$T = \{(S, I) : S \geq 0, I \geq 0, \ S + I < 1\}.$$

Define the function V on T by

$$V(S, I) = S - S^* - S^* \mathrm{Ln}(\frac{S}{S^*}) + I - I^* - I^* \mathrm{Ln}(\frac{I}{I^*}).$$

(a) Show that along the solutions we have

$$V'(S, I) \leq -\mu \frac{(S - S^*)^2}{SS^*}.$$

(b) Show that V is positive definite on T.
Hint: Clearly, $V(S^*, I^*) = 0$. To show that $V(S, I) > 0$ for $(S, I) \neq (S^*, I^*)$, consider the function

$$f(x) = x - x^* - x^* \mathrm{Ln}(\frac{x}{x^*}), \ 0 < x < 1, \ 0 < x^* < 1$$

and show it has a minimum of zero at x^* and $f(x) > 0$ for $x \neq x^*$.

(c) Use Theorem 7.4.2 to conclude that (S^*, I^*) is asymptotically stable.

Exercise 7.41. Consider the Lorenz system

$$\begin{aligned} x'(t) &= \rho(y - x), \\ y'(t) &= rx - y - xz, \\ z'(t) &= xy - bz, \end{aligned}$$

where ρ, r, and b are positive constants.
1) Show that, for $0 < r < 1$, the origin $(0, 0, 0)$ is the only equilibrium solution.
2) Let

$$V(x, y, z) = \frac{1}{2\rho}\left(x^2 + \rho y^2 + \rho z^2\right).$$

Show that the origin $(0, 0, 0)$ is asymptotically stable for $0 < r < 1$.

CHAPTER

Delay differential equations

8

This chapter is introductory to the study of *delay differential equations*. We will touch on the existence and uniqueness of solutions and stability using the Lyapunov method. Toward the end of the chapter, we use the fixed point theory on Banach spaces developed in Chapter 2 to deduce boundedness and stability results for neutral delay differential equations. We end the chapter by utilizing Lyapunov functionals and obtain the exponential stability for totally nonlinear finite delay integro-differential equations.

8.1 Introduction

Delay differential equations are a type of equation in which the derivative of the unknown function at a certain time is given in terms of the values of the function at previous times. In the previous seven chapters, we considered finite-dimensional differential systems, where the state at any time can be obtained from a finite set of values. On the other hand, delay differential equations are *infinite-dimensional systems*. As a consequence, delay differential equations present us with some difficulties when we analyze them. Nevertheless, some known theories for differential equations can be extended to cover delay differential equations.

For the moment, we consider the scalar delay differential equation

$$x' = f(t, x(t), x(t-\tau)), \tag{8.1.1}$$

where τ is a positive constant known as the delay. If we set $t = 0$ in (8.1.1), then we must know the value of the dependent variable x at s, where $-\tau \le s \le 0$, that is, we need to define an initial function $\varphi : [-\tau, 0] \to \mathbb{R}$. In other words, the initial function φ gives the behavior of the system prior to time 0 (assuming that we start at time $t = 0$). In general, for system (8.1.1) to be *well posed*, we must specify an initial function and work with the delay system

$$x' = f(t, x(t), x(t-\tau)), \quad 0 \le t_0 \le t \le t_f, \tag{8.1.2}$$

$$x(s) = \varphi(s), \quad -\tau \le s \le t_0 \le 0,$$

where $f : [t_0, t_f] \times \mathbb{R}^2 \to \mathbb{R}$. Note that system (8.1.2) is referred to as a delay differential equation with finite delay.

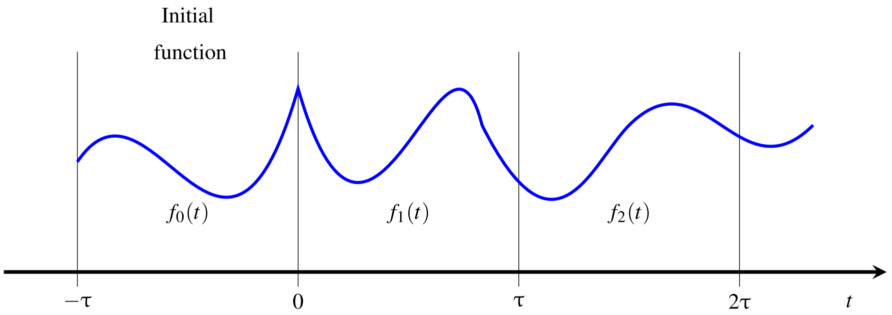

FIGURE 8.1

The effect of the initial function and the delay and the solution space.

Definition 8.1.1. We say that $x : [t_0 - \tau, t_f] \to \mathbb{R}$ is a solution of (8.1.2) if it is continuous and satisfies (8.1.2) for $t_0 \le t \le t_f$ and $x(s) = \varphi(s)$, $-\tau \le s \le t_0$. If every two solutions of (8.1.2) agree with each other as far as both are defined, then the solution is said to be *unique*.

We may think of the solution of (8.1.2) as a mapping from functions on the interval $[t - \tau, t]$ into functions on the interval $[t, t + \tau]$. In other words, the solutions can be thought of as a sequence of functions $f_0(t), f_1(t), f_2(t), \ldots$ defined over intervals of length τ. The points $t = j\tau$, $j = 0, 1, 2, \ldots$, where the solution segments meet are called knots. Fig. 8.1 illustrates this mapping.

It is to be understood that $x'(t_0)$ is the *right-hand derivative* of x at t_0. In most cases the solution is not differentiable at $t = t_0$ as seen in Fig. 8.1. In the case of differential equations, we only have to give an initial condition at a single point, known as the initial time.

For the delay system (8.1.2), we had to specify an initial function on the whole interval $[-\tau, t_0]$, $t_0 \le 0$. The system inherits being infinite-dimensional from the fact that the initial function takes infinitely many values at infinitely many points in the interval $[-\tau, t_0]$.

There are different types of delay differential equations:

$$x' = f(t, x(t), x(t - \tau_1), \ldots, x(t - \tau_m)), \quad 0 \le t_0 \le t \le t_f, \tag{8.1.3}$$

$$x(s) = \varphi(s), \quad -\tau \le s \le t_0 \le 0,$$

where $\tau = \max\{\tau_j,\ 1 \le j \le m\}$. We can try to solve (8.1.3) for $0 \le t_0 \le t \le t_0 + r$, where $r = \min\{\tau_j,\ 1 \le j \le m\}$. System (8.1.3) is known as a differential equation with *multiple delays*. For (8.1.3), the initial function $\varphi : [-\tau, t_0] \to \mathbb{R}^m$, $t_0 \le 0$. On the other hand, if $a(t)$ is a continuous function with $a : [0, \infty) \to (-\infty, \infty)$, then the system

Copyright Elsevier 2022

$$x' = a(t)x(t) + \int_{-\infty}^{t} f(s, x(s))ds, \quad 0 \le t_0 \le t \le t_f, \tag{8.1.4}$$

$$x(s) = \varphi(s), \ \ -\infty < s \le t_0 \le 0$$

is referred to as a *Volterra integro-differential equation with infinite delay*. System (8.1.4) is called a *Volterra integro-differential equation with finite delay* if the lower limit of integration is $t - \tau$, where $\tau > 0$, instead of $-\infty$. In this case the initial function is the same as in (8.1.2). Others may refer to it as a *Volterra integro-differential equation with distributed delay*. Finally, if the delay τ of system (8.1.2) depends on time, then the system is referred to as a *delay differential equation with time-varying delay or functional delay*.

8.2 Method of steps

The *Method of steps* can be used as a tool for simple delay differential equations to obtain a solution, given some initial data. The method of steps is best illustrated by looking at an example.

Example 8.1. (Method of steps) Consider the delay problem

$$x' = -x(t-1), \ t > 0, \tag{8.2.1}$$

$$x(s) = \varphi(s) = 10, \ \ -1 \le s \le 0.$$

We will try to piece together the solution on [0, 3].

Step 1. In this step, we find the solution on $0 \le t \le 1$. For $0 \le t \le 1$, we have $-1 \le t - 1 \le 0$, and hence $x(t-1) = 10$. Thus from (8.2.1) we obtain

$$\frac{dx}{dt} = -10,$$

which has the solution

$$x(t) = x(0) + \int_0^t (-10)du = 10 - 10t.$$

Step 2. Now we find the solution on $1 \le t \le 2$. For $1 \le t \le 2$, we have $0 \le t - 1 \le 1$, and hence $x(t-1) = 10 - 10(t-1)$, where we have made use of the solution from Step 1. Thus from (8.2.1) we obtain

$$\frac{dx}{dt} = -10 + 10(t-1),$$

Copyright Elsevier 2022

which has the solution

$$\begin{aligned} x(t) &= x(1) + \int_1^t [-10 + 10(u-1)]du \\ &= 0 - 10u + 5(u-1)^2\Big|_1^t \\ &= -10(t-1) + 5(t-1)^2, \end{aligned}$$

where we have used $x(1) = 0$ from the solution in Step 1.

Step 3. Now we find the solution on $2 \le t \le 3$. For $2 \le t \le 3$, we have $1 \le t-1 \le 2$, and hence $x(t-1) = -10(t-2) + 5(t-2)^2$, where we utilized the solution from Step 2. Thus from (8.2.1) we obtain

$$\frac{dx}{dt} = 10(t-2) - 5(t-2)^2,$$

which has the solution

$$\begin{aligned} x(t) &= x(2) + \int_1^t [10(u-2) - 5(u-2)^2]du \\ &= -5 + 5(t-2)^2 - \frac{5}{3}(t-2)^3, \end{aligned}$$

where we have used $x(2) = -5$ from the solution in Step 2.

In Example 8.1

$$\lim_{t\to 0^-} x'(t) = \lim_{t\to 0^-} \varphi'(t) = 10,$$

and

$$\lim_{t\to 0^+} x'(t) = \lim_{t\to 0^+} (-10t + 10)' = -10.$$

Therefore the solution is not differentiable at the initial time $t_0 = 0$.

Now we consider the basic delay differential equation

$$x' = f(t,\ x(t-\tau)), \quad t \ge 0, \quad x(s) = \varphi(s), \quad -\tau \le s \le 0. \tag{8.2.2}$$

If f and φ are continuous on $\mathbb{R}^2$ and $\mathbb{R}$, respectively, then a unique solution defined by

$$x(t) = \varphi(0) + \int_0^t f(s, \varphi(s-\tau))ds \tag{8.2.3}$$

exists for $0 \le t \le \tau$. We may argue using the method of steps to show that a unique solution exists for all $t \ge 0$, which is valid regardless of how small the delay τ is.

Copyright Elsevier 2022

Note that if $\tau = 0$, then our delay problem becomes an ordinary differential equation. Consider the delay problem

$$x' = x^2(t-\tau),\ t > 0,\ \ x(s) = 1,\ \ -\tau \le s \le 0. \tag{8.2.4}$$

Using the method of steps, we may find a unique solution. However, if we set $\tau = 0$ in (8.2.4) with $x(0) = 1$, then the solution of $x' = x^2(t)$, $t > 0$, exists only for $t < 1$. This example should cement that the existence of solutions in finite delay differential equations is much easier to obtain, unlike ordinary differential equations.

Example 8.2. Consider the predator–prey model with carrying capacity

$$x' = ax - dx^2 - bxy, \quad y' = -cy + kxy,$$

where $x(t)$ and $y(t)$ are the numbers of preys and predators at time t, respectively, with positive constants a, b, c, d, and k. The term kxy represents the predator's utilization of the prey it captures. Hence there is certainly a delay, say $r > 0$. As a consequence, we have the predator–prey delay system

$$x' = ax - dx^2 - bxy, \quad y' = -cy + kx(t-r)y(t-r).$$

Suppose we are given an initial continuous function $(\phi_1(t), \phi_2(t))$ with $x(s) = \phi_1(s)$, $y(s) = \phi_2(s)$, $-r \le s \le 0$. Then by integrating the linear equation

$$y' = -cy + k\phi_1(t-r)\phi_2(t-r),\ 0 \le t \le r,$$

we arrive at the explicit solution of y given by $y(t) := \zeta(t)$. Substituting y back into the equation with x' gives the homogeneous Bernoulli differential equation

$$x' = ax - dx^2 - bx\zeta(t),\ \ x(0) = \phi_1(0), \tag{8.2.5}$$

which can be easily solved using techniques from basic differential equations. To see this, we let $c(t) = a - b\zeta(t)$ and $v = x^{-1}$. Then we have the resulting differential equation in v,

$$v'(t) + c(t)v = b.$$

Multiplying by the integrating factor, integrating, and simplifying, we arrive at the solution

$$x(t) = \frac{\phi_1(0)}{e^{-\int_0^t c(s)ds} + b\phi_1(0)\int_0^t e^{-\int_u^t c(s)ds}du},$$

where we have used $v = x^{-1}$.

Copyright Elsevier 2022

8.3 Existence and uniqueness

We examine the existence and uniqueness of systems with constant delays since they are involved in many applications. For simplicity of notation, we assume that $t_0 = 0$. This should not cause any difficulties or take away from the meaning of the problem.

Let x be an $n \times 1$ vector-valued function, let D be an open set in $\mathbb{R}^n$, and let f be defined on $[0, \infty) \times D^m$. Define an initial function $\varphi : [-\tau, 0] \to \mathbb{R}^m$, where $\tau = \max\{\tau_j,\ 1 \le j \le m\}$. Let $r = \min\{\tau_j,\ 1 \le j \le m\} > 0$ and consider the system with multiple constant delays

$$x' = f(t, x(t-\tau_1), \dots, x(t-\tau_m)), \quad 0 \le t \le t_f, \tag{8.3.1}$$

$$x(s) = \varphi(s), \quad -\tau \le s \le 0. \tag{8.3.2}$$

We may rename the delays so that they are listed in an increasing order so that $\tau = \tau_m$ and $r = \tau_1$:

$$0 \le \tau_1 < \tau_2 < \cdots < \tau_m.$$

Definition 8.3.1. We say that $x : [t_0 - \tau, t_\beta] \to D$ is a solution of (8.3.1)–(8.3.2), where $0 < t_\beta \le t_f$, if it is continuous and satisfies (8.3.1) for $0 \le t < t_\beta$, and $x(s) = \varphi(s)$, $-\tau \le s \le 0$. The solution of (8.3.1)–(8.3.2) is said to be unique if every two solutions agree with each other as far as both are defined.

Theorem 8.3.1. *Let f be continuous on $[0, t_f) \times D^m$, and let $\varphi : [-\tau, 0] \to D$ be continuous on $[-\tau, 0]$. Then system (8.3.1)–(8.3.2) has a unique solution x on $[-\tau, \beta_1)$, where $0 < \beta_1 \le t_f$. Moreover, if $\beta_1 < t_f$, then $x(t)$ approaches the boundary of D as $t \to \beta_1$.*

Proof. Let $t \in [0, r]$. Then every solution resides over the domain of the initial function, that is,

$$x' = f(t, \varphi(t-\tau_1), \dots, \varphi(t-\tau_m))$$

with $x(0) = \varphi(0)$. An integration from 0 to t gives

$$x(t) = \varphi(0) + \int_0^t f(u, \varphi(u-\tau_1), \dots, \varphi(u-\tau_m))du,$$

which uniquely defines $x(t)$ for $0 \le t \le r$, provided that $r < t_f$ and $x(t)$ remains in D. Now that we know $x(t)$ on $[-\tau, r]$, we may continue in this fashion on $[r, 2r]$ as long as $2r < t_f$ and $x(t)$ remains in D. We continue with this method of steps until we reach t_f or until $x(t)$ reaches the boundary of D. This completes the proof. ☐

Remark 8.1. Suppose at least one of the $\tau_j = 0$, $j = 1, 2, \dots, m$. To be specific, suppose only $\tau_1 = 0$ and the rest of the delays are distinct and greater than zero. Then

Copyright Elsevier 2022

system (8.3.1) will include a differential equation. In this case proving the existence and uniqueness requires a Lipschitz condition on f of the form

$$|f(t, y_{(1)}, y_{(2)}, \dots, y_{(m)}) - f(t, z_{(1)}, z_{(2)}, \dots, z_{(m)})| \le K|y_{(1)} - z_{(1)}| \qquad (8.3.3)$$

for $y_{(j)}, z_{(j)} \in \mathbb{R}^n$ and positive constant K.

Corollary 8.1. *(Uniqueness) In addition to the hypotheses of Theorem 8.3.1, assume* (8.3.3). *Then* (8.3.1)–(8.3.2) *has at most one solution on any interval* $[-\tau, \beta_1)$*, where* $0 < \beta_1 \le t_f$.

Proof. The case $r > 0$ is already covered by Theorem 8.3.1, so we let $r = 0$. Then for $t \in [0, \tau_2]$,

$$x' = f(t, x(t), \varphi(t - \tau_2), \dots, \varphi(t - \tau_m))$$

with $x(0) = \varphi(0)$. Then by Theorem 2.2.1, it has at most one solution. We may repeat the above process for $t \in [\tau_2, 2\tau_2]$, for $\tau_2 < t_f$. We keep repeating the process until we reach t_f. This completes the proof. ☐

Recall our remark in Chapter 3 that a multivariable function f satisfies a Lipschitz condition on some region if all its first partial derivatives are continuous on that region. We have the following example.

Example 8.3. Consider the sun flower model

$$u''(t) + bu'(t) + c \sin u(t - r) = 0, \; t \ge 0,$$

where b, c, and r are positive constants. Using the transformation $x_1 = u$, $x_2 = u'$, we arrive at the system

$$x_1'(t) = x_2,$$

$$x_2'(t) = -c \; \sin x_1(t - r) - bx_2.$$

Therefore

$$f(t, y_{(1)}, y_{(2)}) = \begin{pmatrix} y_{(1)2} \\ -c \sin y_{(2)1} - by_{(1)2} \end{pmatrix}.$$

Clearly, f is continuous, and so are the partial derivatives

$$\frac{\partial f_1}{\partial y_{(1)1}} = 0, \qquad \frac{\partial f_1}{\partial y_{(1)2}} = 1, \qquad \frac{\partial f_2}{\partial y_{(1)2}} = -b.$$

Thus by Corollary 8.1, given any continuous function $\varphi : [-r, 0] \to \mathbb{R}^2$, the delay system has at most one solution on $[-r, \beta_1)$ for any $\beta_1 > 0$.

Copyright Elsevier 2022

8.4 Stability using Lyapunov functions

In this section, we consider general forms of delay differential equations that fall into the category of *functional delay differential equations*. A functional delay differential equation is a delay differential equation where the unknowns are functions. We will adopt the following notation. For any $r \geq 0$, any continuous function $x(u)$ defined on $-r \leq u \leq A$, $A > 0$, and any fixed t, $0 \leq t \leq A$, by x_t we denote the function $x_t(s) = x(t+s)$, $-r \leq s \leq 0$, that is, $x : [a,\ b] \to \mathbb{R}^n$ is continuous and is the segment of the function $x(s)$ defined by letting s range in the interval $t - r \leq s \leq t$. We consider the functional delay differential equation

$$x'(t) = F(t, x_t),\ t \geq t_0. \tag{8.4.1}$$

We assume that F is continuous in both arguments and that $F : \mathbb{R} \times C \to \mathbb{R}^n$, where C is the set of continuous functions $\phi : [-\alpha, 0] \to \mathbb{R}^n$, $\alpha > 0$. If $t_0 = -\infty$, then $t \geq t_0$ means that $t > t_0$. Let

$$C(t) = \{\phi : [t-\alpha, t] \to \mathbb{R}^n\}.$$

It is to be understood that $C(t)$ is C for $t = 0$. Also, ϕ_t denotes $\phi \in C(t)$, and $||\phi_t|| = \max\limits_{t-\alpha \leq s \leq t} |\phi(t)|$, where $|\cdot|$ is a convenient norm on $\mathbb{R}^n$. A solution is denoted by $x(t_0, \phi_{t_0})$, and its value by $x(t, t_0, \phi_{t_0})$ or, if there is no confusion, by $x(t_0, \phi)$ and $x(t, t_0, \phi)$.

Definition 8.4.1. Let $x(t) = 0$ be a solution of (8.4.1).

(a) The zero solution of (8.4.1) is stable if for all $\varepsilon > 0$ and $t_1 \geq t_0$, there exists $\delta > 0$ such that $[\phi \in C(t_1),\ \|\phi\| < \delta, t \geq t_1]$ imply that $|x(t, t_1, \phi)| < \varepsilon$.

(b) The zero solution of (8.4.1) is uniformly stable if it is stable and if δ is independent of $t_1 \geq t_0$.

(c) The zero solution of (8.4.1) is asymptotically stable if it is stable and if for each $t_1 \geq t_0$, there is $\eta > 0$ such that $[\phi \in C(t_1),\ \|\phi\| < \eta]$ imply that $|x(t, t_1, \phi)| \to 0$ as $t \to \infty$. Note that if this is true for every $\eta > 0$, then $x = 0$ is asymptotically stable in the large or globally asymptotically stable.

(d) The zero solution of (8.4.1) is uniformly asymptotically stable if it is uniformly stable and if there is $\eta > 0$ such that for each $\gamma > 0$, there exists $S > 0$ such that $[t_1 \geq t_0, \phi \in C(t_1),\ \|\phi\| < \eta, t \geq t_1 + S]$ imply that $|x(t, t_1, \phi)| < \gamma$. We also note that if this is true for every $\eta > 0$, then $x = 0$ is uniformly asymptotically stable in the large.

Let $W_i : [0, \infty) \to [0, \infty)$ be continuous with $W_i(0) = 0$, $W_i(r)$ strictly increasing, and $W_i(r) \to \infty$ as $r \to \infty$, $i = 1, 2, 3$.

Consider the totally nonlinear differential equation with bounded delay

$$x'(t) = -ax^3(t) + bx^3(t-r),\ t \geq t_0 \geq 0,$$

where a, b, and r are positive constants. Consider the Lyapunov-type functional

$$V(x_t) = |x(t)| + b\int_{t-r}^{t} |x^3(s)|ds.$$

Let $a \geq b$. Then along the solutions we have

$$\begin{aligned} V'(x_t) &= \frac{x}{|x|}x' - b|x^3(t-r)| + b|x^3(t)| \\ &= \frac{x}{|x|}\big(-ax^3(t) + bx^3(t-r)\big) - b|x^3(t-r)| + b|x^3(t)| \\ &\leq -a|x^3(t)| + b|x^3(t-r)| - b|x^3(t-r)| + b|x^3(t)| \\ &= [-a+b]|x^3| \leq 0. \end{aligned} \tag{8.4.2}$$

Let $t_1 \in \mathbb{R}$, $\varphi \in C(t_1)$, and $x(t) = x(t, t_1, \varphi)$. Using the fact that $|x(t)| \leq V(x_t)$ and integrating (8.4.2) from $t_1 - r$ to t_1 yield

$$\begin{aligned} |x(t)| \leq V(x_t) &\leq V(\varphi_{t_1}) \\ &= |\varphi(t_1)|^3 + b\int_{t_1-r}^{t_1} |\varphi^3(s)|ds \\ &\leq \big(1+br\big)||\varphi_{t_1}||^3. \end{aligned} \tag{8.4.3}$$

Suppose $a > b$, let $\varepsilon > 0$, and choose $\delta = \Big(\frac{\varepsilon}{1+br}\Big)^{1/3}$. Then for $||\varphi_{t_1}|| < \delta$, from (8.4.3) we have

$$|x(t)| \leq \big(1+br\big)\Big[\Big(\frac{\varepsilon}{1+br}\Big)^{1/3}\Big]^3 = \varepsilon,$$

and the zero solution is uniformly stable. Note that stability is independent of the size of the delay r.

Integrate (8.4.2) for 0 to t and obtain $V(x_t) - V(\varphi_0) \leq -\int_0^t |x(s)|^3 ds$, which implies that

$$\int_0^t |x(s)|^3 ds \leq V(\varphi_0) - V(x_t) \leq V(\varphi_0) < \infty$$

for all $t \geq 0$. Hence $x^3(t) \in L^1[0, \infty)$.

Next, we prove parallel theorems to Theorems 7.1.8–7.1.11 concerning system (8.4.1).

Theorem 8.4.1. *Let $D > 0$. Suppose $V(t, \psi_t)$ is a scalar functional continuous in ψ and locally Lipschitz in ψ_t when $t \geq t_0$ and $\psi_t \in C(t)$ with $||\psi_t|| < D$. Suppose also that $V(t, 0) = 0$ and*

$$W_1(|\psi(t)|) \leq V(t, \psi_t). \tag{8.4.4}$$

Copyright Elsevier 2022

(a) *If*

$$V'(t,\psi_t) \le 0 \text{ for } t_0 \le t < \infty \text{ and } ||\psi_t|| \le D, \tag{8.4.5}$$

then the zero solution of (8.4.1) *is stable.*

(b) *If in addition to (a),*

$$V(t,\psi_t) \le W_2(||\psi_t||), \tag{8.4.6}$$

then the zero solution of (8.4.1) *is uniformly stable.*

(c) *If there is* $M > 0$ *such that* $|F(t,\psi_t)| \le M$ *for* $t_0 \le t < \infty$ *and* $||\psi_t|| \le D$, *and if*

$$V'(t,\psi_t) \le -W_2(|\psi(t)|), \tag{8.4.7}$$

then the zero solution of (8.4.1) *is asymptotically stable.*

Proof. Let $\varepsilon > 0$ be such that $\varepsilon < D$. Let $t_1 \ge t_0$. Since V is continuous and $V(t,0) = 0$, there exists $\delta > 0$ such that $\phi \in C(t_1)$ with $||\phi_{t_1}|| < \delta$ implies that $V(t_1,\phi_{t_1}) < W_1(\varepsilon)$. By condition (8.4.5) we have

$$\begin{aligned} W_1(|x(t,t_1,\phi_{t_1})|) &\le V(t,x(t,t_1,\phi_{t_1})) \le V(t_1,\phi_{t_1}) \\ &\le W_1(\varepsilon), \end{aligned}$$

from which it follows that

$$|x(t,t_1,\phi_{t_1})| \le W_1^{-1}\big(W_1(\varepsilon)\big) = \varepsilon.$$

This concludes the proof of (a).

As for the proof of (b), we let $\varepsilon > 0$ be such that $\varepsilon < D$. We find $\delta > 0$ with $W_2(\delta) < W_1(\varepsilon)$. Let $t_1 \ge t_0$ and $\phi_{t_1} \in C(t_1)$ with $||\phi_{t_1}|| < \delta$. Then

$$\begin{aligned} W_1(|x(t,t_1,\phi_{t_1})|) &\le V(t,x_t(t_1,\phi_{t_1})) \le V(t_1,\phi_{t_1}) \\ &\le W_2(\delta) < W_1(\varepsilon), \end{aligned}$$

from which it follows that

$$|x(t,t_1,\phi_{t_1})| \le W_1^{-1}\big(W_1(\varepsilon)\big) = \varepsilon.$$

This concludes the proof of (b).

To prove (c), let $t_1 \ge t_0$, and let $0 < \varepsilon < D$. Find δ as in part (b) and take $\eta = \delta$. Let $\phi_{t_1} \in C(t_1)$ with $||\phi_{t_1}|| < \delta$. For simplicity, we write $x(t) = x(t,t_1,\phi_{t_1})$. We will establish the proof by contradiction. Assume that $x(t) \nrightarrow 0$ as $t \to \infty$. Then there are $\varepsilon_1 > 0$ and a sequence $\{t_n\} \to \infty$ with $|x(t_n)| \ge \varepsilon_1$. Since $|F(t,\psi_t)| \le M$ for $t_0 \le t < \infty$ and $||\psi_t|| \le D$, there are $T > 0$ and $\varepsilon_2 < \varepsilon_1$ with $|x(t_n)| \ge \varepsilon_2$ for $t_n \le t \le t_n + T$.

Copyright Elsevier 2022

From this and condition (8.4.7) it follows that

$$
\begin{aligned}
0 \le V(t, x_t) \le V(t_1, \phi_{t_1}) &- \int_{t_1}^{t} W_2(|x(s)|) \\
\le V(t_1, \phi_{t_1}) &- \sum_{i=2}^{n} \int_{t_i}^{t_i+T} W_2(|x(s)|) \\
\le V(t_1, \phi_{t_1}) &- \sum_{i=2}^{n} \int_{t_i}^{t_i+T} W_2(\varepsilon_2) \\
= V(t_1, \phi_{t_1}) &- (n-1)T W_2(\varepsilon_2) \to -\infty \text{ as } n \to \infty,
\end{aligned}
$$

a contradiction. This concludes the proof of (c). ☐

Theorem 8.4.2. *Let* $D > 0$. *Suppose* $V(t, \psi_t)$ *is a scalar functional continuous in* ψ *and locally Lipschitz in* ψ_t *when* $t \ge t_0$ *and* $\psi_t \in C(t)$ *with* $||\psi_t|| < D$. *In addition, we assume that if* $x : [t_0 - \alpha, \infty) \to \mathbb{R}^n$ *is bounded, then* $F(t, x_t)$ *is bounded on* $[t_0, \infty)$. *Suppose* V *satisfies* $V(t, 0) = 0$,

$$W_1(|\psi(t)|) \le V(t, \psi_t) \le W_2(||\psi_t||), \tag{8.4.8}$$

and

$$V'(t, \psi_t) \le -W_3(|\psi(t)|). \tag{8.4.9}$$

Then the zero solution of (8.4.1) *is uniformly asymptotically stable.*

Proof. We refer to [15]. ☐

In the next theorem, we use a Lyapunov function and obtain boundedness results concerning non-homogeneous delay differential equations.

Theorem 8.4.3. *Let* $h > 0$ *and consider the finite delay differential equation*

$$x'(t) = a(t)x(t) + b(t)x(t-h) + g(t), \; t \ge 0, \tag{8.4.10}$$

with $x(t_0) = \varphi(t_0)$, $-h \le t_0 \le 0$. *Suppose* $a(t)$, $b(t)$, *and* $g(t)$ *are continuous for all* $t \ge 0$.

Assume that

$$2a(t) + 3 + |b(t)| \le 0, \tag{8.4.11}$$

$$|b(t)| - e^{-h} \le 0, \tag{8.4.12}$$

and there exists a positive constant L *such that*

$$|g(t)| \le L, \; t \ge 0.$$

Then all solutions of (8.4.10) *are uniformly bounded. Moreover, if* $g(t) = 0$ *for all* $t \ge 0$, *then the zero solution is exponentially stable.*

Copyright Elsevier 2022

Proof. For $t \geq 0$, let

$$V(t, x_t) = x^2(t) + \int_{t-h}^{t} e^{-(t-s)} x^2(s)\, ds.$$

Then along solutions of (8.4.10) we have

$$\begin{aligned} V'(t,x) &= 2a(t)x^2(t) + 2b(t)x(t)x(t-h) + 2x(t)g(t) + x^2(t) \\ &\quad - e^{-h}x^2(t-h) - \int_{t-h}^{t} e^{-(t-s)} x^2(s)\, ds \\ &\leq (2a(t) + 2 + |b(t)|)x^2(t) + (|b(t)| - e^{-h})x^2(t-h) \\ &\quad - \int_{t-h}^{t} e^{-(t-s)} x^2(s)\, ds + g^2(t). \end{aligned}$$

Using conditions (8.4.11) and (8.4.12), we have

$$\begin{aligned} V(t,x_t) + V'(t,x_t) &\leq (2a(t) + 3 + |b(t)|)x^2(t) + (|b(t)| - e^{-h})x^2(t-h) \\ &\quad - \int_{t-h}^{t} e^{-(t-s)} x^2(s)\, ds + \int_{t-h}^{t} e^{-(t-s)} x^2(s)\, ds + g^2(t) \\ &\leq g^2(t) \leq L^2. \end{aligned}$$

So we have

$$V'(t, x_t) \leq -V(t, x_t) + L^2.$$

It follows from the variation of parameters formula that

$$\begin{aligned} |x| &\leq \left[V(t_0, \varphi)e^{-(t-t_0)} + L^2\right]^{1/2} \\ &\leq \left[\left(1 + \int_{t_0-h}^{t_0} e^{-(t_0-s)}\, ds\right)||\varphi||^2\, e^{-(t-t_0)} + L^2\right]^{1/2} \\ &\leq \left[\left(2 - e^{-h}\right)||\varphi||^2\, e^{-(t-t_0)} + L^2\right]^{1/2}. \end{aligned}$$

This gives boundedness. Now if $g(t) = 0$ for all $t \geq 0$, then $L = 0$, and hence the above inequality gives the exponential stability. ☐

We end this section by noting that despite the results of Exercises 8.8 and 8.9, researchers are still trying to substitute delay terms with terms that are independent of delays and arrive at ordinary differential equations that can be explicitly solved. This could be a good prospect for research using numerical analysis.

Copyright Elsevier 2022

8.5 Stability using fixed point theory

Lyapunov functions and functionals have been successfully used to obtain boundedness, stability, and the existence of periodic solutions of differential equations, differential equations with functional delays, and functional differential equations. In the study of differential equations with functional delays by using Lyapunov functionals, many difficulties arise if the delay is unbounded or if the differential equation in question has unbounded terms. This section is mainly concerned with the asymptotic stability of the zero solution of the scalar neutral differential equation

$$x'(t) = -a(t)x(t) + c(t)x'(t-g(t)) + q\big(t, x(t), x(t-g(t))\big), \tag{8.5.1}$$

where $a(t)$, $c(t)$, $g(t)$, and q are continuous in their respective arguments. What makes Eq. (8.5.1) interesting to study is the fact that it cannot be put in the form of

$$\frac{d}{dt}[x(t) + c(t)x(t-g(t))] = -a(t)x(t) + q\big(t, x(t), x(t-g(t))\big),$$

and hence a direct integration cannot be performed to arrive at the desired mapping. We could not construct a suitable Lyapunov functional that yielded any meaningful results about the asymptotic stability of the zero solution. Hence the construction of such a Lyapunov functional for Eq. (8.5.1) remains open. Moreover, in this study, we concentrate on the stability of the zero solution of nonlinear neutral differential equations with bounded and unbounded delays. To achieve our goal, we make use of the contraction mapping principle. To justify the need of using fixed point theory when studying stability, we consider the time-varying delay differential equation

$$x'(t) = -a(t)x(t) + b(t)x(t-g(t)), \tag{8.5.2}$$

where a and b are bounded continuous functions, and g is continuously differentiable and nonnegative.

Theorem 8.5.1. *Suppose*

$$g'(t) \text{ is bounded}, \; 1 - g'(t) > 0, \tag{8.5.3}$$

$$-2a(t) + 1 \le -(1 - g'(t)), \tag{8.5.4}$$

and

$$|b(t)| \le \alpha(1 - g'(t)) \text{ for some } \alpha \in (0,1). \tag{8.5.5}$$

Then the zero solution of (8.5.2) *is uniformly asymptotically stable.*

Proof. Define the Lyapunov functional

$$V(t) = x^2(t) + \int_{t-g(t)}^{t} x^2(s)\, ds.$$

Copyright Elsevier 2022

Then along solutions of (8.5.2) we have

$$\begin{aligned}
V'(t) &= 2x(t)\Big(-a(t)x(t) + b(t)x(t-g(t))\Big) + x^2(t) - (1-g'(t))x^2(t-g(t)) \\
&\le -2a(t)x^2(t) + |b(t)|x^2(t) + |b(t)|x^2(t-g(t)) \\
&+ x^2(t) - (1-g'(t))x^2(t-g(t)) \\
&= \Big(-2a(t) + |b(t)| + 1\Big)x^2(t) + \Big(|b(t)| - (1-g'(t))\Big)x^2(t-g(t)) \\
&\le (\alpha-1)(1-g'(t))\Big(x^2(t) + x^2(t-g(t))\Big) \\
&\le (\alpha-1)(1-g'(t))x^2(t).
\end{aligned}$$

The result follows from Theorem 8.4.2. □

We remark that (8.5.4) and (8.5.5) imply that $|b(t)| \le \alpha(2a(t)-1)$. Thus we see that $|b(t)|$ must be bounded by $a(t)$. In addition, $a(t)$ must satisfy $a(t) \ge 1/2$.

8.5.1 Neutral differential equations

Conditions (8.5.3) and (8.5.4) are severe since a and b must be bounded and both a and b must satisfy an upper bound in terms of $1-g'$. To relax the restrictions, we resort to the use of fixed point theory, namely, the contraction mapping principle. To better illustrate our procedure, we first consider the scalar linear neutral differential equation (neutral since there is a delay in the derivative) with unbounded delay

$$x'(t) = -a(t)x(t) + b(t)x(t-g(t)) + c(t)x'(t-g(t)), \tag{8.5.6}$$

where $a(t)$ and $b(t)$ are continuous, $c(t)$ is continuously differentiable, and $g(t) > 0$ for all $t \in \mathbb{R}$ and is twice continuously differentiable. We note that Eq. (8.5.6) is more complicated than that we considered in Theorem 8.5.1 since the derivative on the right side has a delay. Hence the Lyapunov functional that was used in the proof of Theorem 8.5.1 will not work, and we have to construct a suitable one. However, the author believes that conditions similar to (8.5.3)–(8.5.5) have to be imposed. Using fixed point theory, a suitable mapping has to be formulated. To obtain the desired map, we invert Eq. (8.5.6). During the process of inverting (8.5.6), we have to integrate by parts the term involving $x'(t-g(t))$. We begin by requiring that

$$g'(t) \ne 1, \quad \forall\ t \in \mathbb{R}. \tag{8.5.7}$$

Definition 8.3.1 naturally extends to suit Eq. (8.5.6).

Lemma 8.1. *Suppose* (8.5.7) *holds. Then* $x(t)$ *is a solution of Eq.* (8.5.6) *if and only if*

Copyright Elsevier 2022

$$x(t) = \left(x(0) - \frac{c(0)}{1-g'(0)}x(-g(0))\right)e^{-\int_0^t a(s)ds} + \frac{c(t)}{1-g'(t)}x(t-g(t))$$
$$- \int_0^t (r(u) - b(u))x(u-g(u))e^{-\int_u^t a(s)ds}du, \tag{8.5.8}$$

where

$$r(u) = \frac{\left(c'(u) + c(u)a(u)\right)\left(1-g'(u)\right) + g''(u)c(u)}{(1-g'(u))^2}. \tag{8.5.9}$$

Proof. Multiplying both sides of (8.5.6) by $e^{\int_0^t a(s)ds}$ and then integrating from 0 to t, we obtain

$$\int_0^t \left[x(u)e^{\int_0^u a(s)ds}\right]' du = \int_0^t \left[b(u)x(u-g(u)) + c(u)x'(u-g(u))\right]e^{\int_0^u a(s)ds}du.$$

As a consequence, we arrive at

$$x(t)e^{\int_0^t a(s)ds} - x(0) = \int_0^t \left[b(u)x(u-g(u)) + c(u)x'(u-g(u))\right]e^{\int_0^u a(s)ds}du.$$

Dividing both sides of the above equation by $e^{\int_0^t a(s)ds}$, we obtain

$$x(t) = x(0)e^{-\int_0^t a(s)ds}$$
$$+ \int_0^t \left[b(u)x(u-g(u)) + c(u)x'(u-g(u))\right]e^{-\int_u^t a(s)ds}du. \tag{8.5.10}$$

Rewrite

$$\int_0^t c(u)x'(u-g(u))e^{-\int_u^t a(s)ds}du$$
$$= \int_0^t \frac{c(u)x'(u-g(u))(1-g'(u))}{(1-g'(u))}e^{-\int_u^t a(s)ds}du.$$

Integrating by parts the above integral with

$$U(u) = \frac{c(u)}{1-g'(u)}e^{-\int_u^t a(s)ds}$$

and

$$dV = x'(u-g(u))(1-g'(u))du,$$

we have

$$\int_0^t c(u)x'(u-g(u))e^{-\int_u^t a(s)ds}du = \frac{c(t)}{1-g'(t)}x(t-g(t))$$
$$- \frac{c(0)}{1-g'(0)}x(-g(0))e^{-\int_0^t a(s)ds} - \int_0^t r(u)e^{-\int_u^t a(s)ds}x(u-g(u))du, \tag{8.5.11}$$

Copyright Elsevier 2022

where $r(u)$ is given by (8.5.9). Finally, substituting (8.5.11) into (8.5.10) completes the proof. $\square$

Next, let $\psi(t) : (-\infty, 0] \to \mathbb{R}$ be a continuous bounded initial function. We say that $x(t) := x(t, 0, \psi)$ is a solution of (8.5.6) if $x(t) = \psi(t)$ for $t \le 0$ and satisfies (8.5.6) for $t \ge 0$.

We say that the zero solution of (8.5.6) is stable at t_0 if for each $\varepsilon > 0$, there is $\delta = \delta(\varepsilon) > 0$ such that $\big[\psi : [-\infty, t_0] \to \mathbb{R}$ with $|\psi(t)| < \delta$ on $(-\infty, t_0],\ t \ge t_0\big]$ implies $|x(t, t_0, \psi)| < \varepsilon$.

Let C be the space of all continuous functions from $\mathbb{R} \to \mathbb{R}$ and define the set

$$S = \Big\{\varphi : \mathbb{R} \to \mathbb{R} \,\Big|\, \varphi(t) = \psi(t) \text{ if } t \le 0,\ \varphi(t) \to 0 \text{ as } t \to \infty,\ \varphi \in C, \\ \text{and } \varphi \text{ is bounded}\Big\}.$$

Then $\big(S, ||\cdot||\big)$ is a complete metric space, where $||\cdot||$ is the supremum norm.

For the next theorem, we impose the following conditions:

$$e^{-\int_0^t a(s)ds} \to 0 \text{ as } t \to \infty, \tag{8.5.12}$$

there is $\alpha > 0$ such that

$$\left|\frac{c(t)}{1-g'(t)}\right| + \int_0^t |r(u) - b(u)| e^{-\int_u^t a(s)ds} du \le \alpha < 1, t \ge 0, \tag{8.5.13}$$

and

$$t - g(t) \to \infty \text{ as } t \to \infty. \tag{8.5.14}$$

Theorem 8.5.2. *If* (8.5.7) *and* (8.5.12)–(8.5.14) *hold, then every solution* $x(t, 0, \psi)$ *of* (8.5.6) *with small continuous initial function* $\psi(t)$ *is bounded and goes to zero as* $t \to \infty$. *Moreover, the zero solution is stable at* $t_0 = 0$.

Proof. Define the mapping $P : S \to S$ by

$$\big(P\varphi\big)(t) = \psi(t) \text{ if } t \le 0$$

and

$$\big(P\varphi\big)(t) = \Big(\psi(0) - \frac{c(0)}{1-g'(0)}\psi(-g(0))\Big)e^{-\int_0^t a(s)ds} + \frac{c(t)}{1-g'(t)}\varphi(t-g(t)) \\ - \int_0^t \Big[r(u) - b(u)\Big]\varphi(u - g(u))e^{-\int_u^t a(s)ds} du,\ t \ge 0.$$

It is clear that for $\varphi \in S$, $P\varphi$ is continuous. Let $\varphi \in S$ with $||\varphi|| \le K$ for some positive constant K. Let $\psi(t)$ be a small continuous initial function with $|\psi| < \delta$, $\delta > 0$. Then

Copyright Elsevier 2022

using (8.5.13) in the definition of $(P\varphi)(t)$, we have

$$\begin{aligned}
||(P\varphi)(t)|| &\le |(1-\frac{c(0)}{1-g'(0)})|K+|\frac{c(t)}{1-g'(t)}|K \\
&\quad +\int_0^t |r(u)-b(u)|e^{-\int_u^t a(s)ds}du\,K \\
&\le |(1-\frac{c(0)}{1-g'(0)})|\delta+\alpha K, \qquad (8.5.15)
\end{aligned}$$

which implies that $||\big(P\varphi\big)(t)|| \le K$ for the right δ. Thus (8.5.15) implies that $(P\varphi)(t)$ is bounded. Next, we show that $\big(P\varphi\big)(t) \to 0$ as $t \to \infty$. The first term on the right side of $\big(P\varphi\big)(t)$ tends to zero by condition (8.5.12). Also, the second term on the right side tends to zero because of (8.5.14) and the fact that $\varphi \in S$. It remains to show that the integral term goes to zero as $t \to \infty$.

Let $\varepsilon > 0$, and let $\varphi \in S$ with $||\varphi|| \le K$, $K > 0$. Then there exists $t_1 > 0$ such that $|\varphi(t-g(t))| < \varepsilon$ for $t > t_1$. Due to condition (8.5.12), there exists $t_2 > t_1$ such that $e^{-\int_{t_1}^t a(s)ds} < \frac{\varepsilon}{\alpha K}$ for $t > t_2$. Thus for $t > t_2$, we have

$$\begin{aligned}
&\Big|\int_0^t (r(u)-b(u))\varphi(u-g(u))e^{-\int_u^t a(s)ds}du\Big| \\
&\le K\int_0^{t_1} |r(u)-b(u)|e^{-\int_u^t a(s)ds}du+\varepsilon\int_{t_1}^t |r(u)-b(u)|e^{-\int_u^t a(s)ds}du \\
&\le Ke^{-\int_{t_1}^t a(s)ds}\int_0^{t_1} |r(u)-b(u)|e^{-\int_u^{t_1} a(s)ds}du+\alpha\varepsilon \\
&\le \alpha Ke^{-\int_{t_1}^t a(s)ds}+\alpha\varepsilon \\
&\le \varepsilon+\alpha\varepsilon.
\end{aligned}$$

Hence $\big(P\varphi\big)(t) \to 0$ as $t \to \infty$. It remains to show that $\big(P\varphi\big)(t)$ is a contraction under the supremum norm. Let $\zeta, \eta \in S$. Then

$$\begin{aligned}
\Big|(P\zeta)(t)-(P\eta)(t)\Big| &\le \Big\{|\frac{c(t)}{1-g'(t)}|+\int_0^t |r(u)-b(u)|e^{-\int_u^t a(s)ds}du\Big\}||\zeta-\eta|| \\
&\le \alpha||\zeta-\eta||.
\end{aligned}$$

Thus by the contraction mapping principle, P has a unique fixed point in S, which solves (8.5.6), is bounded, and tends to zero as t tends to infinity. The stability of the zero solution at $t_0 = 0$ follows from the above work by simply replacing K by ε. This completes the proof. □

Example 8.4. Consider the linear neutral differential equation

$$x'(t) = -2x(t) + c_0\,x'(t-(\frac{t}{2})), \qquad (8.5.16)$$

Copyright Elsevier 2022

where c_0 is a constant. Then $r(u) = -4c_0$, and condition (8.5.13) is satisfied for $|c_0| \leq \frac{\alpha}{4}$, $\alpha \in (0,1)$. Let $\psi(t)$ be a given continuous initial function with $|\psi(t)| \leq \delta$. Let

$$S = \Big\{\varphi : \mathbb{R} \to \mathbb{R} \,\Big|\, \varphi(t) = \psi(t) \text{ if } t \leq 0,\ \varphi(t) \to 0 \text{ as } t \to \infty,\ \varphi \in C, \\ \text{and } \varphi \text{ is bounded}\Big\}.$$

Define

$$\big(P\varphi\big)(t) = \psi(t) \ \text{ if } \ t \leq 0$$

and

$$\big(P\varphi\big)(t) = \Big((1-2c_0)\psi(0)\Big)e^{-2t} + 2c_0\varphi(\frac{t}{2}) \\ + \int_0^t 4c_0\varphi(\frac{u}{2})e^{-2(t-u)}du,\ t \geq 0.$$

Then, for $\varphi \in S$ with $||\varphi|| \leq K$, where $K \geq \frac{(1-\alpha)}{|1-2c_0|\delta}$, we have $||\big(P\varphi\big)(t)|| \leq K$. It is obvious that conditions (8.5.12) and (8.5.14) are satisfied. To see that P defines a contraction mapping, let $\zeta, \eta \in S$. Then

$$\Big|(P\zeta)(t) - (P\eta)(t)\Big| \leq 2|c_0|\,||\zeta-\eta|| + 2|c_0|(1-e^{-2t})||\zeta-\eta|| \\ \leq 4|c_0|\,||\zeta-\eta|| \leq \alpha||\zeta-\eta||.$$

Hence by Theorem 8.5.2 every solution $x(t,0,\psi)$ of (8.5.16) with small continuous initial function $\psi(t) : (-\infty,\ 0] \to \mathbb{R}$ is in S, is bounded, and goes to zero as $t \to \infty$.

Next, we turn our attention to the nonlinear neutral differential equation with unbounded delay

$$x'(t) = -a(t)x(t) + c(t)x'(t-g(t)) + q\Big(x(t), x(t-g(t))\Big), \tag{8.5.17}$$

where $a(t)$, $c(t)$, and $g(t)$ are defined as before. Here we assume that $q(0,0) = 0$ and q is locally Lipschitz continuous in x and y in the sense that there is $K > 0$ such that if $|x|, |y|, |z|, |w| \leq K$, then

$$|q(x,y) - q(z,w)| \leq L|x-z| + E|y-w| \tag{8.5.18}$$

for some positive constants L and E.

Note that

$$|q(x,y)| = |q(x,y) - q(0,0) + q(0,0)| \\ \leq |q(x,y) - q(0,0)| + |q(0,0)| \\ \leq L|x| + E|y|.$$

Copyright Elsevier 2022

Let

$$S=\Big\{\varphi:\mathbb{R}\to\mathbb{R}\,\Big|\,||\varphi||\le K,\ \varphi(t)=\psi(t)\text{ if }t\le 0,\ \varphi(t)\to 0\text{ as }t\to\infty,\ \varphi\in C\Big\}.$$

Define the map $P:S\to S$ by

$$\big(P\varphi\big)(t)=\psi(t)\quad\text{if }\ t\le 0$$

and

$$\big(P\varphi\big)(t)=\Big(\psi(0)-\frac{c(0)}{1-g'(0)}\psi(-g(0))\Big)e^{-\int_0^t a(s)ds}+\frac{c(t)}{1-g'(t)}\varphi(t-g(t))$$
$$+\int_0^t\Big[-r(u)\varphi(u-g(u))+q(\varphi(u),\varphi(u-g(u)))\Big]e^{-\int_u^t a(s)ds}du,\ t\ge 0.$$

It is clear that $P\varphi$ is continuous for $\varphi\in S$. If P has a fixed point, say φ, then φ is a solution of (8.5.17). For P to be a contraction, we assume that there is $\alpha>0$ such that

$$\Big|\frac{c(t)}{1-g'(t)}\Big|+\int_0^t(|r(u)|+L+E)e^{-\int_u^t a(s)ds}du\le\alpha<1,t\ge 0. \tag{8.5.19}$$

Theorem 8.5.3. *If* (8.5.7), (8.5.12), (8.5.14), *and* (8.5.19) *hold, then every solution* $x(t,0,\psi)$ *of* (8.5.17) *with small continuous initial function* $\psi(t):(-\infty,0]\to\mathbb{R}$ *goes to zero as* $t\to\infty$. *Moreover, the zero solution is stable at* $t_0=0$.

Proof. Let $\varphi\in S$, and let t_1 and t_2 be as in the proof of Theorem 8.5.2. Then for $t>t_2$,

$$\begin{aligned}&\Big|\int_0^t q(\varphi(u),\varphi(u-g(u)))e^{-\int_u^t a(s)ds}du\Big|\\&\le K(L+E)\int_0^{t_1}e^{-\int_u^t a(s)ds}du+\varepsilon(L+E)\int_{t_1}^t e^{-\int_u^t a(s)ds}du\\&\le K(L+E)e^{-\int_{t_1}^t a(s)ds}\int_0^{t_1}e^{-\int_u^{t_1}a(s)ds}du+\varepsilon(L+E)\alpha\\&\le\alpha Ke^{-\int_{t_1}^t a(s)ds}+\varepsilon(L+E)\alpha\\&\le\varepsilon+\varepsilon(L+E)\alpha.\end{aligned}$$

This, along with the proof of Theorem 8.5.2, shows that $\big(P\varphi\big)(t)\to 0$ as $t\to\infty$. Let $\psi(t)$ be a small continuous initial function with $|\psi|<\delta$, $\delta>0$. Then by using

Copyright Elsevier 2022

(8.5.19) we arrive at

$$\begin{aligned}
||\big(P\varphi\big)(t)|| &\leq |(1-\frac{c(0)}{1-g'(0)})|\delta + |\frac{c(t)}{1-g'(t)}|K \\
&\quad + \int_0^t (|r(u)|+L+E)e^{-\int_u^t a(s)ds}du K \\
&\leq |(1-\frac{c(0)}{1-g'(0)})|\delta + \alpha K,
\end{aligned} \tag{8.5.20}$$

which implies that $||\big(P\varphi\big)(t)|| \leq K$ with the right choice of δ and α. It remains to show that $\big(P\varphi\big)(t)$ is a contraction. Let $\zeta, \eta \in S$. Then

$$\begin{aligned}
&\Big|(P\zeta)(t) - (P\eta)(t)\Big| \\
&\leq \Big\{|\frac{c(t)}{1-g'(t)}|\,||\zeta-\eta|| + \int_0^t \big(|r(u)||\zeta(u-g(u)) - \eta(u-g(u))|e^{-\int_u^t a(s)ds}du \\
&+ \int_0^t |q(\zeta(u),\zeta(u-g(u))) - q(\eta(u),\eta(u-g(u)))|e^{-\int_u^t a(s)ds}du\Big\} \\
&\leq \Big\{|\frac{c(t)}{1-g'(t)}| + \int_0^t (|r(u)|+L+E)e^{-\int_u^t a(s)ds}du\Big\}||\zeta-\eta|| \\
&\leq \alpha||\zeta-\eta||.
\end{aligned}$$

Thus by the contraction mapping principle, P has a unique fixed point in S, which solves (8.5.17) and tends to zero as t tends to infinity. This completes the proof. ☐

8.5.2 Neutral Volterra integro-differential equations

Now we turn our attention to the scalar neutral Volterra integro-differential equation

$$x'(t) = -a(t)x(t) + c(t)x'(t-g(t)) + \int_{t-g(t)}^t k(t,s)h(x(s))ds, \tag{8.5.21}$$

where $0 \leq g(t) \leq g_0$ for some constant g_0. Here we assume that $g, a, c, h : \mathbb{R} \to \mathbb{R}$ and $k : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ are continuous. For the next theorem, we make the following assumptions:

$$\Big|\frac{c(t)}{1-g'(t)}\Big| + \int_0^t \Big[|r(s)| + \int_{s-g(s)}^s |k(s,u)|du\Big]e^{-\int_s^t a(u)du}ds \leq \alpha < 1, t \geq 0; \tag{8.5.22}$$

for each $\varepsilon > 0$, there exist $t_1 > 0$ and $T > 0$ such that for $t_2 \geq t_1$ and $t \geq t_2 + T$, we have

$$e^{-\int_{t_2}^t a(s)ds} < \varepsilon \text{ and } e^{-\int_0^t a(s)ds} \to 0 \text{ as } t \to \infty; \tag{8.5.23}$$

Copyright Elsevier 2022

and there is $L > 0$ such that $|x|, |y| \le L$ imply that

$$|h(x) - h(y)| \le |x - y| \text{ and } h(0) = 0. \tag{8.5.24}$$

Theorem 8.5.4. *If* (8.5.22)–(8.5.24) *hold, then the zero solution of* (8.5.21) *is asymptotically stable at* $t_0 = 0$.

Proof. Let $\psi : [-g_0, 0] \to \mathbb{R}$ be a bounded initial function with $|\psi| < \delta$ for some positive constant δ. Define

$$S = \Big\{\varphi : [-g_0, \infty) \to \mathbb{R} \,\Big|\, \varphi(t) = \psi(t) \text{ if } -g_0 \le t \le 0,\ ||\varphi|| \le L,$$
$$\varphi \in C,\ \varphi(t) \to 0 \text{ as } t \to \infty\Big\},$$

where $||\cdot||$ is the supremum norm.

Define the mapping $P : S \to S$ by

$$\big(P\varphi\big)(t) = \psi(t) \text{ if } -g_0 \le t \le 0$$

and

$$\big(P\varphi\big)(t) = \Big(\psi(0) - \frac{c(0)}{1-g'(0)}\psi(-g(0))\Big)e^{-\int_0^t a(s)ds} + \frac{c(t)}{1-g'(t)}\varphi(t-g(t))$$
$$+ \int_0^t \Big[-r(s)\varphi(s-g(s)) + \int_{s-g(s)}^s k(s,u)h(x(u))du\Big]e^{-\int_s^t a(u)du}ds,\ t \ge 0,$$

where $r(u)$ is defined by (8.5.9). For $\varphi \in S$ with $||\varphi|| \le L$, we have that for any $\varepsilon > 0$, there exists $t_1 > 0$ such that $t \ge t_1 - g_0$ implies that $|\varphi(t)| < \varepsilon$. Similarly, $t_2 \ge t_1$ and $t \ge t_2 + T$ imply that $e^{-\int_{t_2}^t a(s)ds} < \varepsilon$. Thus $t \ge t_2 + T$ and t_1 large enough give

$$\begin{aligned}
||\big(P\varphi\big)(t)|| &\le |(1 - \frac{c(0)}{1-g'(0)})|\delta\varepsilon + |\frac{c(t)}{1-g'(t)}|\varepsilon \\
&\quad + \int_0^{t_2}\Big[|r(s)|L + \int_{s-g(s)}^s k(s,u)Ldu\Big]e^{-\int_s^{t_2} a(u)du}e^{-\int_{t_2}^t a(u)du}ds \\
&\quad + \int_{t_2}^t \Big[|r(s)|\varepsilon + \int_{s-g(s)}^s |k(s,u)|\varepsilon du\Big]e^{-\int_s^t a(u)du}ds \\
&\quad \le |(1 - \frac{c(0)}{1-g'(0)})|\delta\varepsilon + |\frac{c(t)}{1-g'(t)}|\varepsilon + \varepsilon\alpha L + \varepsilon\alpha.
\end{aligned} \tag{8.5.25}$$

Thus $\big(P\varphi\big)(t) \to 0$ as $t \to \infty$. Also, as in the proof of (8.5.15), with the right choice of δ, we have that $||P(\varphi)|| \le L$ for $||\varphi|| \le L$. It remains to show that P is

Copyright Elsevier 2022

a contraction. For $\zeta, \eta \in S$, we have

$$\begin{aligned}\Big|(P\zeta)(t)-(P\eta)(t)\Big| &\le \Big|\frac{c(t)}{1-g'(t)}\Big|\,||\zeta-\eta|| \\ &+\int_0^t \Big[|r(s)|+\int_{s-g(s)}^{s}|k(s,u)|du\Big]e^{-\int_s^t a(u)du}ds||\zeta-\eta|| \\ &\le \alpha||\zeta-\eta||.\end{aligned}$$

Hence P has a unique fixed point in S. This completes the proof. □

We conclude this section by considering Eq. (8.5.21) when there is no delay in the derivative, that is, $c(t)$ is identically zero. We use the Lyapunov functional method to show that the zero solution is asymptotically stable. As we try to show that the derivative term of the Lyapunov functional is less than zero along the solutions of the desired equation, an unpleasant condition relating the size of $a(t)$ to the size of $g(t)$ arises, which limits the types of equations that can be discussed. In particular, we consider the scalar Volterra integro-differential delay equation

$$x'(t) = -a(t)x(t) + \int_{t-g(t)}^{t} k(t,s)h(x(s))ds, \tag{8.5.26}$$

where $0 \le g(t) \le g_0$ for some constant g_0.

Suppose there exists a positive constant β such that

$$|k(t,s)| \le \beta \text{ for all } t \ge 0, \tag{8.5.27}$$

$$g'(t) \le 1-\beta, \tag{8.5.28}$$

and

$$a(t) \ge \frac{(\beta+1)}{2}g(t) \text{ for all } t \ge 0. \tag{8.5.29}$$

Theorem 8.5.5. *If (8.5.24) and (8.5.27)–(8.5.29) hold, then the zero solution of (8.5.26) is asymptotically stable.*

Proof. Define

$$V(t) = x^2(t) + \int_{t-g(t)}^{t}\int_s^t h^2(x(v))dvds.$$

It follows from (8.5.24) and (8.5.27) that along the solutions of (8.5.26)

$$\begin{aligned}V'(t) &= 2x(t)\Big[-a(t)x(t)+\int_{t-g(t)}^{t}k(t,s)h(x(s))ds\Big] \\ &\quad -(1-g'(t))\int_{t-g(t)}^{t}h^2(x(v))dv + g(t)h^2(x(t))\end{aligned}$$

Copyright Elsevier 2022

$$\begin{aligned}
&\leq -2a(t)x^2(t) + 2\beta|x(t)| \int_{t-g(t)}^{t} |h(x(s))|ds \\
&- (1-g'(t)) \int_{t-g(t)}^{t} h^2(x(s))ds + g(t)h^2(x(t)) \\
&\leq -2a(t)x^2(t) + \beta \int_{t-g(t)}^{t} \Big[x^2(t) + h^2(x(s))ds\Big] \\
&- (1-g'(t)) \int_{t-g(t)}^{t} h^2(x(v))dv + g(t)h^2(x(t)) \\
&\leq x^2(t)\Big[-2a(t) + \beta g(t) + g(t)\Big] + (1-g'(t)+\beta) \int_{t-g(t)}^{t} h^2(x(s))ds \\
&\leq -\gamma x^2(t) \text{ for some positive constant } \gamma.
\end{aligned}$$

Then by (c) of Theorem 8.4.1, the zero solution is asymptotically stable. ☐

8.6 Exponential stability

In this section we consider the scalar and totally nonlinear Volterra integro-differential equation with finite delay

$$x'(t) = -\int_{t-r}^{t} a(t,s)g(x(s))ds, \tag{8.6.1}$$

where $r > 0$ is a constant, and $a : [0,\infty) \times [0,\infty] \to (-\infty,\infty)$. The function $g(x)$ is continuous in x.

The Lyapunov method allowed us to deduce inequalities that all solutions must satisfy and from which we deduce the exponential stability and instability.

Let $\psi : [-r, 0] \to (-\infty,\infty)$ be a continuous initial function with

$$||\psi|| = \max_{-r\leq s\leq 0} |\psi(s)|.$$

It should cause no confusion to denote the norm of a continuous function $\varphi : [-r,\infty) \to (-\infty,\infty)$ by

$$||\varphi|| = \sup_{-r\leq s<\infty} |\varphi(s)|.$$

The notation x_t means that $x_t(\tau) = x(t+\tau)$, $\tau \in [-r, 0]$, as long as $x(t+\tau)$ is defined. Thus x_t is a function mapping an interval $[-h, 0]$ into $\mathbb{R}$. We say that $x(t) \equiv x(t, t_0, \psi)$ is a solution of (8.6.1) if $x(t)$ satisfies (8.6.1) for $t \geq t_0$ and $x_{t_0} = x(t_0 + s) = \psi(s)$, $s \in [-r, 0]$.

Now we turn our attention to the totally nonlinear equation (8.6.1). We will construct a Lyapunov functional $V(t,x) := V(t)$ and show that for some positive α,

Copyright Elsevier 2022

under suitable conditions, $V'(t) \leq -\alpha V(t)$ along the solutions of (8.6.1). To rewrite (8.6.1) so that a suitable Lyapunov functional can be displayed, we let

$$A(t,s) := \int_{t-s}^{r} a(u+s,s)du, \ t,s \geq 0,$$

and assume that

$$A(t,t) = \int_{0}^{r} a(u+t,t)du \geq 0. \tag{8.6.2}$$

In preparation of the main results, we assume that

$$xg(x) \geq x^2 \ \text{ if } \ x \neq 0 \tag{8.6.3}$$

and there exists a positive constant λ such that

$$|g(x)| \leq \lambda |x|. \tag{8.6.4}$$

It is clear that conditions (8.6.3) and (8.6.4) imply that $g(0) = 0$. In addition to the above assumptions, we require that

$$A(t,s)\frac{\partial A(t,s)}{\partial t} \leq 0 \ \text{ for all } \ (t,s) \in [0,\infty) \times [t-r,t]. \tag{8.6.5}$$

Finally, we assume that for $1 < \alpha \leq 2$,

$$A^2\left(t-(\alpha-1)r/\alpha, z\right) \geq A^2(t,z) \tag{8.6.6}$$

for all $t \in [0,\infty)$ and $z \in [t-r/\alpha, t-(\alpha-1)r/\alpha]$. As a consequence of (8.6.5), we have

$$\begin{aligned}
&\int_{-r}^{0}\int_{t+s}^{t} A(t,z)\frac{\partial A(t,z)}{\partial t} g^2(x(z))dz\,ds \\
&= \int_{t-r}^{t}\int_{-r}^{z-t} A(t,z)\frac{\partial A(t,z)}{\partial t} g^2(x(z))ds\,dz \\
&= \int_{t-r}^{t} A(t,z)\frac{\partial A(t,z)}{\partial t} g^2(x(z))(z-t+r)dz \\
&\leq 0,
\end{aligned} \tag{8.6.7}$$

which plays an essential role in the proof of the next lemma. We note that $g(x) = x(\sin^2(x)+1)$ satisfies (8.6.3) and (8.6.4). To construct a suitable Lyapunov functional, we put (8.6.1) in the form

$$x'(t) = -A(t,t)g(x(t)) + \frac{d}{dt}\int_{t-r}^{t} A(t,s)g(x(s))ds. \tag{8.6.8}$$

Copyright Elsevier 2022

Lemma 8.2. *Let* (8.6.2)–(8.6.5) *hold, and suppose that* $0 < r \le 1/2$ *with*

$$\big[(r+1)\lambda^2+1\big]\Big(\int_0^r a(u+t,t)du\Big)^2 \le \int_0^r a(u+t,t)du \le \frac{1-2r}{2r}. \tag{8.6.9}$$

If

$$\begin{aligned} V(t) &= \Big(x(t) - \int_{t-r}^t A(t,s)g(x(s))ds\Big)^2 \\ &\quad + \int_{-r}^0 \int_{t+s}^t A^2(t,z)g^2(x(z))dz\,ds, \end{aligned} \tag{8.6.10}$$

then along the solutions of (8.6.1) *we have*

$$V'(t) \le -A(t,t)V(t).$$

Proof. Let $x(t) = x(t,t_0,\psi)$ be a solution of (8.6.1) and define $V(t)$ by (8.6.10). Then along solutions of (8.6.1) we have

$$\begin{aligned} V'(t) &= 2\Big(x(t) - \int_{t-r}^t A(t,s)g(x(s))ds\Big)[-A(t,t)g(x(t))] \\ &\quad + rA^2(t,t)g^2(x(t)) - \int_{-r}^0 A^2(t,t+s)g^2(x(t+s))ds \\ &\quad + \int_{-r}^0 \int_{t+s}^t 2A(t,z)\frac{\partial A(t,z)}{\partial t}g^2(x(z))dz\,ds \\ &\quad \le -A(t,t)\big[x^2(t) - 2x(t)\int_{t-r}^t A(t,s)g(x(s))ds\big] + r\lambda^2A^2(t,t)x^2(t) \\ &\quad - \int_{-r}^0 A^2(t,t+s)g^2(x(t+s))ds - A(t,t)x^2(t) \ \text{ by (8.5.6)} \\ &\quad - 2A(t,t)x(t)\int_{t-r}^t A(t,s)g(x(s))ds + 2A(t,t)g(x(t))\int_{t-r}^t A(t,s)g(x(s))ds \\ &\quad = -A(t,t)V(t) + A(t,t)\Big(\int_{t-r}^t A(t,s)g(x(s))ds\Big)^2 \\ &\quad - 2A(t,t)x(t)\int_{t-r}^t A(t,s)g(x(s))ds + A(t,t)\int_{-r}^0 \int_{t+s}^t A^2(t,z)g^2(x(z))dz\,ds \\ &\quad + 2A(t,t)g(x(t))\int_{t-r}^t A(t,s)g(x(s))ds \\ &\quad + \big(r\lambda^2A^2(t,t)x^2(t) - A(t,t)x^2(t)\big) \\ &\quad - \int_{-r}^0 A^2(t,t+s)g^2(x(t+s))ds. \end{aligned} \tag{8.6.11}$$

Copyright Elsevier 2022

In what follows, we perform some calculations to simplify (8.6.11). First, if we let $u = t + s$, then

$$-\int_{-r}^{0} A^2(t, t+s)g^2(x(t+s))ds = -\int_{t-r}^{t} A^2(t, s)g^2(x(s))ds. \tag{8.6.12}$$

Also, by Holder's inequality we have that

$$A(t,t)\Big(\int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 \le A(t,t)r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds. \tag{8.6.13}$$

Finally, we easily observe that

$$A(t,t)\int_{-r}^{0}\int_{t+s}^{t} A^2(t,z)g^2(x(z))dz\,ds \le A(t,t)r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds \tag{8.6.14}$$

and

$$\begin{aligned} -2A(t,t)x(t)\int_{t-r}^{t} A(t,s)g(x(s))ds &\le A^2(t,t)x^2(t) \\ &\quad + r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds. \end{aligned} \tag{8.6.15}$$

Similarly,

$$\begin{aligned} 2A(t,t)g(x(t))\int_{t-r}^{t} A(t,s)g(x(s))ds &\le \lambda^2 A^2(t,t)x^2(t) \\ &\quad + r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds. \end{aligned} \tag{8.6.16}$$

Invoking (8.6.12) and substituting expressions (8.6.12)–(8.6.16) into (8.6.11) yield

$$\begin{aligned} V'(t) &\le -A(t,t)V(t) + \big[(r+1)\lambda^2 A^2(t,t) + A^2(t,t) - A(t,t)\big]x^2(t) \\ &\quad + [2rA(t,t) + 2r - 1]\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds \\ &\le -A(t,t)V(t) \text{ by (8.6.9).} \end{aligned} \tag{8.6.17}$$

□

Theorem 8.6.1. *Assume that the hypotheses of Lemma 8.2 and (8.6.6) hold, and let* $1 < \alpha \le 2$. *Then any solution* $x(t) = x(t, t_0, \psi)$ *of (8.6.1) satisfies the exponential*

Copyright Elsevier 2022

inequality

$$|x(t)| \leq \sqrt{2\frac{1+\frac{\alpha-1}{\alpha}}{\frac{\alpha-1}{\alpha}}V(t_0)}e^{-\frac{1}{2}\int_{t_0}^{t-(\frac{\alpha-1}{\alpha})r} A(s,s)ds} \tag{8.6.18}$$

for $t \geq t_0 + (\dfrac{\alpha-1}{\alpha})r$.

Proof. By changing the order of integrations we have

$$\begin{aligned}\int_{-r}^{0}\int_{t+s}^{t} A^2(t,z)g^2(x(z))dz\,ds &= \int_{t-r}^{t}\int_{-r}^{z-t} A^2(t,z)g^2(x(z))ds\,dz \\ = \int_{t-r}^{t} A^2(t,z)g^2(x(z))(z-t+r)dz.\end{aligned} \tag{8.6.19}$$

For $1 < \alpha \leq 2$, if $t - \dfrac{r}{\alpha} \leq z \leq t$, then $(\dfrac{\alpha-1}{\alpha})r \leq z - t + r \leq r$. Expression (8.6.19) yields

$$\begin{aligned}&\int_{-r}^{0}\int_{t+s}^{t} A^2(t,z)g^2(x(z))dz\,ds = \int_{t-r}^{t} A^2(t,z)g^2(x(z))(z-t+r)dz \\ &= \int_{t-r}^{t-\frac{r}{\alpha}} A^2(t,z)g^2(x(z))(z-t+r)dz + \int_{t-\frac{r}{\alpha}}^{t} A^2(t,z)g^2(x(z))(z-t+r)dz \\ &\geq \int_{t-\frac{r}{\alpha}}^{t} A^2(t,z)g^2(x(z))(z-t+r)dz \\ &\geq (\frac{\alpha-1}{\alpha})r\int_{t-\frac{r}{\alpha}}^{t} A^2(t,z)g^2(x(z))dz.\end{aligned} \tag{8.6.20}$$

Let $V(t)$ be given by (8.6.10). Then

$$\begin{aligned}V(t) &\geq \int_{-r}^{0}\int_{t+s}^{t} A^2(t,z)g^2(x(z))dz\,ds \\ &\geq (\frac{\alpha-1}{\alpha})r\int_{t-\frac{r}{\alpha}}^{t} A^2(t,z)g^2(x(z))dz.\end{aligned} \tag{8.6.21}$$

Using (8.6.6), this implies that, for $1 < \alpha \leq 2$,

$$\begin{aligned}V(t-(\alpha-1)r/\alpha) &\geq (\alpha-1)r/\alpha\int_{t-r}^{t-r+r/\alpha} A^2(t,z)g^2(x(z))dz \\ &\geq (\alpha-1)r/\alpha\int_{t-r}^{t-r/\alpha} A^2(t,z)g^2(x(z))dz.\end{aligned} \tag{8.6.22}$$

Copyright Elsevier 2022

Note that since $V'(t) \le 0$, for $t \ge t_0 + (\frac{\alpha-1}{\alpha})r$ we have that

$$0 \le V(t) + V\big(t - (\frac{\alpha-1}{\alpha})r\big) \le 2V\big(t - (\frac{\alpha-1}{\alpha})r\big).$$

In summary, (8.6.11), (8.6.21), and (8.6.22) imply that

$$\begin{aligned}
&V(t) + V\big(t - (\frac{\alpha-1}{\alpha})r\big) \ge \Big(x(t) - \int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 \\
&+ \int_{-r}^{0}\int_{t+s}^{t} A^2(t,z)g^2(x(z))dz\,ds + (\frac{\alpha-1}{\alpha})r\int_{t-r}^{t-\frac{r}{\alpha}} A^2(t,z)g^2(x(z))dz \\
&\ge \Big(x(t) - \int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 + (\frac{\alpha-1}{\alpha})r\int_{t-\frac{r}{\alpha}}^{t} A^2(t,z)g^2(x(z))dz \\
&+ (\frac{\alpha-1}{\alpha})r\int_{t-r}^{t-\frac{r}{\alpha}} A^2(t,z)g^2(x(z))dz \\
&= \Big(x(t) - \int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 + (\frac{\alpha-1}{\alpha})r\int_{t-r}^{t} A^2(t,z)g^2(x(z))dz \\
&\ge \Big(x(t) - \int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 \\
&+ (\frac{\alpha-1}{\alpha})\Big(\int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 \text{ (by Hölder's inequality)} \\
&= \frac{\frac{\alpha-1}{\alpha}}{1+\frac{\alpha-1}{\alpha}}x^2(t) + \Big[\frac{1}{\sqrt{1+\frac{\alpha-1}{\alpha}}}x(t) - \sqrt{1+\frac{\alpha-1}{\alpha}}\int_{t-r}^{t} A(t,s)g(x(s))ds\Big]^2 \\
&\ge \frac{\frac{\alpha-1}{\alpha}}{1+\frac{\alpha-1}{\alpha}}x^2(t).
\end{aligned} \tag{8.6.23}$$

Thus (8.6.23) shows that

$$\begin{aligned}
\frac{\frac{\alpha-1}{\alpha}}{1+\frac{\alpha-1}{\alpha}}x^2(t) &\le V(t) + V\big(t - (\frac{\alpha-1}{\alpha})r\big) \\
&\le 2V\big(t - (\frac{\alpha-1}{\alpha})r\big).
\end{aligned}$$

An integration of (8.6.17) from t_0 to t yields the inequality

$$V(t) \le V(t_0)e^{-\int_{t_0}^{t} A(s,s)ds}.$$

As a consequence,

$$V\big(t - (\frac{\alpha-1}{\alpha})r\big) \le V(t_0)e^{-\int_{t_0}^{t-(\frac{\alpha-1}{\alpha})r} A(s,s)ds},$$

Copyright Elsevier 2022

and

$$|x(t)| \le \sqrt{2\frac{1+\frac{\alpha-1}{\alpha}}{\frac{\alpha-1}{\alpha}} V(t_0) e^{-\frac{1}{2}\int_{t_0}^{t-(\frac{\alpha-1}{\alpha})r} A(s,s)ds}}$$

for $t \ge t_0 + (\dfrac{\alpha-1}{\alpha})r$. This completes the proof. ☐

Remark 8.2. It is clear that inequality (8.6.18) implies that the zero solution of (8.6.1) is asymptotically stable, provided that

$$\int^{\infty} A(t,t)dt \to \infty,$$

and exponentially stable if

$$\int_{t_0}^{t-(\frac{\alpha-1}{\alpha})r} A(s,s)ds \ge \beta(t-t_0)$$

for all $t \ge t_0 + (\dfrac{\alpha-1}{\alpha})r$ and a constant $\beta > 0$.

As an example, we take $g(x) = x(\dfrac{\sin^2(x)}{4} + 1)$. Then $g(0) = 0$, $xg(x) > x^2$, and $|g(x)| \le \dfrac{5}{4}|x|$. Choose $a(t,s) = \dfrac{1}{2}$ and $r = \dfrac{1}{3}$. Next, we make sure that (8.6.7) is satisfied:

$$\int_{-r}^{0}\int_{t+s}^{t} A(t,z)\frac{\partial A(t,z)}{\partial t} g^2(x(z))dz\,ds = -a^2\int_{t-r}^{t}(z-t+r)^2 g^2(x(z))dz \le 0.$$

Thus we have shown that the zero solution of the nonlinear Volterra integro-differential equation

$$x'(t) = -\frac{1}{2}\int_{t-\frac{1}{3}}^{t} x(s)(\frac{\sin^2(x(s))}{4} + 1)ds$$

is exponentially stable.

8.6.1 Instability

We turn our attention to the instability of the zero solution of (8.6.1). We start with the following lemma.

Lemma 8.3. *Suppose (8.6.3), (8.6.4), and (8.6.5) hold and there is a positive constant $D > r$ such that*

$$\frac{r}{r-D} \le A(t,t) \le -A^2(t,t)\big[(1+\lambda)^2 + D\lambda^2\big]. \qquad (8.6.24)$$

Copyright Elsevier 2022

If

$$V(t)=\Big(x(t)-\int_{t-r}^{t}A(t,s)g(x(s))ds\Big)^2$$
$$-D\int_{t-r}^{t}A^2(t,z)g^2(x(z))dz, \tag{8.6.25}$$

then along the solutions of (8.6.1) we have

$$V'(t)\geq -A(t,t)V(t).$$

Proof. Let $x(t)=x(t,t_0,\psi)$ be a solution of (8.6.1) and define $V(t)$ by (8.6.25). Then along solutions of (8.6.1) we have

$$\begin{aligned}
V'(t)&=2\Big(x(t)-\int_{t-r}^{t}A(t,s)g(x(s))ds\Big)[-A(t,t)g(x(t))]\\
&\quad -DA^2(t,t)g^2(x(t))-D\int_{t-r}^{t}2A(t,z)\frac{\partial A(t,z)}{\partial t}g^2(x(z))dz\\
&\geq 2\Big(x(t)-\int_{t-r}^{t}A(t,s)g(x(s))ds\Big)[-A(t,t)g(x(t))]-DA^2(t,t)g^2(x(t))\\
&=-A(t,t)V(t)\\
&\quad -A(t,t)\Big[-\big(\int_{t-r}^{t}A(t,s)g(x(s))ds\big)^2+D\int_{t-r}^{t}A^2(t,z)g^2(x(z))dz\Big]\\
&\quad -2A(t,t)[x(t)-g(x(t))]\int_{t-r}^{t}A(t,s)g(x(s))ds\\
&\quad +\big(-A(t,t)-\lambda^2DA^2(t,t)\big)x^2(t).
\end{aligned}\tag{8.6.26}$$

First, we remark that, as a consequence of (8.6.5), we have

$$-D\int_{t-r}^{t}A(t,z)\frac{\partial A(t,z)}{\partial t}g^2(x(z))dz\geq 0.$$

We note that

$$\begin{aligned}
&2A(t,t)[g(x(t))-x(t)]\int_{t-r}^{t}A(t,s)g(x(s))ds\\
&\leq 2|A(t,t)|(|g(x)|+|x|)|\int_{t-r}^{t}A(t,s)g(x(s))ds|\\
&\leq 2|A(t,t)||x|(1+\lambda)|\int_{t-r}^{t}A(t,s)g(x(s))ds|
\end{aligned}$$

Copyright Elsevier 2022

$$\leq A^2(t,t)(1+\lambda)^2 x^2(t) + \Big(\int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2$$
$$\leq A^2(t,t)(1+\lambda)^2 x^2(t) + r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds.$$

Similarly,

$$A(t,t)\Big(\int_{t-r}^{t} A(t,s)g(x(s))ds\Big)^2 \geq rA(t,t)\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds.$$

Hence (8.6.26) reduces to

$$\begin{aligned}V'(t) &\geq -A(t,t)V(t) - \{A(t,t) + (1+\lambda)^2A^2(t,t) + D\lambda^2A^2(t,t)\}x^2(t)\\ &+ \big[A(t,t)(r-D) - r\big]\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds\\ &\geq -A(t,t)V(t). \end{aligned} \tag{8.6.27}$$

This completes the proof. □

Theorem 8.6.2. *Suppose hypotheses of Lemma 8.3 hold. Then the zero solution of* (8.6.1) *is unstable, provided that*

$$-\int_{t_0}^{\infty} A(s,s)\,ds = \infty.$$

Proof. An integration of (8.6.27) from t_0 to t yields

$$V(t) \geq V(t_0)e^{-\int_{t_0}^{t} A(s,s)\,ds}. \tag{8.6.28}$$

Let $V(t)$ be given by (8.6.25). Then

$$\begin{aligned}V(t) &= x^2(t) - 2x(t)\int_{t-r}^{t} A(t,s)g(x(s))ds + \Big[\int_{t-r}^{t} A(t,s)g(x(s))ds\Big]^2\\ &- D\int_{t-r}^{t} A^2(t,z)g^2(x(z))dz. \end{aligned} \tag{8.6.29}$$

Let $\beta = D - r$. Then from

$$\Big(\frac{\sqrt{r}}{\sqrt{\beta}}a - \frac{\sqrt{\beta}}{\sqrt{r}}b\Big)^2 \geq 0$$

we have

$$2ab \leq \frac{r}{\beta}a^2 + \frac{\beta}{r}b^2.$$

Copyright Elsevier 2022

With this in mind, we arrive at

$$\begin{aligned}-2x(t)\int_{t-r}^{t} A(t,s)g(x(s))ds &\leq 2|x(t)||\int_{t-r}^{t} A(t,s)g(x(s))ds| \\ &\leq \frac{r}{\beta}x^2(t)+\frac{\beta}{r}\Big[\int_{t-r}^{t} A(t,s)g(x(s))ds\Big]^2 \\ &\leq \frac{r}{\beta}x^2(t)+\frac{\beta}{r}r\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds.\end{aligned}$$

A substitution of the above inequality into (8.6.29) yields

$$\begin{aligned}V(t) &\leq x^2(t)+\frac{r}{\beta}x^2(t)+(\beta+r-D)\int_{t-r}^{t} A^2(t,s)g^2(x(s))ds \\ &= \frac{\beta+r}{\beta}x^2(t) \\ &= \frac{D}{D-r}x^2(t).\end{aligned}$$

Using inequality (8.6.28), we get

$$\begin{aligned}|x(t)| &\geq \sqrt{\frac{D-r}{D}}\,V^{1/2}(t) \\ &= \sqrt{\frac{D-r}{D}}\,V^{1/2}(t_0)e^{-\frac{1}{2}\int_{t_0}^{t} A(s,s)\,ds}.\end{aligned}$$

This completes the proof. □

As an example, we take $g(x)=x(\frac{\sin^2(x)}{100}+1)$. Then $g(0)=0$, $xg(x)>x^2$, and $|g(x)|\leq \frac{101}{100}|x|$. Choose $a(t,s)=-\frac{1}{2}$, $r=\frac{1}{8}$, and $D=\frac{1}{4}$. Then (8.6.24) is satisfied. Also, it is clear that (8.6.7) holds.

Thus we have shown that the nonlinear Volterra integro-differential equation

$$x'(t)=\frac{1}{2}\int_{t-\frac{1}{8}}^{t} x(s)(\frac{\sin^2(x(s))}{100}+1)ds$$

is unstable.

We end this section with the following open problem.

Open Problem. In light of this research, what can be said about the exponential stability and instability of the zero solution of the nonlinear Volterra integro-differential equation with infinite delay

$$x'(t)=-\int_{-\infty}^{t} a(t,s)g(x(s))ds?$$

Copyright Elsevier 2022

8.7 Existence of positive periodic solutions

We consider the nonlinear neutral differential equation with functional delay

$$x'(t) = -a(t)x(t) + c(t)x'(t - g(t)) + q(t, x(t - g(t))), \tag{8.7.1}$$

which arises in food-limited population models. For system (8.7.1), there may be a stable equilibrium point of the population. In the case the equilibrium point becomes unstable, there may exist a nontrivial periodic solution. Then the oscillation of solutions occurs. The existence of such a stable periodic solution is of quite fundamental importance biologically since it concerns the long-time survival of species. The study of such phenomena has become an essential part of the qualitative theory of differential equations. One of the most used models, a prototype of (8.7.1), is the system of Volterra integro-differential equations

$$\dot{N}(t) = -\gamma(t)N(t) + \alpha(t)\int_0^\infty B(s)e^{-\beta(t)N(t-s)}ds,$$

where $N(t)$ is the number of red blood cell at time t, $\alpha, \beta, \gamma \in C(\mathbb{R}, \mathbb{R})$ are T-periodic, and $B \in L^1(\mathbb{R}^+)$ is piecewise continuous. This is a generalized model of the red cell system introduced by Wazewska-Czyzewska and Lasota

$$\dot{n}(t) = -\gamma n(t) + \alpha e^{-\beta n(t-r)},$$

where α, β, γ, and r are constants with $r > 0$. The existence of positive periodic solutions was established for the neutral logistic equation with distributed delays

$$x'(t) = x(t)\Big[a(t) - \sum_{i=1}^{n} a_i(t)\int_{-T_i}^{0} x(t+\theta)\,\mathrm{d}\mu_i(\theta) - \sum_{j=1}^{m} b_j(t)\int_{-\hat{T}_j}^{0} x'(t+\theta)\,\mathrm{d}\nu_j(\theta)\Big], \tag{8.7.2}$$

where the coefficients a, a_i, and b_j are continuous periodic functions with the same period. The values $T_i, \hat{T}_j$ are positive, and the functions μ_i, ν_j are nondecreasing with $\int_{-T_i}^{0} \mathrm{d}\mu_i = 1$ and $\int_{-\hat{T}_j}^{0} \mathrm{d}\nu_j = 1$. Eq. (8.7.2) is of logistic form, and hence the method used to obtain the existence of positive periodic solutions will not work for our model (8.7.1). For example, in the above equation the transformation $x(t) = e^{N(t)}$ was used to put (8.7.2) in the form

$$\begin{aligned} N'(t) = a(t) - \sum_{i=1}^{n} a_i(t)\int_{-T_i}^{0} e^{N(t+\theta)}\,\mathrm{d}\mu_i(\theta) \\ - \sum_{j=1}^{m} b_j(t)\int_{-\hat{T}_j}^{0} N'(t+\theta)e^{N(t+\theta)}\,\mathrm{d}\nu_j(\theta). \end{aligned} \tag{8.7.3}$$

Eq. (8.7.1) represents a generalization of the hematopoiesis and blood cell production models.

Copyright Elsevier 2022

The Krasnoselskii fixed point theorem has been extensively used in differential and functional differential equations by Burton [16] to prove the existence of periodic solutions. Also, Burton was the first to use the theorem to obtain stability results regarding solutions of integral equations and functional differential equations. For a collection of different type of results, we refer the reader to [16] and the references therein. The author is unaware of any results regarding the use of Krasnoselskii to prove the existence of a positive periodic solution.

Theorem 8.7.1. *(Krasnoselskii) Let* $\mathbb{M}$ *be a closed convex nonempty subset of a Banach space* $\big(\mathbb{B}, \|\cdot\|\big)$. *Suppose that* A *and* B *map* $\mathbb{M}$ *into* $\mathbb{B}$ *and satisfy the following conditions:*

- **(i)** A *is compact and continuous,*
- **(ii)** B *is a contraction mapping,*
- **(iii)** *If* $x, y \in \mathbb{M}$, *then* $Ax + By \in \mathbb{M}$.

Then there exists $z \in \mathbb{M}$ *such that* $z = Az + Bz$.

For $T > 0$, define $P_T = \{\phi \in C(\mathbb{R}, \mathbb{R}), \phi(t+T) = \phi(t)\}$, where $C(\mathbb{R}, \mathbb{R})$ is the space of all real-valued continuous functions. Then P_T is a Banach space when endowed with the supremum norm

$$\|x\| = \max_{t\in[0,T]} |x(t)| = \max_{t\in\mathbb{R}} |x(t)|.$$

We assume that

$$a(t+T) = a(t), \;\; c(t+T) = c(t), \;\; g(t+T) = g(t), \;\; g(t) \geq g^* > 0 \tag{8.7.4}$$

with continuously differentiable $c(t)$, twice continuously differentiable $g(t)$, and constant g^*. Usually, $a(t)$ is assumed to be positive, but here we only require that

$$\int_0^T a(s)ds > 0. \tag{8.7.5}$$

It is interesting to note that Eq. (8.7.1) becomes of advanced type when $g(t) < 0$. Since we are searching for periodic solutions, it is natural to require that $q(t, x)$ is continuous in both arguments and periodic in t. Also, we assume that for all $0 \leq t \leq T$,

$$g'(t) \neq 1. \tag{8.7.6}$$

Lemma 8.4. *Suppose* (8.7.4)–(8.7.6) *hold. If* $x(t) \in P_T$, *then* $x(t)$ *is a solution of Eq.* (8.7.1) *if and only if*

$$\begin{aligned} x(t) = {} & \frac{c(t)}{1-g'(t)} x(t-g(t)) \\ & + \int_t^{t+T} \Big[-r(u)x(u-g(u)) + q(u, x(u-g(u)))\Big] \frac{e^{\int_t^u a(s)ds}}{e^{\int_0^T a(s)ds} - 1}\, du, \end{aligned} \tag{8.7.7}$$

Copyright Elsevier 2022

where

$$r(t) = \frac{\Big(c'(t) + c(t)a(t)\Big)\Big(1 - g'(t)\Big) + g''(t)c(t)}{(1 - g'(t))^2}. \tag{8.7.8}$$

Proof. Let $x(t) \in P_T$ be a solution of (8.7.1). Multiply both sides of (8.7.1) with $e^{\int_0^t a(s)ds}$ and then integrate from t to $t + T$ to obtain

$$\int_t^{t+T} \Big[x(u)e^{\int_0^u a(s)ds}\Big]' du = \int_t^{t+T} \Big[c(u)x'(u - g(u)) \\ + q(u, x(u), x(u - g(u)))\Big] e^{\int_0^u a(s)ds} du.$$

As a consequence, we arrive at

$$x(t + T)e^{\int_0^{t+T} a(s)ds} - x(t)e^{\int_0^t a(s)ds} \\ = \int_t^{t+T} \Big[c(u)x'(u - g(u)) + q(u, x(u - g(u)))\Big] e^{\int_0^u a(s)ds} du.$$

By dividing both sides of the above equation by $e^{\int_0^{t+T} a(s)ds}$ and the fact that $x(t + T) = x(t)$ we obtain

$$x(t) = \Big(1 - e^{-\int_t^{t+T} a(s)ds}\Big)^{-1} \int_t^{t+T} \Big[c(u)x'(u - g(u)) \\ + q(u, x(u), x(u - g(u)))\Big] e^{-\int_u^{t+T} a(s)ds} du. \tag{8.7.9}$$

Rewrite

$$\int_t^{t+T} c(u)x'(u - g(u))e^{-\int_u^{t+T} a(s)ds} du \\ = \int_t^{t+T} \frac{c(u)x'(u - g(u))(1 - g'(u))}{(1 - g'(u))} e^{-\int_u^{t+T} a(s)ds} du.$$

Integrating by parts the above integral with

$$U = \frac{c(u)}{1 - g'(u)} e^{-\int_u^{t+T} a(s)ds}$$

and

$$dV = x'(u - g(u))(1 - g'(u))du,$$

Copyright Elsevier 2022

we obtain

$$\int_t^{t+T} c(u)x'(u-g(u))e^{-\int_u^{t+T} a(s)ds}du = \frac{c(t)}{1-g'(t)}x(t-g(t))\Big(1-e^{-\int_t^{t+T} a(s)ds}\Big)$$
$$-\int_t^{t+T} r(u)e^{-\int_u^{t+T} a(s)ds}x(u-g(u))du,$$

where $r(u)$ is given by (8.7.8). Finally, due to the integration over one period and the periodicity of all functions, we have that

$$\frac{e^{-\int_u^{t+T} a(s)ds}}{1-e^{-\int_t^{t+T} a(s)ds}} = \frac{e^{-\int_u^{t+T} a(s)ds}}{e^{-\int_t^{t+T} a(s)ds}(e^{\int_t^{t+T} a(s)ds}-1)}$$
$$= \frac{e^{\int_t^u a(s)ds}}{e^{\int_t^{t+T} a(s)ds}-1} = \frac{e^{\int_t^u a(s)ds}}{e^{\int_0^T a(s)ds}-1}.$$

This completes the proof. □

To simplify notation, we let

$$M = \frac{e^{\int_0^{2T} |a(s)|ds}}{e^{\int_0^T a(s)ds}-1} \tag{8.7.10}$$

and

$$m = \frac{e^{-\int_0^{2T} |a(s)|ds}}{e^{\int_0^T a(s)ds}-1}. \tag{8.7.11}$$

Let

$$G(t,u) = \frac{e^{\int_u^t a(s)ds}}{e^{\int_0^T a(s)ds}-1}. \tag{8.7.12}$$

It is easy to see that for all $(t,u) \in [0,2T] \times [0,2T]$,

$$m \le G(t,u) \le M,$$

and for all $t, u \in \mathbb{R}$, we have

$$G(t+T, u+T) = G(t,u).$$

We obtain the existence of a positive periodic solution by considering two cases:

(a) $0 \le \dfrac{c(t)}{1-g'(t)} < 1,$

and

(b) $-1 \le \dfrac{c(t)}{1-g'(t)} \le 0.$

Copyright Elsevier 2022

For some nonnegative constant L and positive constant K, we define the set

$$\mathbb{M} = \{\phi \in P_T : L \le ||\phi|| \le K\},$$

which is a closed convex bounded subset of the Banach space P_T. In addition, we assume that there are constants $0 \le \beta \le \alpha < 1$ such that

$$0 \le \beta \le \frac{c(t)}{1 - g'(t)} \le \alpha < 1, \tag{8.7.13}$$

and for all $u \in \mathbb{R}$ and $\rho \in \mathbb{M}$,

$$\frac{(1-\beta)L}{mT} \le q(s,\rho) - r(s)\rho \le \frac{(1-\alpha)K}{MT}, \tag{8.7.14}$$

where M and m are defined by (8.7.10) and (8.7.11), respectively. To apply Theorem 8.7.1, we need to construct two mappings: one is a contraction, and the other is compact. Thus we define the map $\mathbf{A} : \mathbb{M} \to P_T$ by

$$(\mathbf{A}\varphi)(t) = \int_t^{t+T} G(t,s)[q(s,\varphi(s-g(s))) - r(s)\varphi(s-g(s))]\,ds, t \in \mathbb{R}. \tag{8.7.15}$$

In a similar way, we set the map $\mathbf{B} : \mathbb{M} \to P_T$ by

$$(\mathbf{B}\varphi)(t) = \frac{c(t)}{1-g'(t)}\varphi(t-g(t)), t \in \mathbb{R}. \tag{8.7.16}$$

It is clear from condition (8.7.13) that $\mathbf{B}$ defines a contraction mapping under the supremum norm.

Lemma 8.5. *If* (8.7.4)–(8.7.6)*,* (8.7.13)*, and* (8.7.14) *hold, then the operator* $\mathbf{A}$ *is completely continuous on* $\mathbb{M}$*.*

Proof. For $t \in [0,T]$, which implies that $u \in [t, t+T] \subseteq [0, 2T]$, and for $\varphi \in \mathbb{M}$, we have by (8.7.13) that

$$\begin{aligned}|(\mathbf{A}\varphi)(t)| &\le \| \int_t^{t+T} G(t,s)[q(s,\varphi(s-g(s))) - r(s)\varphi(s-g(s))]\,ds\| \\ &\le TM\frac{(1-\alpha)K}{MT}.\end{aligned}$$

From the estimate of $|\mathbf{A}\varphi(t)|$ it follows that

$$||\mathbf{A}\varphi(t)|| \le (1 - \frac{c(t)}{1-g'(t)})K \le Q_1$$

for some positive constant Q_1. This shows that $\mathbf{A}(\mathbb{M})$ is uniformly bounded. It remains to show that $\mathbf{A}(\mathbb{M})$ is equicontinuous. Let $\varphi \in \mathbb{M}$. Then a differentiation of

Copyright Elsevier 2022

(8.7.13) with respect to t yields

$$(\mathbf{A}\varphi)'(t) = G(t,t+T)[q(t,\varphi(t-g(t))) - r(t)\varphi(t-g(t))] + a(t)(\mathbf{A}\varphi)(t).$$

Hence by taking the supremum norm in the above expression we have

$$||(\mathbf{A}\varphi)'|| \le \frac{Q_1}{T} + ||a(t)||Q_1.$$

Thus the estimation on $|(\mathbf{A}\varphi)'(t)|$ implies that $\mathbf{A}(\mathbb{M})$ is equicontinuous. Then by the Ascoli–Arzelà theorem, we obtain that A is a compact map. Due to the continuity of all terms in (8.7.13) for $t \in [0,T]$, we have that $\mathbf{A}$ is continuous. This completes the proof. □

Theorem 8.7.2. *If* (8.7.4)–(8.7.6), (8.7.13), *and* (8.7.14) *hold, then Eq.* (8.7.1) *has a positive periodic solution* z *satisfying* $L \le z \le K$.

Proof. Let $\varphi, \psi \in \mathbb{M}$. Then by (8.7.13) and (8.7.16) we have that

$$\begin{aligned}(\mathbf{B}\varphi)(t) + (\mathbf{A}\psi)(t) &= \frac{c(t)}{1-g'(t)}\varphi(t-g(t)) \\ &\quad + \int_t^{t+T} G(t,s)[q(s,\varphi(s-g(s))) - r(s)\varphi(s-g(s))]\,ds \\ &\le \alpha K + MT\frac{(1-\alpha)K}{MT} = K.\end{aligned}$$

On the other hand,

$$\begin{aligned}(\mathbf{B}\varphi)(t) + (\mathbf{A}\psi)(t) &= \frac{c(t)}{1-g'(t)}\varphi(t-g(t)) \\ &\quad + \int_t^{t+T} G(t,s)[q(s,\varphi(s-g(s))) - r(s)\varphi(s-g(s))]\,ds \\ &\ge \beta L + m\int_t^{t+T}[q(s,\varphi(s-g(s))) - r(s)\varphi(s-g(s))]\,ds \\ &\ge \beta L + mT\frac{(1-\beta)L}{mT} = L.\end{aligned}$$

This shows that $\mathbf{B}\varphi + \mathbf{A}\psi \in \mathbb{M}$. All the hypotheses of Theorem 8.7.1 are satisfied, and therefore Eq. (8.7.1) has a periodic solution, say z, residing in $\mathbb{M}$. This completes the proof. □

For the next theorem, we assume that there are constants $-1 < \beta \le \alpha \le 0$ such that

$$-1 < \beta \le \frac{c(t)}{1-g'(t)} \le \alpha \le 0, \tag{8.7.17}$$

Copyright Elsevier 2022

and for all $u \in \mathbb{R}$ and $\rho \in \mathbb{M}$,

$$\frac{(L-\beta K)}{mT} \le q(s,\rho) - r(s)\rho \le \frac{(K-\alpha L)}{MT}, \tag{8.7.18}$$

where M and m are defined by (8.7.10) and (8.7.11), respectively.

Theorem 8.7.3. *If* (8.7.4)–(8.7.6), (8.7.17), *and* (8.7.18) *hold, then Eq.* (8.7.1) *has a positive periodic solution z satisfying $L \le z \le K$.*

Proof. The proof follows along the lines of Theorem 8.7.2, and hence we omit it. ☐

Example 8.5. The neutral differential equation

$$x'(t) = -\frac{1}{2}\sin^2(t)x(t) + \frac{1}{50}x'(t-\pi) + \frac{\cos^2(t)}{x^2(t-\pi)+100} + \frac{1}{25} \tag{8.7.19}$$

has a positive π-periodic solution x satisfying

$$\frac{1}{10} \le x \le 2.$$

To see this, we let

$$q(s,\rho) = \frac{\cos^2(s)}{\rho^2+100} + \frac{1}{25}, \ r(s) = \frac{1}{2}\sin^2(s), \quad \text{and} \quad T = g(t) = \pi.$$

Then

$$\frac{c(t)}{1-g'(t)} = \frac{1}{50} < 1,$$

and

$$r(t) = \frac{1}{100}\sin^2(t).$$

A simple calculation yields

$$4.030 < M < 4.032 \ \text{ and } \ 1.74 < m < 1.75.$$

Let $K=2$ and $L=\frac{1}{10}$, and define the set $\mathbb{M} = \{\frac{1}{10} \le \upsilon \le 2\}$. Then for $\rho \in [\frac{1}{10}, 2]$, we have

$$\begin{aligned} q(s,\rho) - r(s)\rho &= \frac{\cos^2(s)}{\sigma^2+100} + \frac{1}{100}\sin^2(s)\rho + \frac{1}{25} \\ &\le \frac{1}{100} + \frac{1}{50} + \frac{1}{25} = 0.07 < \frac{(1-\frac{c(t)}{1-g'(t)})K}{MT}. \end{aligned}$$

Copyright Elsevier 2022

On the other hand,

$$q(s,\rho) - r(s)\rho = \frac{\cos^2(u)}{\sigma^2+100} + \frac{1}{100}\sin^2(u)\rho + \frac{1}{25}$$
$$> \frac{1}{25} > \frac{(1-\frac{c(t)}{1-g'(t)})L}{mT}.$$

We see that all the conditions of Theorem 8.7.2 are satisfied, and hence (8.7.19) has a positive π-periodic solution x satisfying $\frac{1}{10} \le x \le 2$.

8.8 Exercises

Exercise 8.1. Use the method of steps to find the solution of the delay differential equation with delay 1,

$$x' = -tx(t-1),\ t > 0;\ x(s) = \varphi(s) = 12,\ \ -1 \le s \le 0,$$

on the interval [0, 3] by considering the subintervals [0, 1], [1, 2], and [2, 3].

Exercise 8.2. Consider the delay differential equation with delay 1,

$$x' = ax(t) + bx(t-1),\ t > 0,$$

with initial function

$$x(s) = \varphi(s) = 1 + t,\ \ -1 \le s \le 0,$$

where a and $b \neq 0$ are constants. Use the method of steps to find the solution on the interval $[0, 2]$ by considering the subintervals $[0, 1]$ and $[1, 2]$. Is the solution differentiable at the initial time $t_0 = 0$? What about the differentiability at $t = 1$?

Exercise 8.3. Consider the delay differential equation with delay 1,

$$x' = x(t) + x(t-1),\ t > 0,$$

with initial function

$$x(s) = \varphi(s) = t,\ \ -1 \le s \le 0.$$

Use the method of steps to find the solution on the interval $[0, 3]$. Is the solution differentiable at the initial time $t_0 = 0$? What about the differentiability at $t = 1$?

Exercise 8.4. Solve the Bernoulli equation (8.2.5).

Exercise 8.5. Repeat Example 8.3 for the delay second-order differential equation

$$mu''(t) + bu'(t) + qu'(t-r) + cu(t) = 0,\ t \ge 0,$$

where m, b, q, c, and r are positive constants.

Copyright Elsevier 2022

Exercise 8.6. Consider the delay second-order differential equation

$$u''(t)+au'(t)+bu'(t-r)=0,\ t\geq 0,$$

where a, b, and r are positive constants. Write the delay equation into a system in x and y and use the Lyapunov-type functional

$$V(x_t, y_t)=y^2+bx^2+\gamma\int_{-r}^{0}\int_{t+s}^{t} y^2(u)du\,ds,\quad \gamma>0.$$

(i) Show that if

$$\gamma=b \text{ and } -a+br<0,$$

then the zero solution is uniformly stable.
(ii) Choose

$$\gamma>b \text{ and } \frac{-2a}{r}+\gamma+b<0$$

and show that the zero solution is asymptotically stable and uniformly asymptotically stable.

Exercise 8.7. Give an example of application of Theorem 8.7.3.

Exercise 8.8. Consider the delay differential equation

$$x'(t)=-ax(t)+bx(t-r),\ t\geq t_0\geq 0,$$

where a, b, and r are positive constants. Consider the Lyapunov-type functional

$$V(x_t)=x^2(t)+b\int_{t-r}^{t} x^2(s)ds.$$

(i) Show that if $a\geq b$, then all solutions are bounded, and the zero solution is uniformly stable.
(ii) Show that if $a>b$, then the zero solution is uniformly asymptotically stable, and $x^2(t)\in L^1[0,\infty)$.
(iii) Use part (i) to show that all solutions of

$$x'(t)=-2x(t)+x(t-\tau),\ x(t)=\varphi(s),\ -\tau\leq s\leq 0,\ t\geq 0,$$

are bounded.
(iv) Replace the delay term $x(t-\tau)$ in the delay differential equation given in (iii) with

$$x(t)-\tau x'(t)+\frac{1}{2}\tau^2 x''$$

and show that the solutions of the resulting equation are unbounded regardless of the size of the delay τ.

Copyright Elsevier 2022

Exercise 8.9. Consider the finite delay differential equation

$$x'(t) = -3x(t) + \frac{1}{e}x(t-1), \ t \geq 0, \tag{8.8.1}$$

with $x(t) = \varphi(s)$, $-1 \leq s \leq 0$.
(a) Use Theorem 8.4.3 to show that all solutions of (8.8.1) are bounded and its zero solution is exponentially stable.
(b) Replace the delay term $x(t-1)$ in (8.8.1) with $x(t) - x'(t)$. Are the solutions of the resulting equation bounded?
(c) Now replace the delay term $x(t-1)$ in (8.8.1) with $x(t) - x'(t) + \frac{1}{2}x''$ and show that the solutions of the resulting equation are unbounded.

Exercise 8.10. Construct an example that satisfies the hypotheses of Theorem 8.5.5.

Exercise 8.11. Let $h > 0$ and consider the finite delay differential equation

$$x'(t) = a(t)x(t) + b(t)x(t-h) + g(t), \ t \geq 0, \tag{8.8.2}$$

with $x(t_0) = \varphi$. Suppose $a(t)$, $b(t)$, and $g(t)$ are continuous for all $t \geq 0$. For some $\tau > 0$, define the continuous function

$$\xi(t) = \frac{e^{\int_0^t c(s)ds}}{1 + 2h\int_t^{t+\tau} e^{\int_0^u c(s)ds} du} \geq 0 \tag{8.8.3}$$

with

$$|b(t)| \leq h\xi(t), \tag{8.8.4}$$

where $c(t) := 2a(t) + |g(t)|$. Use the functional

$$V(t, x_t) = x^2(t) + h\xi(t)\int_{t-h}^{t} x^2(s)\, ds$$

to show that every solution of (8.8.2) with $x(t_0) = \varphi$ satisfies the inequality

$$||x(t)|| \leq \left[V(t_0, \varphi) + \int_{t_0}^{t} |g(u)|\, e^{\int_{t_0}^{u} \alpha(s)ds}\, du\right]^{1/2} e^{-\frac{1}{2}\int_{t_0}^{t} \alpha(s)ds},$$

where $\alpha(t) = c(t) + 2h\xi(t)$ and $V(t_0, \varphi) = \varphi^2(0) + h\xi(t_0)\displaystyle\int_{t_0-h}^{t_0} \varphi^2(s)ds$.

Exercise 8.12. (Big project) Develop similar results as in Section 8.6 for the totally delayed differential equation

$$x' = ax(t-r), \ t > 0,$$

where $a \in \mathbb{R}$, and r is a positive constant.

Copyright Elsevier 2022

CHAPTER

New variation of parameters

9

In this chapter we introduce *new variation of parameters formula* and apply the idea to ordinary and delay differential equations. The results of this chapter are totally new and should serve as foundations for future research.

9.1 Applications to ordinary differential equations

It is customary in a nonlinear differential equation to add and subtract a convenient term that allows us to invert the equation in question and obtain a variation of parameters formula, which can be used to obtain different results on the solutions. However, the added term will cause restrictions on the coefficients, and as a result, limit the class of equations that can be considered. In this section we adopt the terminologies of Chapter 2 with respect to definitions of solutions and other important matters. We just try to avoid redundancies and repetitions. Consider the simplest ordinary differential equation

$$x'(t) = ax(t), \quad x(0) = x_0, \tag{9.1.1}$$

which has the solution

$$x(t) = x_0 e^{at} \to 0 \text{ as } t \to \infty,$$

provided that

$$a < 0.$$

Suppose $a : \mathbb{R} \to \mathbb{R}$ is continuous and consider the ordinary differential equation with variable coefficient

$$x'(t) = a(t)x(t), \quad x(0) = x_0, \tag{9.1.2}$$

which has the solution

$$x(t) = x_0 e^{\int_0^t a(s)ds} \to 0 \text{ as } t \to \infty,$$

provided that

$$\int_0^t a(s)ds \to -\infty. \tag{9.1.3}$$

Advanced Differential Equations. https://doi.org/10.1016/B978-0-32-399280-0.00015-2

Copyright © 2023 Elsevier Inc. All rights reserved.

Copyright Elsevier 2022

Condition (9.1.3) implies that the function $a(t)$ can be positive or oscillates for a short time. Now let

$$v : [0, \infty) \to \mathbb{R}$$

be a continuous function. Multiply both sides of (9.1.1) by

$$e^{\int_0^t v(s)ds}$$

and then integrate from 0 to any $t \in [0, T)$:

$$\int_0^t e^{\int_0^u v(s)ds}\, x'(u)du = \int_0^t ax(u)e^{\int_0^u v(s)ds}du.$$

Integrating by parts the left side and simplifying, we get

$$x(t) = x_0 e^{-\int_0^t v(s)ds} + \int_0^t x(u)\big(v(u) + a\big)e^{-\int_u^t v(s)ds}du. \tag{9.1.4}$$

Expression (9.1.4) is a *new variation of parameters formula for* (9.1.1) and of Volterra-type integral equation. Note that if

$$v(t) = -a,$$

then (9.1.4) becomes the regular solution $x(t) = x_0 e^{at}$ of (9.1.1). In a similar fashion,

$$x'(t) = a(t)x(t), \ \ x(0) = x_0,$$

has the solution

$$x(t) = x_0 e^{-\int_0^t v(s)ds} + \int_0^t x(u)\big(v(u) + a(u)\big)e^{-\int_u^t v(s)ds}du. \tag{9.1.5}$$

Again, letting

$$v(t) = -a(t),$$

we get the regular known solution $x(t) = x_0 e^{\int_0^t a(s)ds}$, and $x(t) \to 0$ as $t \to \infty$, provided that

$$\int_0^t a(s)ds \to -\infty.$$

Again, (9.1.5) is a new variation of parameters formula that we will analyze when considering nonlinear equations. In the mean time, for (9.1.5), by setting up the proper spaces and using the contraction mapping principle, we can show that $x(t) \to 0$ as $t \to \infty$, provided that

$$\int_0^t \big|v(u) + a(u)\big|e^{-\int_u^t v(s)ds}du \le \alpha, \ 0 < \alpha < 1,$$

Copyright Elsevier 2022

and

$$\int_0^t v(s)ds \to \infty.$$

Suppose $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous and consider the nonlinear differential equation

$$x'(t) = f(t, x(t)),\ x(0) = x_0,\ \text{for a given constant } x_0. \tag{9.1.6}$$

Then multiplying by a function $\int_0^t v(s)ds$ the solution of (9.1.6) is given by

$$x(t) = x_0 e^{-\int_0^t v(s)ds} + \int_0^t \big(x(u)v(u) + f(u, x(u))\big)e^{-\int_u^t v(s)ds}du. \tag{9.1.7}$$

Next, we will use (9.1.7) to define a mapping on the proper space and show that the zero solution is AS. Let $\mathscr{C}$ be the set of all real-valued continuous functions. Define the space

$$\mathscr{S} = \{\phi : [0, \infty) \to \mathbb{R}/\phi \in \mathscr{C},\ |\phi(t)| \le L,\ \phi(t) \to 0 \text{ as } t \to \infty\}.$$

Then

$$(\mathscr{S}, ||\cdot||)$$

is a complete metric space under the uniform metric

$$\rho(\phi_1, \phi_2) = ||\phi_1 - \phi_2||,$$

where

$$||\phi|| = \sup\{|\phi(t)| : t \ge 0\}.$$

Let f be locally Lipschitz on the set $\mathscr{S}$, such that

$$f(t, 0) = 0, \tag{9.1.8}$$

that is, for any ϕ_1 and $\phi_2 \in \mathscr{S}$, we have

$$|f(t, \phi_1) - f(t, \phi_2)| \le \lambda(t)||\phi_1 - \phi_2|| \tag{9.1.9}$$

with continuous $\lambda : [0, \infty) \to (0, \infty)$. Assume that for $\phi \in \mathscr{S}$, we have that

$$|x_0|e^{-\int_0^t v(s)ds} + L\int_0^t \big(|v(u)| + \lambda(u)\big)e^{-\int_u^t v(s)ds}du \le L. \tag{9.1.10}$$

Note that (9.1.10) implies that

$$\int_0^t \big(|v(u)| + \lambda(u)\big)e^{-\int_u^t v(s)ds}du \le \alpha < 1.$$

Copyright Elsevier 2022

Theorem 9.1.1. *Assume* (9.1.8)–(9.1.10). *Suppose there exists a positive constant* k *such that*

$$e^{-\int_0^t v(s)ds} \leq k. \tag{9.1.11}$$

Then the unique solution of (9.1.6) *is bounded, and its zero solution is stable.*

If, in addition,

$$\int_0^t v(s)ds \to \infty, \tag{9.1.12}$$

then the zero solution of (8.5.2) *is asymptotically stable.*

Proof. For $\phi \in \mathscr{S}$, define the mapping $\mathfrak{P} : \mathscr{S} \to \mathscr{S}$ by

$$(\mathfrak{P}\phi)(t) = x_0 e^{-\int_0^t v(s)ds} + \int_0^t \big(\phi(u)v(u) + f(u, \phi(u))\big)e^{-\int_u^t v(s)ds}du. \tag{9.1.13}$$

It is clear that $(\mathfrak{P}\phi)(0) = x_0$. Now for $\phi \in \mathscr{S}$, we have that

$$\big|(\mathfrak{P}\phi)(t)\big| \leq |x_0|k + \int_0^t \big(|\phi(u)||v(u)| + \lambda(u)|\phi(u)|\big)e^{-\int_u^t v(s)ds}du.$$

Consequently,

$$\|\mathfrak{P}\phi\| \leq |x_0|k + \int_0^t \big(|v(u)| + \lambda(u)\big)e^{-\int_u^t v(s)ds}du||\phi||,$$

and

$$\|\mathfrak{P}\phi\| \leq |x_0|k + \alpha\|\phi\| \leq L, \text{ due to (9.1.10) and } \phi \in \mathscr{S}. \tag{9.1.14}$$

Since $\mathfrak{P}$ is continuous, we have that $\mathfrak{P} : \mathscr{S} \to \mathscr{S}$. Next, we show that $\mathfrak{P}$ is a contraction.

For $\phi_1, \phi_2 \in \mathscr{S}$, from (9.1.13) we have that

$$\begin{aligned}\big|(\mathfrak{P}\phi_1)(t) - (\mathfrak{P}\phi_2)(t)\big| &\leq \int_0^t \big(|v(u)| + \lambda(u)\big)e^{-\int_u^t v(s)ds}du||\phi_1 - \phi_2|| \\ &\leq \alpha||\phi_1 - \phi_2||.\end{aligned}$$

This shows that $\mathfrak{P}$ is a contraction. By Banach's contraction mapping principle, $\mathfrak{P}$ has a unique fixed point $x \in \mathscr{S}$, which is a bounded continuous function. Moreover, the unique fixed point is a solution of (9.1.6) on $[0, \infty)$. Let x be the unique solution. Let $\varepsilon > 0$ and choose $\delta = \varepsilon\frac{1-\alpha}{k}$. If $|x_0| < \delta$, then by (9.1.14) we have that

$$(1-\alpha)||x|| \leq |x_0|k < \delta k$$

or

$$||x|| \leq \varepsilon.$$

Copyright Elsevier 2022

The proof of

$$|x(t)| \to 0 \text{ as } t \to \infty$$

rests on condition (9.1.12), and we refer to the proof of Theorem 8.5.2. This completes the proof. □

To see the benefits of our new inversion method, we consider a particular nonlinear equation and rewrite it so that we can invert the usual way. Consequently, the *contraction mapping principle* will no longer work. Let

$$f(t,x) = -x^3 + h(t,x),$$

where $h(t,x)$ satisfies a smallness condition. Thus we consider

$$x' = -x^3 + h(t,x). \tag{9.1.15}$$

Due to the absence of a linear term, we borrow one and try to invert the old way. We write (9.1.15) in the form

$$x' = -x + (x - x^3) + h(t,x) \tag{9.1.16}$$

and then use the variation of parameters formula to obtain

$$x(t) = x_0 e^{-t} + \int_0^t e^{-(t-s)}[x(s) - x^3(s) + h(s,x(s))]ds. \tag{9.1.17}$$

It is naive to believe that most maps can be defined so that they are contractions, even with the strictest conditions. To that effect, consider

$$g(x) = x - x^3.$$

Then for $x, y \in \mathbb{R}$ with $|x|, |y| \leq \frac{\sqrt{3}}{3}$, we have that

$$|g(x) - g(y)| = |x - x^3 - y + y^3| \leq |x - y|\left(1 - \frac{x^2 + y^2}{2}\right),$$

and the contraction constant tends to 1 as $x^2 + y^2 \to 0$. As a consequence, the regular contraction mapping principle failed to produce any results. Using (9.1.7), (9.1.15) has the solution

$$x(t) = x_0 e^{-\int_0^t v(s)ds} + \int_0^t \big(x(u)v(u) - x^3(u) + h(u,x(u))\big)e^{-\int_u^t v(s)ds}du. \tag{9.1.18}$$

Now using the contraction mapping principle, we would have to show that a function of the form

$$f(x) = v(r)x - x^3$$

Copyright Elsevier 2022

is a contraction. This is true on some bounded and small set, provided that v is of sufficiently small magnitude.

Thus using (9.1.18) we can easily obtain stability and boundedness results regarding (9.1.15) under the right conditions.

9.1.1 Periodic solutions

Next, we apply our new method to linear or nonlinear differential equations to show the existence of periodic solutions without the requirement of some classic conditions. To better illustrate our approach, we let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ and $a : \mathbb{R} \to \mathbb{R}$ be continuous and consider the nonlinear differential equation

$$x' = a(t)x(t) + f(t, x), \tag{9.1.19}$$

where f is continuous in x. For $T \in R$, we assume the periodicity condition

$$a(t+T) = a(t) \text{ and } f(t+T, \cdot) = f(t, \cdot). \tag{9.1.20}$$

Let BC be the space of continuous bounded functions $\phi : \mathbb{R} \to \mathbb{R}$ with the maximum norm $||\cdot||$. Define

$$P_T = \{\phi \in BC, \phi(t+T) = \phi(t)\}.$$

Then P_T is a Banach space endowed with the maximum norm

$$\|x\| = \max_{t\in[0,T]} |x(t)|.$$

Also, we assume that

$$e^{\int_0^T a(s)ds} \neq 1. \tag{9.1.21}$$

Throughout this section, we assume that $a(t) \neq 0$ for all $t \in [0, T]$. Now (9.1.19) is equivalent to

$$\left[x(t)e^{-\int_0^t a(s)ds}\right]' = f(t, x(t))e^{-\int_0^t a(s)ds}.$$

Integrating this expression from $t-T$ to t and using the fact that $x(t-T) = x(t)$ give

$$x(t) = \left(1 - e^{\int_0^T a(s)ds}\right)^{-1} \int_{t-T}^{t} f(u, x(u))e^{\int_u^t a(s)ds} du. \tag{9.1.22}$$

Theorem 9.1.2. *Assume* (9.1.20) *and* (9.1.21). *Suppose the function f is Lipschitz continuous with Lipschitz constant k. If*

$$k\left|\left(1 - e^{\int_0^T a(s)ds}\right)^{-1}\right| \int_{t-T}^{t} e^{\int_u^t a(s)ds} du \leq \alpha$$

for $\alpha \in (0, 1)$, then (9.1.19) *has a unique periodic solution.*

Copyright Elsevier 2022

Proof. Define $\mathfrak{P}$ by the right side of (9.1.22). It is easily verified that $(\mathfrak{P}\phi)(t+T) = (\mathfrak{P}\phi)(t)$, and hence $\mathfrak{P} : P_T \to P_T$. The rest of the proof is a direct application of the contraction mapping principle on the set P_T. ☐

On the other hand, if we take a function $v(t)$ as before and assume that $v \in P_T$ with $v(t) \neq 0$ for all $t \in [0, T]$, then we obtain the following variation of parameters formula:

$$\begin{aligned} x(t) = \left(1 - e^{\int_0^T v(s)ds}\right)^{-1} \int_{t-T}^{t} \Big[& x(u)v(u) + x(u)a(u) \\ & + f(u, x(u)) e^{\int_u^t a(s)ds} du \Big]. \end{aligned} \tag{9.1.23}$$

Theorem 9.1.3. *Suppose $v(t) \neq 0$ for all $t \in [0, T]$ and the function f is Lipschitz continuous with Lipschitz constant k. If*

$$\left| \left(1 - e^{\int_0^T v(s)ds}\right)^{-1} \right| \int_{t-T}^{t} [|a(r)| + |v(r)| + k] \left| e^{\int_u^t a(s)ds} du \right| \leq \alpha$$

for $\alpha \in (0, 1)$, then (9.1.19) *has a unique periodic solution.*

Proof. The proof is similar to that of Theorem 9.1.2. ☐

Note that (9.1.23) can now handle equations of the form

$$x'(t) = \cos(t)x(t) + f(t, x(t)).$$

We easily see that

$$1 - e^{\int_0^T a(s)ds} = 1 - e^{\int_0^{2\pi} \cos(s)ds} = 0,$$

and hence (9.1.22) cannot be used.

9.2 Applications to delay differential equations

We begin by considering the following totally delayed nonlinear differential equation:

$$x'(t) = a(t)l(x_r), \tag{9.2.1}$$

where $x_r(t) = x(t - r)$ for $r > 0$ constant, and $l = l(t)$ is a continuous function satisfying some conditions to be imposed later. Let $\psi : [-r, 0] \to \mathbb{R}$ be a continuous initial function. We rewrite (9.2.1) in the form

$$x'(t) = a(t + r)l(x) - \frac{d}{dt} \int_{t-r}^{t} a(s + r)l(x(s))ds$$

Copyright Elsevier 2022

$$\begin{aligned}&= a(t+r)x(t) - a(t+r)[x(t) - l(x(t))]\\ &- \frac{d}{dt}\int_{t-r}^{t} a(s+r)l(x(s))ds. \qquad (9.2.2)\end{aligned}$$

Note that we added and subtracted $a(t+r)x$, so that the inversion is possible. Thus by the variation of parameters formula we obtain the integral

$$\begin{aligned}x(t) &= \psi(0)e^{\int_0^t a(s+r)ds}\\ &- \int_0^t e^{\int_s^t a(u+r)du} a(s+r)[x(s) - l(x(s))]ds\\ &- \int_0^t e^{\int_s^t a(u+r)du} \frac{d}{ds}\int_{s-r}^{s} a(u+r)l(x(u))du\, ds. \qquad (9.2.3)\end{aligned}$$

The appearance of the term $x(s) - l(x(s))$ in (9.2.3) is a direct consequence of the borrowed term. In addition, to get any meaningful results, we would have to assume that $l(x(t))$ is odd. Otherwise, $x(s) - l(x(s))$ will not define a contraction. Next, we invert our way by assuming $\nu : [0, \infty) \to \mathbb{R}$ to be a nonnegative continuous function such that $0 < \int_0^\infty \nu(s)\,ds = m < \infty$. To solve (9.2.1), we apply an inversion technique that starts by multiplying both sides by $e^{\int_0^t \nu}$ and then integrates them. We simplify the notation here and drop the ds at the end of the exponent:

$$\int_0^t e^{\int_0^s \nu} x'(s)ds = x(t)e^{\int_0^t \nu} - x(0) - \int_0^t x\nu e^{\int_0^s \nu}\, ds.$$

Therefore (9.2.1) becomes

$$x(t)e^{\int_0^t \nu} = x(0) + \int_0^t x\nu e^{\int_0^s \nu}\, ds + \int_0^t e^{\int_0^s \nu} a(s)l(x_r)\, ds,$$

$$x(t) = x(0)e^{-\int_0^t \nu} + \int_0^t x\nu e^{-\int_s^t \nu}\, ds + \int_0^t e^{-\int_s^t \nu} a(s)l(x_r)\, ds. \qquad (9.2.4)$$

By imposing adequate conditions on $\nu(t)$, $a(t)$, and $l(t)$, we will prove the existence of bounded solutions to (9.2.1). To this end, we will use the right-hand side to define a contraction map on a complete metric space $\mathscr{S}$. The resulting unique fixed point will be the solution we are looking for. Let $K > 0$ be a constant and fix an initial continuous function $\Psi : [-r, 0] \to \mathbb{R}$ with $|\Psi(t)| < K$ for $t \in [-r, 0]$ and $|\Psi(0)| > 0$. Define the space

$$\mathscr{S} := \{x : [-r, \infty) \to \mathbb{R} \mid x \in \mathscr{C}^1[-r, \infty),\ \|x\|_\infty \le K,\ x \equiv \Psi \text{ on } [-r, 0]\}, \qquad (9.2.5)$$

where $\mathscr{C}^1[-r, \infty)$ denotes the space of continuously differentiable functions, and $\|\cdot\|_\infty$ is the supremum norm. By general principles, it follows that $\mathscr{S}$ is a complete

Copyright Elsevier 2022

metric space. Define the map $\mathfrak{P}$ on $\mathscr{S}$ by

$$\mathfrak{P}(x) := x(0)e^{-\int_0^t \nu} + \int_0^t x\nu e^{-\int_s^t \nu}\, ds + \int_0^t e^{-\int_s^t \nu} a(s) l(x_r)\, ds. \tag{9.2.6}$$

The following lemma can be adapted to several different situations.

Lemma 9.1. *Let* $\{\varepsilon_1, \varepsilon_2, \varepsilon_3\}$ *be a triple of positive numbers such that* $\varepsilon_1 + \varepsilon_2 + \varepsilon_3 \leq 1 - \delta$ *for fixed* $0 < \delta < 1$. *Assume that* $|\Psi(0)| \leq \varepsilon_1 K$ *and* m *is small enough such that* $|1 - e^{-m}| < \varepsilon_2$. *Assume that* $l(y)$ *is Lipschitz on* $[-K, K]$ *and satisfies* $|l(y)| \leq C_l |y|$ *for* $y \in [-K, K]$ *and for some positive constant* C_l. *Suppose that* $a \in L^1([0, \infty))$ *and* $\int_0^\infty |a(s)|\, ds \leq \frac{\varepsilon_3}{C_l}$. *Then the map* $\mathfrak{P}$ *has range in* $\mathscr{S}$ *and is a contraction. This implies that* (9.2.1) *has a unique solution in* $\mathscr{S}$.

Proof. We use the hypotheses of the theorem to bound each of the summands on the right-hand side of (9.2.6). The first term satisfies the bound

$$\left| x(0)e^{-\int_0^t \nu} \right| \leq \varepsilon_1 K,$$

since $|e^{-\int_s^t \nu}| \leq 1$. The second summand can be bounded by

$$\left| \int_0^t x\nu e^{-\int_s^t \nu}\, ds \right| \leq \|x\|_\infty \int_0^t \nu e^{-\int_s^t \nu}\, ds \leq (1 - e^{-m})\|x\|_\infty \leq \varepsilon_2 K.$$

The conditions stated above allow us to bound the third summand by

$$\left| \int_0^t e^{-\int_s^t \nu} a(s) l(x_r)\, ds \right| \leq \varepsilon_3 \|x\|_\infty \leq \varepsilon_3 K.$$

Therefore

$$|\mathfrak{P}(x)| \leq K\varepsilon_1 + K\varepsilon_2 + K\varepsilon_3 \leq (1 - \delta)K. \tag{9.2.7}$$

This implies $\|\mathfrak{P}(x)|\|_\infty \leq (1 - \delta)K$ so that $\mathfrak{P}$ has the range in $\mathscr{S}$.
The contraction part follows similarly:

$$\begin{aligned} |\mathfrak{P}(x) - \mathfrak{P}(y)| &\leq |x - y| \left(\int_0^t \nu e^{-\int_s^t \nu} ds + C_l \int_0^t |a(s)|\, ds \right) \\ &\leq |x - y| \left(\varepsilon_2 + C_l \frac{\varepsilon_3}{C_l} \right) \\ &\leq (1 - \delta)|x - y|. \end{aligned} \tag{9.2.8}$$

Therefore $\|\mathfrak{P}(x) - \mathfrak{P}(y)\|_\infty \leq (1 - \delta)\|x - y\|_\infty$, and $\mathfrak{P} : \mathscr{S} \to \mathscr{S}$ is a contraction. ☐

Now we consider a slightly more general equation

$$x'(t) = a(t) g(x_r) + b(t) G(x_r), \tag{9.2.9}$$

Copyright Elsevier 2022

where a, b, g, G are all continuous on $[-r, \infty)$. Let us denote the right-hand side of (9.2.9) by $L(x_r)$. On the same space $\mathscr{S}$ as before, we define the new map

$$\hat{\mathfrak{P}}(x) := x(0)e^{-\int_0^t \nu} + \int_0^t x\nu e^{-\int_s^t \nu}\,ds + \int_0^t e^{-\int_s^t \nu} L(x_r)\,ds. \tag{9.2.10}$$

Impose the same conditions on ν as in Lemma 9.1. The only difference now is the third term. We impose the following conditions:

C1- The functions g and G are Lipschitz on $[-K, K]$. Explicitly, there are positive constants C_g and C_G such that $|g(y)| \le C_g|y|$ and $|G(y)| \le C_G|y|$ for all $y \in [-K, K]$.

C2- $a, b \in L^1([0, \infty))$, $\int_0^\infty |a(s)|\,ds \le \frac{\varepsilon_3}{2C_g}$, and $\int_0^\infty |b(s)|\,ds \le \frac{\varepsilon_3}{2C_G}$.

Lemma 9.2. *Using the notation and definitions from Lemma 9.1, under conditions C1–C2, the map $\hat{\mathfrak{P}} : \mathscr{S} \to \mathscr{S}$ is a contraction.*

Proof. The only difference is the third summand in the definition of $\hat{\mathfrak{P}}$. We bound it as follows:

$$\left|\int_0^t e^{-\int_s^t \nu} L(x_r)\,ds\right| \le K\left(C_g \frac{\varepsilon_3}{2C_g} + C_G \frac{\varepsilon_3}{2C_G}\right) = K\varepsilon_3,$$

and the rest follows similarly to the proof of Lemma 9.1. □

As a consequence, we find that (9.2.9) has a unique bounded solution in $\mathscr{S}$.

9.2.1 The main inversion

Now we present a more general way of inverting (9.2.9), which starts by rewriting it as

$$\begin{aligned} x'(t) &= (a+b)g(x_r) + b(G(x_r) - g(x_r)) \\ &= -\frac{d}{dt}\int_{t-r}^t c(p+r)g(x(p))\,dp + c(t+r)g(x(t)) + bl(x_r), \end{aligned} \tag{9.2.11}$$

where $c = a + b$ and $l = G - g$. Now multiply both sides by $e^{\int_0^t \nu}$ and integrate as before to solve for $x(t)$. We get

$$\begin{aligned} x(t) =& x(0)e^{-\int_0^t \nu} + \int_0^t x\nu e^{-\int_s^t \nu} ds \\ &- \int_0^t e^{-\int_s^t \nu}\left(\frac{d}{ds}\int_{s-r}^s c(p+r)g(x(p))\,dp\right) ds \\ &+ \int_0^t c(s+r)g(x)e^{-\int_s^t \nu} ds + \int_0^t e^{-\int_s^t \nu} bl(x_r) ds. \end{aligned} \tag{9.2.12}$$

Copyright Elsevier 2022

Apply integration by parts in the middle line to get

$$\begin{aligned} x(t) = x(0)e^{-\int_0^t \nu} &+ \int_0^t x\nu e^{-\int_s^t \nu} ds \\ &- F(t) + e^{-\int_0^t \nu} F(0) + \int_0^t \nu e^{-\int_s^t \nu} F(s)\, ds \\ &+ \int_0^t c(s+r)g(x)e^{-\int_s^t \nu} ds + \int_0^t e^{-\int_s^t \nu} bl(x_r) ds, \end{aligned} \tag{9.2.13}$$

where $F(t) = \int_{t-r}^t c(p+r)g(x(p))dp$.

Again, we consider the same space $\mathscr{S}$ and define the new map

$$\begin{aligned} \mathfrak{P}(x) = x(0)e^{-\int_0^t \nu} &+ \int_0^t x\nu e^{-\int_s^t \nu} ds \\ &- F(t) + e^{-\int_0^t \nu} F(0) + \int_0^t \nu e^{-\int_s^t \nu} F(s)\, ds \\ &+ \int_0^t c(s+r)g(x)e^{-\int_s^t \nu} ds + \int_0^t e^{-\int_s^t \nu} bl(x_r) ds. \end{aligned} \tag{9.2.14}$$

We need to impose a different set of conditions on the summands on the right-hand side of (9.2.14) to get a contraction mapping of $\mathscr{S}$. First, label the terms on the right-hand side as 1–7. The new bounds on the absolute values the terms now are as follows:

D1- The first two summands are bounded exactly as before, that is, $x(0) = \Psi(0) \le \varepsilon_1 K$ and $\|\nu\|_{L^1} = m > 0$, so that $1 - e^{-m} \le \varepsilon_2$.

D2- To bound $F(t)$, assume that $\int_0^\infty |c|\, dt \le \int_0^\infty |a|\, dt + \int_0^\infty |b|\, dt \le \frac{\varepsilon_3}{C_g + C_G}$. Here C_g and C_G are the Lipschitz constants of the delayed functions. The third and fourth terms are each bounded above by $\varepsilon_3 K$.

D3- The definitions above produce an upper bound for the fifth term equal to $m\varepsilon_3 K$, where $m = \int_0^\infty |\nu| dt$.

D4- The sixth term is again bounded above by $\varepsilon_3 K$.

D5- The upper bound on b above implies that the seventh term is also bounded above by $\varepsilon_3 K$.

Therefore

$$|\mathfrak{P}(x)| \le K(\varepsilon_1 + \varepsilon_2 + (m+4)\varepsilon_3). \tag{9.2.15}$$

Theorem 9.2.1. *If the bounds D1–D5 above hold and there is* $0 < \delta < 1$ *such that* $\varepsilon_1 + \varepsilon_2 + (m+4)\varepsilon_3 \le 1 - \delta$, *then the map* $\mathfrak{P} : \mathscr{S} \to \mathscr{S}$ *is a contraction with a unique fixed point. This fixed point is a solution to* (9.2.9) *that belongs to* $\mathscr{S}$.

Example 9.1. Let $\alpha, \beta > 0$ be such that

$$\dot{x} = e^{-\alpha t} g(x_r) + e^{-\beta t} G(x_r), \tag{9.2.16}$$

Copyright Elsevier 2022

where α and β are big enough so that $\alpha^{-1}+\beta^{-1} \leq \frac{\varepsilon_3}{C_g+C_G}$. This equation satisfies the previous conditions. Eq. (9.2.16) is a first-order differential equation with exponentially damped time-delayed terms. Theorem 9.2.1 implies the existence of a solution to (9.2.16) in $\mathscr{S}$.

9.2.2 Variable time delay

Here we consider $r = r(t)$ variable. We impose conditions on it later on. We want to find solutions to

$$x'(t) = a(t)g(x(t-r(t))) + b(t)G(x(t-r(t))). \tag{9.2.17}$$

We still denote $x(t-r(t))$ by x_r. The same strategy as before gives

$$\begin{aligned} x'(t) &= (a+b)g(x_r) + b(G(x_r) - g(x_r)) \\ &= c(t)g(x_r) + bl(x_r) \\ &= \frac{cg(x_r)}{1-r'}(1-r') + bl(x_r). \end{aligned} \tag{9.2.18}$$

Denote $f = \frac{c}{1-r'}$ and $f_r = f(t-r(t))$. Now we rewrite (9.2.18) as follows:

$$\begin{aligned} x' &= f_r g(x_r)(1-r') + (f(t) - f_r)g(x_r)(1-r') + bl(x_r) \\ &= \big(f_r g(x_r)(1-r') - f(t)g(x(t))\big) + f(t)g(x(t)) \\ &\quad + (f(t) - f_r)g(x_r)(1-r') + bl(x_r) \\ &= -\Big(\frac{d}{dt}\int_{t-r(t)}^{t} f(s)g(x(s))ds\Big) + f(t)g(x(t)) \\ &\quad + (f(t) - f_r)g(x_r)(1-r') + bl(x_r). \end{aligned} \tag{9.2.19}$$

To simplify the upcoming expression, assume that $r(0) = 0$. The inversion gives

$$\begin{aligned} x(t) &= x(0)e^{-\int_0^t \nu} + \int_0^t x\nu e^{-\int_s^t \nu} ds \\ &\quad - \int_{t-r(t)}^{t} f(p)g(x(p))dp + \int_0^t \nu e^{-\int_s^t \nu} \int_{s-r(s)}^{s} f(p)g(x(p))dpds \\ &\quad + \int_0^t e^{-\int_s^t \nu}\big(f(s)g(x(s)) + (f(s) - f_r)g(x_r)(1-\dot{r}) + bl(x_r)\big)ds. \end{aligned} \tag{9.2.20}$$

The most important condition to be imposed on r is $|r'(t)| \leq \kappa < 1$ for some κ small and positive. This condition allows us to get uniform pointwise upper bounds on the function $f = \frac{c}{1-r'}$. From the definition of $\mathscr{S}$ we impose that $r(t) \leq r$ for all $t \geq 0$. Now we impose bounds on the different terms.

E1- The first two summands are bounded exactly as before, that is, $x(0) = \Psi(0) \leq \varepsilon_1 K$ and $\|\nu\|_{L^1} = m > 0$, so that $1 - e^{-m} \leq \varepsilon_2$.

Copyright Elsevier 2022

E2- To bound $f(t)$, assume that

$$\int_{-r}^{\infty} |f|\,dt \le (1-\kappa)^{-1} \int_{-r}^{\infty} |c|\,dt \le (1-\kappa)^{-1} \left(\int_{0}^{\infty} |a|\,dt + \int_{0}^{\infty} |b|\,dt \right)$$
$$\le \frac{\varepsilon_3}{(1-\kappa)(C_g + C_G)}.$$

This suffices to bound all the terms in the last line as well.

Theorem 9.2.2. *Define the map* $\mathfrak{P}$ *on* $\mathscr{S}$ *by the right-hand side of* (9.2.20). *Suppose there are constants* $\{\varepsilon_1, \varepsilon_2, \varepsilon_3\}$ *such that bounds E1–E2 above are satisfied and such that* $\varepsilon_1 + \varepsilon_2 + \frac{2\kappa+4}{1-\kappa}\varepsilon_3 \le 1 - \delta$ *for some* $0 < \delta < 1$. *Then* $\mathfrak{P} : \mathscr{S} \to \mathscr{S}$ *is a contraction. This implies that* (9.2.17) *has a unique solution in* $\mathscr{S}$.

9.3 Exercises

Exercise 9.1. Give the details for the proof of Theorem 9.1.3.

Exercise 9.2. Use our new inversion to show the existence of periodic solutions to

$$x'(t) = a(t)g(x) + b(t)G(t, x_L), \tag{9.3.1}$$

where $x_L = x(t-L)$, and $a(t), b(t)$ are continuous periodic functions with period $L > 0$. We assume that $g = g(t,x) = g(t+L,x)$ and $G = G(t,x) = G(t+L,x)$. We also assume that g and G are Lipschitz on $[0, L]$ (and extended periodically) with constants C_g and C_G, respectively.

Exercise 9.3. Consider the equation

$$x'(t) = -a(t)x(t) + c(t)x'(t-g(t)) + q(t, x(t-g(t))). \tag{9.3.2}$$

For $T > 0$, define $P_T = \{\phi \in C(\mathbb{R},\mathbb{R}), \phi(t+T) = \phi(t)\}$, where $C(\mathbb{R},\mathbb{R})$ is the space of all real-valued continuous functions. Then P_T is a Banach space endowed with the supremum norm

$$\|x\| = \max_{t\in[0,T]} |x(t)| = \max_{t\in\mathbb{R}} |x(t)|.$$

Assume that

$$a(t+T) = a(t), \quad c(t+T) = c(t), \quad g(t+T) = g(t), \quad g(t) \ge g^* > 0 \tag{9.3.3}$$

with continuously differentiable $c(t)$, twice continuously differentiable $g(t)$, and constant g^*. We suppose that $q(t,x)$ is continuous in both arguments and periodic in t. Usually, $a(t)$ is assumed to be positive, but here we only assume that

$$\int_0^T a(s)ds > 0.$$

Copyright Elsevier 2022

Choose a positive function $\nu(t) = \nu(t+T)$. Multiply both sides of (9.3.2) by $e^{\int_0^t \nu}$ and integrate by parts between $t-T$ and t.
(i) Obtain a variation of parameters formula.
(ii) Use the results of part (i) to define a mapping $\mathfrak{P}$ on $P_T = \{\phi \in C(\mathbb{R}, \mathbb{R}), \phi(t+T) = \phi(t)\}$ and show that $\mathfrak{P} : P_T \to P_T$.
(iii) Impose additional conditions and prove theorems parallels to Theorems 8.7.2 and 8.7.3.
